MAN has been defined by some naturalists as an *exchanging animal*—an animal who buys and sells—that being an act performed by no other living creature, and therefore suitable as a distinction in character, though others, much more exalted, might readily be found. The practice of exchanging one commodity for another is doubtless coeval with the first herding of mankind together. No man, even in the rudest savage state, and who lives in the society of neighbours, can rest satisfied with such objects as he can procure or fashion by his own labour. He must depend on others for assistance, while he assists them in return. The cultivator of the ground would exchange some of its produce for an animal from the flocks of his neighbour; and both would be glad to give a portion of their wealth for the clothing or weapons made by a third party. Thus *exchanging* becomes a matter of convenience between two parties, each of whom is anxious to obtain a share of the other's goods for a share of his own, and a mutual advantage is the result. Such desires and practices must have been displayed in the very earliest stages of society. No nation of African or Indian savages is ever found without a strong inclination to exchange the rude products of their country for the articles possessed by the traveller; an ox or sheep being perhaps eagerly offered by them for a single needle, a nail, or a small toy looking-glass.

As mankind advance in their social condition, the practice of exchanging increases; the desires and necessities become more urgent; each person finds it more profitable and agreeable to adopt and hold by one fixed employment, and to sell the produce of his labour for a variety of articles made by others, than to attempt to make everything for himself; and finally, for the sake of convenience, a class of persons are engaged to conduct the exchanges from one hand to another. In this improved condition, the production of articles of general consumption is called *manufacturing*; while that department of industry in which the exchanging is transacted is called *trade* or *commerce*. For still further convenience, the business of exchanging is committed to several orders of traders—the wholesale merchants, who in the first instance purchase large quantities of goods from the producers; the retail dealers, who have been supplied in smaller quantities from the merchants, and sell individual articles or minute portions to the public; and to these sometimes an intermediate dealer is added. In this manner the transfer from the workshop of the manufacturer to the house of the actual consumer is interrupted by several distinct processes of exchange, in which each seller obtains a certain profit at the expense of the person who has ultimately to buy and use the article. It is a principle of trade, that the fewer hands through which any article is made to pass the better for the consumer, because the article can be brought with the least burthen of profits, or at the lowest price, into general use. But this principle, sound as it is in the abstract, is counteracted by another, which must on no account be lost sight of. This is the principle of *convenience*. A manufacturer engaged deeply in his own pursuits finds it more profitable and agreeable to sell his articles in large than small quantities. The maker of millions of yards of cloth has no time to spend in selling single yards. If he were compelled to sell by retail, he would have no time to conduct his affairs; he could manufacture only a small quantity, and therefore being limited in his amount of produce and sales, he must take larger profits. Thus, upon the whole, it is

No. 82.

much better for all concerned to allow the manufacturer to pursue his own way in selling only very large quantities to wholesale merchants. To these traders the same rule may be applied. They seek out the seats of manufacture, and purchasing a large variety of goods, they send them to the towns and places where they are required by the public, and there the articles can be had individually from a shop. It is evident that if any man wish to buy a handkerchief, he may procure it much more cheaply from any shop in which such things are sold at an advance upon the original cost, than if he were to travel perhaps hundreds of miles to the house of the manufacturer, and there make the purchase. The use of an intermediate class to conduct exchanges is thus very conspicuous; and any attempt to revert generally to the original practice of causing the maker to deal with the consumer, would be entirely incompatible with an enlarged system of trade between different countries, or even between different places in the same country. We say generally, because there are instances in which makers may, with advantage to themselves and the community, sell their produce in small quantities or single articles to the public; but these are exceptions to a common rule.

*Convenience*—which is for the most part but another name for time, or labour, or capital—forms, it is evident, a guiding principle of trade, and requires the same consideration as the actual value of an article. This, however, has been recognised only in very recent times. At one period there were laws to prevent farmers from selling their grain in a large quantity or by the lump, without exposing it in an open market. Such laws were manifestly unjust. They interfered with the liberty of the farmer, who, in his capacity of manufacturer, had surely a right to sell his produce in whichever way he felt it to be most for his advantage. It would be the same kind of injustice if the law, for example, were to prevent a manufacturer of handkerchiefs from selling them at his own workshop to wholesale dealers, and causing him to take them many miles to a certain street in a certain town, and there expose them for sale in small lots to the public. It is of the greatest importance in matters of trade and commerce *never to interfere in any shape to prevent men from dealing in whatever manner appears most beneficial and convenient to themselves, provided it be conformable with strict justice*. Sellers, of whatever grade, being left to consult their own interest and inclinations, the public in the end, though probably in a way not easily recognisable by an unreflecting mind, reaps the advantage.

Commerce, by which we comprehend traffic carried on at home or with foreign countries, is of great antiquity, and both in the earliest times and in our own day has been one of the principal engines of civilisation. Among the industrious nations which at a remote period of history were planted on the borders of the Mediterranean Sea, it became a means of spreading knowledge in the interior of Asia, and many parts of Africa and Europe. Unfortunately, the intelligence which was so disseminated was afterwards obliterated by the overruling powers of barbarous and warlike nations; but the efficacy of commerce in modern times is likely to be permanent wherever its influence is extended, seeing that the greatest manufacturing and mercantile people are at the same time the most powerful and most capable of offering protection to those who sustain a commercial intercourse with them. It is exceedingly pleasing thus to reflect on what commerce is capable of effecting, independent of the actual comfort which it produces wherever it is fairly introduced. By its appeals to the selfishness, the vanity, and other passions, good and bad, of mankind, it appears to be the

been remarkably exempted in the boundless regions of Hindoostan, which, by the efforts of a company of merchants, have been laid open to the settlement of enlightened men from Europe, who, though by slow degrees, will ultimately spread the blessings of education and the decencies of social life among many millions of human beings. In the remote islands in the Pacific Ocean, the influence of commerce has been recently of marked utility. The introduction of articles of a fanciful nature, both for the ornamenting and covering of the person, has induced a desire of following European manners and customs; and as these commodities cannot be procured but by the exchange of native commodities, a spirit of industry has consequently been produced which cannot fail to be of both moral and physical advantage to the natives. It is always thus with the intercourse which commerce necessarily involves. New tastes are created, and to be gratified industry must be exerted. But to witness the extraordinary influence of commerce in producing civilised and refined habits, we need not look beyond our own country. Commerce, in this its chosen seat, has caused roads everywhere to be cut, canals to be opened, railways to be formed, expeditious modes of travelling and communicating by sea and land to be effected; all of which great accessories to our comfort have tended in the most wonderful manner to introduce not only useful commodities and personal luxuries, but highly cultivated sentiments, literature, and the arts, into districts which at no distant period lay in a comparatively primitive condition. The intercourse which commerce in this manner requires is the grand lever which, it is apparent, must in the first place be employed to lift the load of ignorance from off the natives of Africa and other barbarous regions; and when this lever is properly insinuated, the way will soon be prepared for the introduction of those measures of melioration which philanthropists so anxiously design.

It is obvious that this scheme of mutual interchange among nations of the commodities which they respectively produce is agreeable to every rational principle, and must have been designed by a wise Providence for the universal benefit of His creatures. In order that manufactures may be produced, and commerce brought in to disseminate them both at home and abroad where they are wanted, no species of legislative enactment is requisite either to encourage or direct. The law which governs production and consumption is a law of nature—it is the overruling principle of *self-interest*, by which only that quantity of manufactures is produced which can be advantageously disposed of, and only those commodities purchased and consumed which the wants of individuals require. And curiously enough, this principle of self-interest, if allowed free scope, is uniformly and sufficiently competent to regulate both the production and consumption of commodities, to a degree more nice and satisfactory than could be attained by the best devised statutes which the wisest legislators could enact. The grand principle, therefore, which can alone regulate commerce and manufactures is found in the natural passion for gain; and the sole essential requisite for the successful advancement of mercantile and manufacturing industry and wealth among any people, is for that people to be unfettered by enactments; each one buying and selling when, where, and at what price he pleases.

Evident as these principles must be to all who have any knowledge of social life, they have, either from ignorance or some other cause, been generally lost sight of by governments in all ages of the world, and plans have been contrived to regulate that which, if left alone, would have much better regulated itself. To such an extent have regulating and restrictive laws been carried in some countries, that they have nearly annihilated both manufactures and legitimate commerce, and reduced masses of the people to the condition of paupers, besides encouraging the pernicious and demoralising

mercer do not perhaps originate so much in the plea that manufacturers and merchants stand in the condition of children, and require to be taken care of lest they should hurt themselves, as from the unfortunate exigencies under which the governments happen to be placed. They have all less or more engaged in wars, which have been conducted at an enormous expense to their respective countries. In order to liquidate these expenses, all kinds of taxes are levied, directly and indirectly; but as the levying of these taxes breeds discontent, large bodies of military have usually to be kept up, to act as an armed national police. Thus the people of these countries have for ages to go on paying not only the price of the wars, or the interest of the sums borrowed and laid out upon the wars, but as much more for the military force afterwards imposed upon them. What is more distressing, the people have probably to give a deal of money, in order that their respective governments may be the more able to secure the attachment of men of consequence to assist in allaying the general clamours for a redress of grievances. This is a very rough view of the matter, but it is enough to show the dreadful exigencies into which nations fall by their engaging in wars or other expensive follies. In whatever manner, however, national exigencies originate, the plan pursued for relief consists chiefly in the imposition of duties on certain commodities much in demand, and at various stages of their manufacture, transmission, and sale. It is likewise customary to impose duties on goods imported from foreign countries, with the view of protecting the manufacturers of such articles in this country; but this only benefits a class, or a few persons, at the expense of the whole community, and therefore all such duties are in the main as detrimental to trade and the public welfare as those imposed for the liquidation of national debt and expenditure. For further observations in relation to this subject, we refer to the article *POLITICAL ECONOMY*. 'There is,' observes Mr M'Culloch in his 'Dictionary of Commerce,' 'no jugglery in commerce. Whether it be carried on between individuals of the same country, or of different countries, it is in all cases bottomed on a fair principle of reciprocity. Those who will not buy need not expect to sell, and conversely. It is impossible to export without making a corresponding importation. We get nothing from the foreigner gratuitously; and hence, when we prevent the importation of produce from abroad, we prevent by the very same act the exportation of an equal amount of British produce. All that the exclusion of foreign commodities ever effects, is the substitution of one sort of demand for another. It has been said, that "when we drink beer and porter we consume the produce of English industry, whereas, when we drink port or claret we consume the produce of the industry of the Portuguese and French, to the obvious advantage of the latter, and the prejudice of our countrymen!" But how paradoxical soever the assertion may at first sight appear, there is not at bottom any real distinction between the two cases. What is it that induces foreigners to supply us with port and claret? The answer is obvious:—We either send directly to Portugal and France an equivalent in British produce, or we send such equivalent, in the first place, to South America for bullion, and then send that bullion to the continent to pay for the wine. And hence it is as clear as the sun at noonday, that the Englishman who drinks only French wine, who eats only bread made of Polish wheat, and who wears only Saxon cloth, gives, by occasioning the exportation of a corresponding amount of British cotton, hardware, leather, or other produce, the same encouragement to the industry of his countrymen that he would were he to consume nothing not immediately produced at home. A quantity of port wine and a quantity of Birmingham goods are respectively of the same value; so that whether we directly consume the hardware, or having exchanged it for the wine, consume the latter, in so far as the

employment of British or native labour is concerned it is altogether indifferent.'

From these explanations, it will be observed that it is immaterial what is given in exchange for imported goods—whether money or native produce. At the same time it must be understood that if money is given, there must exist some active industry in the country by which the money is realised. As a general question in commerce, it is of no consequence what is the nature of the industry by which the money is produced. It may consist in the raising of superabundant crops, or other raw produce for exportation, or of manufacturing raw and comparatively valueless materials into articles of value and demand, or of carrying goods from one country to another. Unless a country possess one or more of these branches of industry, it is without the means of paying for imported articles, and must retire from the field of general commerce. England is not of sufficiently large dimensions to export superabundant crops of grain, but it possesses in an extraordinary degree the means of manufacturing mineral and other substances into articles for exchange, and it derives no inconsiderable profit from the carrying of commodities. Its manufactured goods, therefore, pay for imports of foreign articles, including bullion or the raw material of money, and these again, in a manufactured state, are a fund for the payment of still further imports. Thus the wealth of our country has increased.

PRINCIPLES OF COMMERCE.

The practice of commerce is in a great measure dependent on mutual good faith, and the integrity of seller and buyer, and can in no case permanently flourish where these fundamental qualities are wanting. The first or great leading quality, therefore, in the character of a merchant ought to be scrupulous honesty both in word and deed. The article which he proposes to dispose of must be exactly what he declares it to be, not inferior or in any respect unsound in its nature. If it possess any blemishes, these must be announced to the buyer before the bargain is concluded, and if necessary, though at a considerable loss, an allowance made for them. The merchant is not less called on to be faithful in the fulfilment of all promises which he may make, whether with respect to goods or their payment; because those to whom the promises have been made may on that account have made similar promises to others, and therefore the breaking of a single promise may prove injurious in every link of a whole train of transactions. Perfect honesty or integrity is a fundamental principle of trade; and the next most important are strict regularity in all proceedings, according to established usage, and also steady perseverance. The merchant must give regular attendance during the hours of business; be regular in executing all orders and answering all letters; regular in the keeping of his books, and in the reckoning of his stock and monies; in short, he must be methodic and careful in all branches of his concerns, for without this species of attention the best business is apt to become confused, and to be ultimately ruined. What is true of individuals holds true also when applied to a whole nation. No people have ever attained opulence and high mercantile consideration who have not possessed a character for integrity and regularity in all their dealings.

Besides these indispensable qualities in the individual character of a merchant or tradesman, there is required a happy combination of enterprise and prudence with the utmost coolness—enterprise to embrace favourable opportunities of buying and selling, and prudence and coolness to restrain from engaging in over-hazardous and ruinous speculations. In all his transactions, the man of business is understood to proceed upon a cool, inflexible principle of doing that which is most advantageous for himself, without fear or favour; because in commerce each party is supposed to be governed by motives of self-interest (always within the rules of honesty and propriety), and is under no obligation to deal from mere personal regard, or any kind of friendly

consideration. In commerce there is, strictly speaking, no friendship in the ordinary acceptation of the term. If there be friendship among the parties concerned, it is a thing aloof from business transactions—a matter of private arrangement—and is only to be regarded as such. On this account, even among the most intimate friends, there must be an exact mode of dealing, and the most accurate counting and reckoning.

The British, for several centuries, seem to have been endowed above all other nations with those qualities of mind which are suitable for the conducting of commerce on an enlarged and liberal scale. Their integrity, persevering industry, enterprise, prudence, and liberality of sentiment, have never been excelled. In patient industry they have been rivalled by the Dutch; but in point of enterprise and liberality that people have fallen far short of them, and their trade has languished accordingly. The British are pre-eminently a commercial as well as a manufacturing people. Taking them generally, they possess a spirit of restless industry, which renders them actually unhappy unless when busily engaged in some pursuit calculated to enrich them, or at least to produce for their families the means of a respectable subsistence. The Americans, who are but a branch of the same British stock, are equally if not more remarkable for this fervent spirit of industry; and though only set up as a separate nation within a comparatively recent period, and less distinguished for their integrity and prudence than the English, have already distanced many of those dignified European principalities and powers which first discovered and colonised their country. The French, the Germans, the Spaniards, the Portuguese, the Italians, and others, though each possessing a larger or smaller extent of manufactures and commerce, are obviously deficient in a national sense of the eager spirit of industry which is so characteristic of the people of Great Britain. Taken in the gross, they are too apt to addict themselves to amusement in preference to business. They delight in holidays, and will at any time leave their work to mingle in a dance or some kind of buffoonery in which an Englishman would be ashamed to appear. Scarcely one of the continental nations, moreover, has yet settled down under a well-conducted government appointed by the people. There indeed seems to be little which is settled amongst them. Some of the principal are yet at that stage of social life which was common in England about the reign of Henry VII.; others are not farther advanced than a period considerably earlier; and all have yet much to suffer and to learn before they attain that state of quietude and security to life and property, that condition of domestic comfort and national prosperity, which Great Britain, with all its imperfections, so amply enjoys.

COMMERCIAL TERMS AND TRANSACTIONS.

The following explanations of the principal terms used in commerce will illustrate the mode of conducting business transactions:—

*Firm.*—Every business, whether private or public, is conducted under a specified designation or title, called the name of the firm. This name may be that of a single individual to whom the business belongs, or of two or more individuals, or any title which it may be found advisable to adopt. Sometimes the name of a firm remains long after all who are indicated by it are dead. In such a case the business has passed into the hands of new proprietors, who, though legally responsible for its obligations, are not for some private reason inclined to change the old and well-known title of their firm. A particular firm or business-concern is sometimes personified in the term *house*—as, Such a house does a great deal of business, &c.

*Company.*—Two or more individuals engaged in one business constitute a company or copartnership, each individual being called a partner. Companies are of two kinds—private and public. A private company is organised by a private arrangement among the parties, each having certain duties to perform, and a certain share

in the concern. In companies of the private and common description no individual can leave the concern at his own pleasure, for by doing so he might seriously injure or embarrass his partners. He can withdraw only after giving a reasonable warning, by which time is allowed to wind up the concern, or place it in a condition to pay him back the capital which he has risked, or the profits which are his due. No partner, however, can transfer his share to another person, by which a new member would be introduced into the firm without the consent of the partners.

The profits of partnerships are divided according to a specified agreement or deed of copartnership. Generally in the case of partnerships of two or three persons, each receives the same share on the occasion of an annual division, but in other cases a partner may not be entitled to more than a fourth or sixth part of what another receives. The amount of capital which a partner invests in the concern, the service he can be to the business, and other circumstances, regulate the amount of his share. When each of two persons sinks the same capital, but one takes the whole of the trouble, then he on whom the trouble falls, who is called the active partner, is entitled to receive a stated sum in the form of salary over and above his share of profits. Whatever be the share which individual partners have in a concern, the whole are equally liable for the debts incurred by the company, because the public give credit only on the faith that the company generally is responsible. He who draws the smallest fraction of profit, failing the others, may be compelled to pay the whole debts. On this account every partner, on leaving a company, should be careful to advertise in the Gazette and newspapers that he no longer belongs to the firm of which he was a member; he is then responsible for no debts incurred subsequent to the announcement.

Public companies are very different: they consist of a large body of partners, or proprietors of shares, the aggregate amount of which forms a joint stock, and hence such associations are called *joint-stock companies*. They are public, from being constituted of all persons who choose to purchase shares, and these shares or rights of partnership are also publicly saleable at any time without the consent of the company. The value of a share in a joint-stock company is always the price which it will bring in the market; and this may be either greater or less, in any proportion, than the sum which its owner stands credited for in the stock of the company. Unless specially provided for in the fundamental deed of copartnership, every member of a joint-stock company is liable in his whole personal property or fortune for the debts of the concern. In some instances this liability is obviated by the provisions of an act of parliament, or parliamentary charter, establishing the company. Joint-stock companies are managed by directors appointed by the shareholders.

It is an axiom in commerce, that business is much better conducted by single individuals for their own behoof, than by companies of any kind; as respects joint-stock associations, they are only useful in very great concerns requiring enormous capital and involving serious risks of loss.

*Capital*.—What is now termed capital was in former times called *stock*. The capital of a merchant is strictly the amount of money which he embarks in his trade, or trades upon—that is, employs for buying goods, paying wages of servants, and liquidating all debts when due. When trading within the limits of his capital, business is done upon a secure footing; but if he proceed beyond these in any material degree, he is said to be *over-trading*, and is exposed to the chance of ruin or very serious embarrassment. Trading beyond the amount of available capital is, nevertheless, a prevailing error, and causes innumerable bankruptcies. With a comparatively small capital, a tradesman may carry on a large business by receiving payments shortly after making his outlays. By this means there is a rapid turning over of money, and small profits upon the various transactions speedily mount up to a large

revenue. For example, if a tradesman turn over his capital twelve times in the year, at each time receiving money for what he sells, he can afford to do business on a twelve times less profit than if he could turn over the same capital only once during the year. This leads us to a consideration of credit.

*Credit* in business is of the nature of a loan, and is founded on a confidence in the integrity of the person credited, or the borrower. An individual wishes to buy an article from a tradesman, but he has not money to pay for it, and requires to have it on credit, giving either a special or implied promise to pay its value at a future time. This is getting credit; and it is clear that the seller is a lender to the buyer. In all such cases the seller must be remunerated for making his loan. He cannot afford to sell on credit on the same favourable terms as for ready money; because if he were to receive the money when he sold the article, he could lay it out to some advantage, or turn it over with other portions of his capital. By taking credit the buyer deprives the seller of the opportunity of making this profit, and accordingly he must pay a higher price for the article, the price being increased in proportion to the length of credit. It very ordinarily happens that the seller himself has purchased the article on credit; but this only serves to increase its price to the consumer, and does not prevent the last seller from charging for the credit which he gives and the risk of ultimate payment which he runs. Credit for a short period is almost essential in all great transactions; but when going beyond fair and reasonable limits, it acts most perniciously on trade, by inducing heedless speculation, and causing an undue increase in the number of dealers with little or no capital. An excessive competition among these penniless adventurers is the consequence; each strives to undersell the other with the hope of getting money to meet his obligations, and thus vast quantities of goods are sometimes thrown upon the market below the original cost, greatly to the injury of the manufacturer and the regular trader. What are technically designated 'gluts in the market' frequently ensue from causes of this nature.

Defoe, who wrote upwards of a century ago, makes the following observations on credit and over-trading in his 'Complete English Tradesman':—'There are two things which may properly be called over-trading, and by both of which tradesmen are often overthrown: 1. Trading beyond their stock [or capital]; 2. Giving too large credit. A tradesman ought to consider and measure well the extent of his own strength; his stock of money and credit is properly his beginning; for credit is a stock as well as money. He that takes too much credit is really in as much danger as he that gives too much credit; and the danger lies particularly in this, if the tradesman overbuys himself—that is, buys faster than he can sell—buying upon credit, the payments perhaps become due too soon for him; the goods not being sold, he must answer the bills upon the strength of his proper stock—that is, pay for them out of his own cash; if that should not hold out, he is obliged to put off his bills after they are due, or suffer the impertinence of being dunned by the creditor, and perhaps by servants and apprentices and that with the usual indecencies of such kind of people. This impairs his credit, and if he comes to deal with the same merchant or clothier, or other tradesman again, he is treated like one that is but an indifferent paymaster; and though they may give him credit as before, yet depending that if he bargains for six months, he will take eight or nine in the payment, they consider it in the price, and use him accordingly; and this impairs his gain, so that loss of credit is indeed loss of money, and this weakens him both ways.

A tradesman, therefore, especially at his beginning, ought to be very wary of taking too much credit; it would be preferable to let slip the occasion of buying now and then a bargain to his advantage, for that is usually the temptation, than buying a greater quantity of goods than he can pay for, run into debt, and be in-

sulted, and at last ruined. Merchants and wholesale dealers, to put off their goods, are very apt to prompt young shopkeepers and young tradesmen to buy great quantities of goods, and take large credit at first; but it is a snare that many a young beginner has fallen into, and been ruined in the very bud: for if the young beginner does not find a vent for the quantity, he is undone; for at the time of payment the merchant expects his money, whether the goods are sold or not; and if he cannot pay, he is gone at once. The tradesman who buys warily, always pays surely, and every young beginner ought to buy cautiously. If he has money to pay, he need never fear goods to be had; the merchants' warehouses are always open, and he may supply himself upon all occasions, as he wants, and as his customers call. It certainly 'is not possible in a country where there is such an infinite extent of trade as we see managed in this kingdom, that either on one hand or another it can be carried on without a reciprocal credit both taken and given; but it is so nice an affair, that I am of opinion as many tradesmen break with giving too much credit as break with taking it. The danger indeed is mutual and very great. Whatever, then, the young tradesman omits, let him guard against both giving and taking too much credit.'

**Orders.**—An order is a request from one dealer to another to supply certain goods. An order, when in writing, should be plain, explicit, and contain no more words than are necessary to convey the sense in a simple, courteous manner. The same rule applies to all letters of business, which, by the practice of trade, are confined to their legitimate object. He that affects a rambling and bombastic style, and fills his letters with long harangues, compliments, and flourishes, should turn poet instead of tradesman, and set up for a wit, not a shopkeeper. A tradesman's letters should be plain, concise, and to the purpose; no quaint expressions, no book phrases; and yet they must be full and sufficient to express what he means, so as not to be doubtful, much less unintelligible. We can by no means approve of studied abbreviations, or leaving out needful conjunctive terms and pronouns in trading letters; as, for example, 'Have just received yours of the 11th,' &c.; which ought to be expressed as follows—'I have just received your communication of the 11th instant,' &c. The leaving out of pronouns and other words in a business letter gives it a mean appearance.

**Counting-house:** in French, *bureau*; in Dutch, *kantoor*.—The counting-house is the office in which a merchant's literary correspondence, book-keeping, and other business is conducted. The English merchant's counting-house is a model of neatness and regularity. Its furniture consists chiefly of desks for the clerks, and the books of the establishment, which are secured at night in an iron or fire-proof safe. Almost every different business requires a different set of books, but the mode of keeping them is generally the same. The usual set of books comprises a day-book, in which sales on credit are individually entered as they occur; an invoice-book, for the entry of purchases; a ledger, into which all these entries are engrossed in separate accounts; a memorandum-book, for entering miscellaneous transactions; a cash-book, in which every payment or receipt of money is regularly entered; a letter-book, into which all letters are copied before they are sent off; and a bill-book, for the entering of bills payable and receivable. In large concerns there are various other books—as foreign-ledger, town-ledger, country-ledger, &c. The art of book-keeping is simple. It requires only a competent knowledge of arithmetic, and skill in penmanship, with a little training in the method of entering and posting accounts. The strictest care and accuracy are desirable. It is an understood rule, that no book should show a blot or erasure; a leaf also should never on any account be torn out, whatever blotch or error it contains. The reason for this scrupulous care is, that a merchant's books should be a clear and faithful mirror of his transactions, and an evidence of his integrity. In the case of

misfortune in trade, or other circumstance, the books may be subjected to a rigid judicial examination, and the appearance of an erasure or torn-out leaf may lead to conjectures of an unpleasant nature and consequences. When an important error occurs in book-keeping, it is better to let it remain and write *error* below it, than to make a large erasure or to cut out the leaf.

From the books kept by a merchant, a condensed view of his affairs ought to be annually made up. This document contains an *inventory* or list of goods, money debts owing to the merchant, or other available property; also a contra list of all debts and other obligations due by the merchant. Both being balanced, the residue, whether for or against the merchant, is at once observable. Every person in trade, for at least his own satisfaction and government, should make up a *balance-sheet* of this nature annually.

**Bill of Parcels.**—An account or list of items of goods, given to their purchaser by the seller, or delivered along with the goods at the purchaser's house. Should a purchaser dispute the delivery of the goods, it is necessary to produce proof of the fact; when delivered to carriers, a receipt is usually given by subscribing the carrier's parcel-book.

**Invoice.**—A bill or account of goods, which is forwarded separately, announcing the date of their despatch, and the particular conveyance by which they are sent. If the seller fail to forward an invoice by post, and the goods be lost while on their way, the purchaser is not answerable. The careful sending of invoices forms an important duty of a merchant's clerk.

**Carriers.**—Persons who undertake to convey goods from one place to another, whether by land or water, are carriers; and the carrying-trade, as it is called, forms now a large and varied department of human industry. 'Carriers are bound to receive and carry the goods of all persons, for a reasonable hire or reward; to take proper care of them in their passage; to deliver them safely, and in the same condition as they were received (excepting only such losses as may arise from *the act of God or the king's enemies*): or, in default thereof, to make compensation to the owner for whatever loss or damage the goods may have received while in their custody that might have been prevented. Hence a carrier is liable, though he be robbed of the goods, or they be taken from him by irresistible force. On the same principle, a carrier has been held accountable for goods accidentally consumed by fire while in his warehouse.'—*M'Culloch*. Violent storms, tempests, and lightning, are considered to be 'the act of God,' or such as no human precaution could have averted, and no fraudulent intention could have produced.

**Bill of Lading.**—A formal acknowledgment or receipt given by sailing-masters for goods put on board their vessels, including a promise to deliver them safely, as marked and addressed, to their designed destination; always, however, excepting loss or injury by the act of God, the king's enemies, fire, or the dangers or accidents of the sea. This bill of lading is usually a printed form, filled up with writing, and concludes with the quaint and pious wish—'And so God send the good ship to her destined port in safety: amen.' A set of two bills of lading is furnished to the shipper of the goods; one of which he retains for his own satisfaction, and the other is forwarded by post, like an invoice, to the individual or company to whom the goods are sent. When the ship arrives at its destined port, this document can be employed to cause the captain of the vessel to deliver the goods therein mentioned.

A *Manifest* is a document containing a specific description of a ship, her cargo, and passengers. It is signed by the master at the place of lading.

**Drawback.**—A term used in reference to those duties of customs or Excise which are repaid by government on the exportation of the commodities on which they are levied. This repayment is made with a view to enable the exporter to sell his goods in the foreign market unburthened with duties. Before shipping goods upon which drawback is to be claimed, notice must be

**Debeniture.**—This is the name of a formal certificate employed to recover a certain amount of drawback of duties from the customhouse on goods exported. The exporter draws up and signs the certificate, the signature being attested by a magistrate; and being forwarded to the customhouse, it is compared with the return of the officer who has seen the goods packed and sealed. After a certain period has elapsed the duties are paid to the exporter. The meaning of this transaction is, that on exporting goods, any government duty that may have been imposed upon them is paid back to the exporter, so as to relieve the foreign or colonial receiver from the burthen of using taxed commodities. It also acts as a bounty on exportation.

The word 'debeniture' has another application: it signifies a certificate of mortgage or loan on railway or other public works. Debenitures of this class are documents briefly and simply expressed, conveying authority to the holder to seize the property impledged, on the event of the obligations of the deed not being fulfilled. Along with these debentures are given a sheet of separate orders to receive payment of interest at appointed terms. These orders being cut off for presentation for payment, are called *coupons*.

**Customs—Excise.**—The duties or taxes imposed upon goods entering or going out of the country are called *customs*, and those imposed upon goods at the period of their manufacture in the country are called *Excise duties*. Both form a prime element in the national revenue, and are levied by boards of customs and Excise, each having an extensive ramifications of subordinate functionaries, for the imposition and collection of the duties. A customhouse is established at every principal port. Nearly all customs and Excise duties must be paid at the time the goods are passed through the hands of the officers of either department, and fall in the first instance on the merchant and manufacturer. They, however, enhance the price of the commodities, and are therefore ultimately paid by the consumer. For the accommodation of merchants, the customhouses in the different chief ports possess large warehouses or depôts for goods, called *bonded warehouses*. Goods subject to duty may, on importation, be consigned to these depôts, where they are allowed to remain till the merchant finds it convenient to remove them, and pay the accustomed duties. Until removed, therefore, the commodities in bond can hardly be said to be imported into the country, being in the condition of goods still lying in a foreign port.

**Smuggling** is the common term for contraband trading, or importing goods without paying duty. 'This is a practice,' says an experienced commercialist, 'which can only be stopped by a moderate tariff. When duties are excessive, experience has shown that an illegal traffic will be created which no power or ingenuity can put down. The abolition of smuggling, by wise and moderate legislation, is desirable, moreover, on higher grounds. The moral influence of the law is impaired when it first tempts to its own violation, and then punishes; for a sympathy is thereby created in favour of the breakers of it.' At present, Great Britain pays upwards of half a million annually for the protection of her customs against contraband trading!

**Tariff, or tarif,** is the term applied to a table of the articles subject to customhouse and Excise duties, with their respective rates.

**Official and Declared Value.**—All goods exported are entered in the customhouse books as of so much *official value*. This value is quite illusive as respects the real value of the articles. The official valuation is according to an estimate of the date 1694, without reference to the alteration of prices since that period. Knowing the fixed official price, we may be able to estimate the exact quantities, but this is a matter which few private individuals understand. The *declared value* is the price announced by the exporters of the goods, and amounts to nothing more than a rough estimate; it

up reports of the export trade.

**Lloyd's.**—Lloyd is not the designation of any individual or of any company: it is a title used in reference to a set of subscription rooms, or coffee-house (originally kept by a person of the name of Lloyd), situated in the Royal Exchange buildings, London. One of the rooms at Lloyd's (for a historical account of which see 'Chambers's Journal,' No. 111, New Series) is devoted to subscribers who follow the profession of marine insurers, technically called *underwriters*, from their writing under, or subscribing to, certain obligations in deeds presented for their acceptance. When a person wishes to insure a ship, or goods in a ship, against damage or loss at sea, he offers the risk to these underwriters, and they are at liberty to accept it for a specified premium. The policy, or deed expressive of the insurance, is usually signed by more than one underwriter, so as to divide the risk. Lloyd's is not only a centre point in the metropolis for all sea-insurance business, but is the place to which every species of intelligence respecting shipping is forwarded from all parts of the world; and this information is exhibited publicly in one of the rooms for the inspection of all. The intelligence is for the most part sent by appointed agents, one part of whose duty consists in investigating the cause of damage to vessels, and taking charge of wrecked property, for behoof of the underwriters, whoever they may be. The lists made up and exhibited at Lloyd's furnish authentic information for the use of merchants and shippers of goods all over the United Kingdom.

**Vendue.**—This is a colonial phrase, used instead of *public auction*. To sell goods at vendue is to dispose of them at auction. The place of sale is sometimes called 'the Vendue.'

**Dutch Auction.**—In common auction, the highest bidder by competition is the purchaser; but according to the process of sale called Dutch Auction, there is a different mode of determining the successful bidder. According to this plan, the article is put up at a certain nominal price, which is gradually lowered, and the first who speaks and offers the sum mentioned by the auctioneer is at once knocked down as the purchaser. This is the fairest mode of auctioneering; it prevents competition, and the article brings its exact value—that which it is worth in the estimation of those present.

**Insolvency, Bankruptcy.**—When a person is not in circumstances to pay his debts in full, he is *insolvent*, which is nearly equivalent to being bankrupt: the term bankrupt, however, is more commonly applied to one who is legally announced or gazetted as being insolvent. The term bankrupt is derived from *banca*, a bench, and *ruptus*, broken; in allusion to the benches formerly used by the money-dealers in Italy, which were broken in case of their failure to pay their debts. The law prescribes a certain form of procedure in the case of commercial insolvency, which has the effect of deliberately investigating the cause of the misfortune, and relieving the bankrupt from all obligations, on yielding up his entire property. Only persons in trade are entitled to the benefit of this bankrupt law, all others being excluded; so that, in the event of their insolvency, they must submit to the common laws respecting debtors, which are in some respects very rigorous. A bankrupt who has received a discharge or certificate from a competent authority, being released from all pecuniary claims, may again enter business for his own behoof without any fear of molestation; but a debtor who has merely taken the benefit of the Insolvent Act in England, or process of *Cessio Bonorum* in Scotland, though immediately relieved from prison, and left at liberty to pursue any line of industry, the property he may accumulate is at all times liable to seizure by his former creditors.

A commission of bankruptcy in Scotland is entitled a *sequestration*, meaning that the property of the bankrupt is officially sequestered, or taken possession of, on

## MONEY.

behalf of his creditors. A payment of so much per pound by a bankrupt to his creditors, they agreeing to receive this sum in lieu of the full amount of his debts, is termed a *composition*; and when such a composition is made, and paid at different instalments, each instalment is spoken of as a *dividend*. The term dividend is also applied to the profits divided amongst the proprietors of joint-stock companies, and the like. The persons to whom the realisation, management, and distribution of the estate of a bankrupt are committed, are termed his *assignees*.

A *monopoly* is properly a privilege granted by license, conferring on an individual or company the sole right of purchasing and disposing of, making or using, a certain specified article. The term, however, is often used to denote the engrossing of commodities with the view of selling them at a high price. Monopolies granted by royal license were at one time frequent in England; but are now entirely abolished, with the exception of patents for inventions or improvements, and these exist only for a limited number of years.

*Price-current* is the technical term for a list showing the market prices of commodities.

## MONEY.

*Origin and Nature of Money.*—In a rude state of society, exchanges are made by bartering one article for another, according to some kind of understood value. 'But when the division of labour first began to take place,' says Smith, 'this power of exchanging must frequently have been very much clogged and embarrassed in its operations. One man, we shall suppose, has more of a certain commodity than he himself has occasion for, while another has less. The former, consequently, would be glad to dispose of, and the latter to purchase, a part of this superfluity. But if this latter should chance to have nothing that the former stands in need of, no exchange can be made between them. The butcher has more meat in his shop than he himself can consume, and the brewer and the baker would each of them be willing to purchase a part of it; but they have nothing to offer in exchange, except the different productions of their respective trades, and the butcher is already provided with all the bread and beer which he has immediate occasion for. No exchange can in this case be made between them. He cannot be their merchant, nor they his customers; and they are all of them thus mutually less serviceable to one another. In order to avoid the inconvenience of such situations, every prudent man in every period of society after the first establishment of the division of labour, must naturally have endeavoured to manage his affairs in such a manner as to have at all times by him, besides the peculiar produce of his own industry, a certain quantity of some one commodity or other, such as he imagined few people would be likely to refuse in exchange for the produce of their industry.'

Many different commodities, it is probable, were successively both thought of and employed for this purpose. In the rude ages of society, cattle are said to have been the common instrument of commerce; and though they must have been a most inconvenient one, yet in old times we find things were frequently valued according to the number of cattle which had been given in exchange for them. The armour of Diomedes, says Homer, cost only nine oxen; but that of Glaucus cost a hundred oxen. Salt is said to be the common instrument of commerce and exchanges in Abyssinia; a species of shells in some parts of the coast of India; dried cod at Newfoundland; tobacco in Virginia; sugar in some of our West India colonies; hides or dressed leather in some other countries; and there is at this day a village in Scotland where it is not uncommon, I am told, for a workman to carry nails instead of money to the baker's shop or the alehouse.

In all countries, however, men seem at last to have

been determined by irresistible reasons to give the preference for this employment to metals above every other commodity. Metals can not only be kept with as little loss as any other commodity, scarce anything being less perishable than they are, but they can likewise, without any loss, be divided into any number of parts, as by fusion those parts can easily be re-united again—a quality which no other equally durable commodities possess, and which, more than any other quality, renders them fit to be the instruments of commerce and circulation. The man who wanted to buy salt, for example, and had nothing but cattle to give in exchange for it, must have been obliged to buy salt to the value of a whole ox or a whole sheep at a time. He could seldom buy less than this, because what he was to give for it could seldom be divided without loss; and if he had a mind to buy more, he must, for the same reasons, have been obliged to buy double or triple the quantity—the value, to wit, of two or three oxen, or of two or three sheep. If, on the contrary, instead of sheep or oxen, he had metals to give in exchange for it, he could easily proportion the quantity of the metal to the precise quantity of the commodity which he had immediate occasion for.

Different metals have been made use of by different nations for this purpose. Iron was the common instrument of commerce among the ancient Spartans; copper among the ancient Romans; and gold and silver among all rich and commercial nations.

Those metals seem originally to have been made use of for this purpose in rude bars, without any stamp or coinage. Thus we are told by Pliny, upon the authority of Timæus, an ancient historian, that till the time of Servius Tullius the Romans had no coined money, but made use of unstamped bars of copper to purchase whatever they had occasion for. These rude bars, therefore, performed at this time the function of money.

The use of metals in this rude state was attended with two very considerable inconveniences: first, with the trouble of weighing; and secondly, with that of assaying them. In the precious metals, where a small difference in the quantity makes a great difference in the value, even the business of weighing with proper exactness requires at least very accurate weights and scales. The weighing of gold, in particular, is an operation of some nicety. In the coarser metals, indeed, where a small error would be of little consequence, less accuracy would no doubt be necessary. Yet we should find it excessively troublesome if, every time a poor man had occasion either to buy or sell a farthing's worth of goods, he was obliged to weigh the farthing. The operation of assaying is still more difficult, still more tedious; and unless a part of the metal is fairly melted in the crucible, with proper dissolvents, any conclusion that can be drawn from it is extremely uncertain. Before the institution of coined money, however, unless they went through this tedious and difficult operation, people must always have been liable to the grossest frauds and impositions; and instead of a pound weight of pure silver or pure copper, might receive in exchange for their goods an adulterated composition of the coarsest and cheapest materials, which had, however, in their outward appearance been made to resemble those metals. To prevent such abuses, to facilitate exchanges, and thereby to encourage all sorts of industry and commerce, it has been found necessary, in all countries that have made any considerable advances toward improvement, to affix a public stamp upon certain quantities of such particular metals as were in those countries commonly made use of to purchase goods. Hence the origin of *coined money*, and of those public offices called mints—institutions exactly of the same nature with those of the aulnagers and stampmasters of woollen and linen cloth. All of them are equally meant to ascertain, by means of a public stamp, the quantity and uniform goodness of those different commodities when brought to market.—*Smith's Wealth of Nations*, book i. chap. 4.

money is only an article which can be conveniently used in exchanging. In itself, or as relates to its own intrinsic qualities, it is a thing but of small value. Gold and silver, or the precious metals, of which money is usually made, are chiefly brought from the mines of South America, and are commercially valued according to the cost of their production and their supply and demand, as is the case with every other object in trade. If an over-abundance of any of these metals be easily obtained, and the demand be not increased, the value is immediately lowered; and if the supply is obtained with difficulty, while the demand remains steady, or is increased, the value is heightened. It cannot be too strongly impressed on the mind of the reader, that money is but a metallic representative of something which has been given for it. To a misunderstanding regarding this apparently very simple circumstance, much human misery may be attributed. It has too often been the feeling of communities, that if they possessed gold they possessed riches, and not a mere article for facilitating commerce—an article which, from its uses in this respect, is itself a commodity. The most startling illustration of this fallacy is to be found in the history of Spain. Before the working of the gold mines in their American possessions, the Spaniards were a rich and prosperous commercial people; but when they began to find gold, they thought they had got at their hand that for which they formerly laboured, and that, like a poor industrious man who has unexpectedly succeeded to an estate, they need now work no longer. To prevent their riches from disappearing, the law prohibited the exportation of the precious metals, and thus effectually shut the door against the only way in which they could be made sources of wealth—exportation as an article of commerce. In that view, and in that alone, was there any advantage in the possession of gold; and even had it been employed in the most advantageous manner, it would not have been so profitable as many other means of employing capital and labour; for, as already remarked, the peculiarity which makes gold so useful as a measure of value is, that the labour usually expended in producing it bears so constant a ratio to the quantity realised, that but small profits are made from its production.

The manner in which the Spaniards became acquainted with the treasures of South America tended to nourish the delusion. They found a considerable quantity of gold in the possession of the natives, which they speedily seized. They found also native gold in the streams. Thus, by an accidental circumstance, such as that of finding a hidden treasure, they became possessed of money without working for it. They did not reflect that if this lasted, gold would cease to be the representative of value which it was, and would be of no further service in commerce than as an extremely beautiful material for manufactures, which would fluctuate in value with the tide of fashion. When they could procure the mineral only by the result of hard labour, they still had the same preposterous feeling that they were possessed, not of the means of making wealth, but of wealth itself; and dearly did they pay the penalty. While starvation desolated the land, and the highest grandees could not command so much of the produce of ordinary commercial industry as a glass window, every wretched dwelling glittered with mountains of plate.

Gold, it is necessary to repeat, is simply a commodity—a commodity which we import: and if we can export it profitably, why not do so? If the country in question will take nothing from us but gold, then it is either worth our while to buy gold for the purpose of sending to it, or it is not. If it is not worth while, then the trade will not be carried on at all. If it is worth while, then the trade is on the whole a profitable one. If we import sugar from the Spanish settlement of Manilla, and export it to Germany, this is called 'the carrying-trade,' and quite correctly; but it seems to be thought that if we import gold from South America, we must

It is commonly said that we pay in our own manufactures. Now paying in gold is, after all, indirectly paying with our own manufactures, for (except the comparatively trifling quantity that may have been taken in war) there is not an ounce of bullion in the country that has not been obtained in exchange for some article produced either by our manufacturing or agricultural industry. Let him who doubts this position, try if he can discover any other method by which gold can have found its way to this country.

**Coined Money.**—Gold and silver, as we have said, are chiefly brought from the mines of South America. They are generally imported in the form of bars, and in this rude state are commercially named *bullion*. The price of bullion in the market is liable to fluctuations, according to the cost of production, the supply, and the demand. However, the variation is never very great, and has little sensible effect on the coinage. It is customary to estimate the purity of gold by an imaginary standard of 24 carats. The carat is a small weight of universal use, containing 4 grains. It originated from the carat or kaura, a small bean, used by the Abyssinians for weighing gold. Diamonds are also weighed by it. If in a piece of gold weighing 24 carats there be 1.24th of alloy, then the piece is 1 below the standard. What is called jewellers' gold is seldom purer than 20 fine to 4 of alloy—the alloy being usually silver, but sometimes copper, which gives a deeper red tinge to the metal. Perfectly pure gold is never seen either in trinkets or coins, for it is too ductile, and for that and other reasons requires a certain quantity of alloy. Sovereigns, and other modern English gold coins, contain 1.12th of alloy; but this twelfth is not reckoned as gold in point of value. At present the gold coin of Great Britain is issued at very nearly its precise market value as bullion. A pound weight of gold, of 22 carats' fineness, produces coins to the amount of £46, 14s. 6d., which is about the price at which bullion sells for in the market. Thus the gold of our currency is coined free of expense, or at the rate of £3, 17s. 10½d. per ounce—the weight of a sovereign being 5 dwt. 3.274 grains. In coining silver, government is allowed by the act 56 Geo. III. a profit or seignorage of about 6 per cent.; the pound weight of silver, which should produce 62s., being coined into 66s.—that is, at the rate of 6s. 6d. per ounce. Our silver coins being therefore of a little less real value than the sums they represent, they are not liable to be melted down by silversmiths for the manufacture of articles in their trade.

Till the year 1816, on the occasion of a new coinage, the silver shilling was the standard of money, though, for convenience, the pound of 20s. was the principal sum named in commercial transactions. The act 56 Geo. III. rendered gold the principal standard, and made silver subsidiary to it; since which period no more than 40s. are a legal tender; that is to say, no one is bound to accept of more than 40s. in silver in payment of any debt or demand. The legal tender above 40s. is in sovereigns; but in point of fact an order on the Bank of England is considered equivalent.

At present gold is issued in sovereigns (of twenty shillings) and half-sovereigns: the issue of double sovereigns is also authorised, but none are in circulation. Silver is issued in crowns (of five shillings), half-crowns, shillings (of twelve pence), sixpences, and groats, or fourpences; a few pieces for 3d., 2d., and 1d., called *Maundy Money*, are also made for the purpose of distribution as alms by the sovereign, but they are not in general circulation.

The copper coinage, consisting of pennies, halfpence, and farthings, is issued from the mint at the rate of £224 per ton, being more than 100 per cent. above its market value; in other words, a penny-piece is intrinsically worth no more than a halfpenny. Formerly, the pieces usually known as old pennies were larger; but in consequence of a rise in the value of copper

## MONEY.

in 1806, it has since been thought advisable to adopt the rate above mentioned.

The coined money of Great Britain is the most elegantly executed, and among the purest in the world. The greater part of the continental coinage is poorly executed, and basely alloyed. In Holland, and most of the German states, the coins legally current as silver money are apparently one-third brass, and resemble the counterfeit shillings and sixpences of a former period in England. In France and Belgium, the new gold and silver coins are handsome, and so likewise are the large gold and silver pieces of Prussia. The coins and medals executed by direction of Napoleon in France are in a high style of art.

Money of the current and standard coinage is frequently signified by the term *sterling*, as 'one pound sterling,' &c. With respect to the origin of the word *sterling* there are three opinions: the first is, that it is derived from Stirling Castle; and that Edward I. having penetrated so far into Scotland, caused a coin to be struck there, which he called *Sterling*; the second opinion derives it from the figure of a bird called *sterling*, which appears about the cross in the ancient arms of England: the third most probably assigns its true origin, by deducing it from *Esterling*; for in the time of Henry III. it is called *Moneta Esterlingorum*, the money of the *Esterlings*, or people of the East, who came hither to refine the silver of which it was made; and hence it was valued more than any other coin, on account of the purity of its substance. The denomination of the weights and their parts is of the Saxon or *Esterling* tongue—as pound, shilling, penny, and farthing, which are so called in their language to the present day. The term *sterling* is now disused in England in all ordinary transactions, but is still used in Scotland, to distinguish sums from the ancient money of the country, as referred to in old deeds and notices of pecuniary transactions. The old Scots money, previous to the Union of 1707, was in pounds, shillings, and pence, but these were only a twelfth of the value of sterling money of the same denomination: thus a pound Scots was only twenty pence sterling. The word *sterling* is also in use in the colonies, to distinguish the legal standard of Great Britain from the currency money in these places.

The following is a short explanation of the origin of the principal terms used in reference to coined money. The word *money* is from the temple of Juno *Moneta*, in which money was first coined by the ancients. *Pecuniary* is from *pecus*, a flock—flocks and herds of animals being originally equivalent to money, or things constituting wealth. *Cash*, in commerce, signifies ready money, or actual coin paid on the instant, and is from the French word *caisse*, a coffer or chest in which money is kept. *Pound* never was a coin; the term was originally employed to signify a pound weight of silver, but afterwards it was applied to mean 20s. in tale, or by counting. *Guinea* took its name from the coast of Guinea in Africa, whence the gold for it was originally brought; at first, the piece was current at 20s., afterwards it was equal to 21s. 6d., and finally settled at 21s. In the present day the guinea is not coined, and the term only remains to indicate 21s. Honorary fees and gifts are still usually reckoned in guineas, though paid in other money. *Shilling* and *penny* are both from Saxon words: the penny was first coined in silver. *Groat* was a name given to silver pieces equal to four pennies in value, coined by Edward III.: the word *groats* is a corruption of *grosses*, or great pieces, and was given to distinguish this larger coinage from pennies or small coins. *Farthing* is a corruption of *fourthing*, or the fourth part of a penny.

The coining of money forms one of the exclusive privileges of the crown, and the counterfeiting of it constituted formerly the offence of high treason. At present the integrity of the coinage is guarded by a recent act, under which persons counterfeiting or impairing it are liable to imprisonment and transportation. Penalties are also imposed on those uttering false coins

—having three or more such pieces in their possession with intent to put off the same—and on those making, mending, or having in possession any coining tools. The loss on coins by ordinary tear and wear has been variously estimated. According to experiments made at the Mint in 1835, the waste per cent. per annum appears to be—on sovereigns, from 9d. to 10½d.; on half-sovereigns, from 1s. to 1s. 6½d.; on half-crowns, from 2s. to 3s.; on shillings, from 2s. 3d. to 6s.; and on sixpences, from 6s. to 8s. These results—making allowance for the greater use of some coins than others—confirm the general estimate that standard gold possesses about four times the durability of silver.

A currency of gold is, therefore, the most secure and permanent, and the pieces are received for their proper value in all countries. But notwithstanding these advantages, a metallic currency alone is quite unsuitable in highly-commercial communities. There is no adequate importation of the precious metals at the ordinary value to supply material for a purely metallic currency; and if it were possible to provide a sufficient supply, the inconvenience and risk of loss to individuals from using coins only in all mercantile transactions would be too great to be patiently borne. A heavy loss would also be incurred annually by government from tear and wear, which it would be impolitic to avert by imposing a proportionate seignorage. In these and other points of view, a currency of metal only would be exceedingly unsuitable to the existing condition of society and commerce in Britain. Something more convenient requires to be employed as a medium of exchange and representative of the enormous sums which are daily transferred from one to another all over the country.

*Paper Money*.—The deficiencies of a metallic currency are compensated by the use of paper money. Paper money is in the form of small pieces of paper, each purporting to be an obligation or promise to pay a certain sum which is specified upon it. Whether passing by the name of a bank-note, a promissory-note, or bill of exchange, the principle on which it is issued is the same—an express obligation on the issuer to pay the specified sum in coined money on demand, or at a certain date which is mentioned. The notes of this kind issued by a bank pass from hand to hand, any holder having it in his power at any time to demand fulfilment of the obligation from the bank; but in the case of a bill of exchange, which is a promise by a private party, it is presentable for payment only at a specified period. Bank-notes and bills together constitute the paper currency of the country, and are of prodigious use in carrying on commercial transactions.

*Bills of Exchange* were first used for the purpose of settling pecuniary transactions between individuals at a distance from each other, and were therefore convenient expedients to avoid the risk of sending actual money to a creditor. This may be explained as follows:—If A, a merchant in London, have a debtor B and a creditor C, both in Paris, instead of sending money to C, and getting money sent to him by B, he may give C an order on B to pay the debt over at once to him. This is a bill of exchange in its simplest form. Suppose, however, that A has a creditor in Paris, but no debtor, while his neighbour E has a debtor, but no creditor; A may pay the money to E which the French debtor owes him, and obtain from him an order on his debtor to pay A's French creditor. This order he will be said to purchase. It will be an accommodation to him or to the other party, according to circumstances. In the complicated arrangements of modern commerce the individual debtors and creditors are lost sight of. If a person has a sum to transmit to another country by such an order, the rate at which he will obtain it will depend on the pecuniary relations of the two places taken in the main. If there is more money payable at the moment by people in London to people in Paris than there is payable by those in Paris to those in London, there will be a demand for orders on Paris, and a premium will be payable for the accom-

give such drafts than there are in want of them, and those who dispose of them must do so at a discount. The rate of exchange is from this circumstance said to be in favour of Paris. The premium in the one case, and the discount in the other, will be measured by the balance due by London to Paris over what is due by Paris to London; and the principal sum to be met by the rate of exchange will be the expense of transmitting that balance in specie, unless the accounts can be adjusted by bringing transactions with some other community into the circle.

We may vary this explanation of the principle of exchange as follows:—Great Britain, like every other country, is exposed to a drainage of its metallic currency, by the balance of trade falling against it. As long as our exports are equal to our imports they will balance each other; the bills drawn in England against foreign countries will be balanced by bills drawn in foreign countries against England. In this state of things the exchange is said to be at *par*, or even. If our exports exceed our imports, then foreigners must send actual money for the overplus, because they have not occasion to remit bills for the amount. If our imports exceed our exports, we must in the same manner remit the overplus in actual money. Thus a dearth and scarcity of corn in England will cause a drainage of the precious metals, because our imports of that article rise to a large amount, or much beyond the value of the manufactured goods exported. The exchange is then said to be against England.

The multifarious transactions taking place between merchants in Britain and America cause an incessant process of payment by the intervention of bills of exchange, many thousands of pounds being paid away daily in their accounts with each other without the aid of any metallic money, except perhaps a few coins for small odd sums.

Here is a common form of drawing a bill of exchange:—

£100. LONDON, 5th August 1840.  
Three months after date, pay to me or my order the sum of one hundred pounds, value received.  
To Mr THOMAS STYLES, Merchant, JOHN NOKES.  
Cripplegate, London.

The bill being drawn in this form, Mr Styles accepts it, by writing his name either below that of Mr Nokes, or across the face of the writing. Mr Nokes, who is called the *drawer*, now endorses the bill, by writing his name on the back of it, and thus the bill becomes *negotiable paper*. It may be paid away to a third party; and he endorsing it below Nokes's name, may pay it away to a fourth; and he endorsing it in the same manner, may pay it away to a fifth; and so on. Thus the bill may pass from hand to hand, on each occasion liquidating a debt of £100, till the day of payment by the original acceptor arrives, when it is duly presented by the last holder. Instead of running this course, the bill may at any period be *discounted* by a bill-broker or banker. The discounting of a bill consists in giving the money for it, less a certain sum for *interest*. Interest is a charge for the loan of money, and is ordinarily reckoned by *per cent*. Thus 5 per cent. (or centum) per annum signifies a charge of £5 for every £100 for one year, which is equal to a shilling for each pound. Five per cent. is the highest legal interest chargeable in the United Kingdom on all money lent in ordinary circumstances; but for discounting bills or promissory-notes, a larger per centage may now be legally taken. When a bill for £100 for three months (or fourth part of a year) is discounted at 5 per cent. interest, a charge equal to the fourth part of £5 is made by the discounter, and this is his profit for the loan of the money for that period. Interest for a single day on any sum may be easily calculated by a rule in arithmetic; but merchants and bankers, for the sake of expedition and

presentable for payment till the third day after that which is specified for them to fall due. The three days allowed are called the *days of grace*. Thus a bill drawn on the 5th of August, at three months, is not legally due till noon of the 8th of November. In some countries the period of grace is much longer than three days.

Bills of exchange are occasionally drawn in the form of promissory-notes; as, for example:—

£100. LONDON, 5th August 1840.  
Three months after date, I promise to pay to Mr John Nokes, or order, the sum of one hundred pounds, value received.  
THOMAS STYLES.

When in this form, no signature is written across the front of the document—it is only endorsed by the creditor. Promissory-notes are in every respect liable to the same regulations as bills. Both promissory-notes and bills must be written on stamps of the proper price; if on stamps of an inferior value, they are not negotiable, and cannot be protested. The protesting of a bill is simply the marking of a notary-public that it has not been duly paid on presentation; which marking, or *noting*, forms the warrant for the issuing of legal diligence by the competent authorities. If not protested on the day it has fallen due, this step cannot be taken afterwards, and the bill remains a mere evidence of the debt, to be produced in the course of a regular and perhaps tedious prosecution. Men in business are careful to present their bills for payment on the exact day they become due. When the acceptor of a bill fails to pay the amount, the holder can fall back for payment on any of the endorsers, or the drawer.

Bills are sometimes drawn at *sight*, or so many days after sight; for example:—

£50. LONDON, 5th August 1840.  
Ten days after sight, pay me or my order the sum of fifty pounds, value received.  
To Mr ISAAC WALTERS, JOHN JENKINS.  
Cheapside.

A bill of this kind is usually drawn by a person at a distance from his debtor, and on writing it out and endorsing it, he transmits it to an agent (or probably a creditor of his own) in the town in which the debtor resides. The agent having received it, hastens with it to the debtor to be *sighted*, which consists in the debtor, as, for instance, the above Mr Walters, accepting it, by signing his name, and marking the day on which he has done so. The bill is now a negotiable instrument, and on the third day after the day specified it is presentable for payment. This may be called a convenient way of getting ready money or prompt payment of any sum from a debtor. It is very common to draw *foreign bills of exchange* at so many days after sight. These bills are of precisely the same nature as inland or home bills of exchange; but for the sake of security in transmission, they are drawn in sets of three. The following is a common form:—

£100. MONTREAL, 18th June 1840.  
Sixty days after sight, pay this my first bill of exchange (second and third of the same tenor and amount being unpaid), for the sum of one hundred pounds sterling, value received.  
To Messrs BROWN and JONES, SAMUEL ROBERTSON.  
Merchants, Bristol.

This bill being endorsed by Mr Robertson, is transmitted to England (probably in liquidation of a debt of the same amount), and is presented to Messrs Brown and Jones to be sighted, and is afterwards presented to them for payment accordingly. The agent or individual to whom it is sent, receives by the next packet the second bill of the same tenor. Should the first have been lost by shipwreck, this second is available; but otherwise it is of no use, and may be destroyed. The third bill of the same tenor is retained by the

## BANKS.

drawer till he learn whether the first or second have been received; if both have been lost, it is transmitted. Bills of this description are rarely sent by the actual drawer. They are usually paid away or sold on the spot to another party, who transmits them to a creditor of his own, and he negotiates the payment. The abundance or scarcity of foreign bills of exchange affects their price. If many merchants be in quest of bills of this nature to send abroad, and there be few having them to dispose of, they rise to a premium; in other words, a merchant in New York may give £105 for a bill for £100 payable in England. If, on the contrary, there be many bills and few buyers, they will be disposed of at a discount. These differences constitute what is called the *difference of exchange*.

Bills of exchange serve three useful purposes in commerce. 1. A bill puts a debt in a tangible form: for example, instead of leaving a debt of £100 to be paid at an indefinite period, so as to protract its settlement, let it be put in the shape of a promise to pay, and the creditor becomes satisfied that he now possesses the power to compel payment at a certain and not very distant period. 2. A bill is a negotiable instrument. If the parties be trustworthy, it may be discounted for cash; and thus, while the creditor will receive his money, less a trifle for discount, the debtor is left unmolested till the final day of payment. 3. A bill is a convenient representative of money, which may be sent from place to place in a letter, and if accidentally lost, its payment may be stopped, and a new bill forwarded to the proper destination.

The *currency or money* of the United Kingdom is about £26,000,000 of gold and silver coin, and £32,000,000 of bank-notes, chiefly of the value of five and ten pounds—total, £58,000,000. As nearly all large payments, however, are made by bills of exchange and drafts on bankers, there is an enormously large currency of that kind. It has been calculated that the amount of bills, promissory-notes, and bankers' drafts in circulation at any one time cannot be much less than £122,000,000. The centre of all the great money transactions of the British Empire is London, in which is situated the Bank of England, or principal banking institution. The amount of foreign and inland bills of exchange and drafts payable in London daily, is estimated at £4,000,000. In Scotland, which is justly celebrated for its well-conducted banking institutions, the money currency is chiefly one-pound bank-notes and silver. On the 7th of October 1848, the note circulation of the United Kingdom was as follows:—Bank of England, £17,505,718; private banks, £3,681,544; joint-stock banks, £2,666,749; Scotland, £3,136,516; Ireland, £4,506,421. The money coined in 1847 consisted of 110,400 lbs. gold, yielding £5,158,440; of 38,100 lbs. silver, yielding £125,780; and of 40 tons copper, yielding £4960 sterling.

## BANKS.

*Origin of Banks.*—The term *bank*, in reference to commerce, signifies a place of deposit of money, and is derived from the Italian word *banco*, a seat or bench, the first custodiers and dealers in money in Italy having been Jews, who sat on benches in the market-places of the principal towns. It is worthy of remark, that in the infancy of almost all modern civilised nations, the earliest money-dealers were Jews, and in the present day persons of that nation are the chief commercial negotiators in barbarous countries. Their acute intelligence, patient industry, disregard of local attachments, and kindred qualities, have in all ages fitted the Jewish people for this course of life.

About the reign of Charles I., Jews and goldsmiths, to whom valuable property had been assigned for safe custody, began to exercise the profession of bankers and money-dealers in England; but till a much later period there were several eminent bankers in London who still kept goldsmiths' shops.

On the continent of Europe regular banking commenced much earlier than in this country. The Bank of Venice was established as early as 1171, the Bank of Amsterdam was begun in 1609, and that of Hamburg in 1619. Regular banking establishments were formed in England and Scotland shortly after the Revolution. The Bank of England began in 1694, and the Bank of Scotland in 1695, since which period banks of various characters have been instituted in all the principal towns in the United Kingdom.

*Business of Banking.*—A bank is a commercial institution, established and conducted by private individuals for their own behoof, or by joint companies. Like a merchant's counting-house, it consists of various officials—a manager, cashier, clerks, &c. including tellers, or persons for receiving and paying out the money. Banks are usually reckoned to be of two kinds—banks of *deposit*, and banks of *issue*. By deposit it is meant that the bank takes charge of deposits of cash, which it is ready to restore on demand. Some banks of this nature allow interest on the sums received, and others do not do so; all, however, of necessity, make use of the money so deposited, by lending it out at a certain rate of interest, and thus compensate themselves for their trouble. The loans are most commonly in the form of discounts of bills, and occasionally advances on heritable property, or other securities. Banks of issue transact all the ordinary business of banks of deposit, and, in addition, issue notes of their own instead of actual cash or the notes of others. Almost all banks in this country are banks both of deposit and issue; they at least issue notes as far as the law allows them, which is to the extent of notes of £5 in value and upwards. The only banks permitted to issue below £5 are those in Scotland, for which a peculiar law exists.

Although banks are thus at liberty to issue notes to any extent, it is not to be supposed that they do so without a certain degree of restraint. The expense of manufacturing notes, notwithstanding that each requires a stamp, is a comparatively small check; the main restraint on over-issuing consists in the obligation to pay the sum, which the note expresses, on demand. When, therefore, a banker discounts a bill for £100, and gives out one hundred notes of £1 each, he encounters the risk of having these notes returned upon him, and a demand made for them in cash within the compass of a day or two thereafter. This risk is increased by the practice among bankers of never issuing the notes of others. They are anxious enough to push forth on a safe principle their own paper; but when they receive deposits or payments in the paper of another bank, they use all convenient speed in demanding cash from that bank in exchange for its notes. The notes of any given bank being received purely on a principle of good faith or credit, it is of great importance that the bank should do nothing to incur the suspicion of being incapable of retiring its notes. When any suspicion of this nature arises, the public, who are ignorant probably of the true circumstances, rush to the bank for gold in exchange for its notes. This kind of panic is called a *run*. Bankers are always naturally anxious to issue their notes to as great an extent as is consistent with safety to the institution. The measure of this safety is the extent of capital at command to liquidate demands for cash. To accommodate the amount of this capital to the probable necessities of the case, is the point in banking for which the greatest skill is required, because if much capital is kept lying useless in the coffers of the bank, there is a loss of interest which may be ruinous; whereas if too little is retained, a sudden run might utterly destroy the credit of the concern. When banking is managed with prudence, there is a certain amount of money kept at interest in the funds or government securities, upon which, if need be, an order is given. Thus a safety fund is established, whereon to fall back in case of emergency. A share of the subscribed and paid-in capital of the shareholders of the bank forms this safety fund; and it may be taken as a general rule, that where a bank is provided with

no such security, but issues notes on the faith of the fund it may chance to have on hand, then that bank is trading on a principle alike dangerous to itself and the public. A banker who unites enterprise with prudence takes every available means to extend the circulation of his notes in as minute and distant channels as possible; for as long as a note is out, an interest is being received for the capital which it represents. In other words, when a pound note is out, it represents a sovereign which has been deposited or given for it, and which sovereign is employed in a fund in some manner of way at interest, for the advantage of the banker.

On considering the various operations connected with banking, it will be found that, independently of the impulse and elasticity created by the facilities given to commerce, the direct and primary effect of them is the employment of waste money. A bank gathers, as it were, the money of a district into its hands, and allowing each man to use as much of his own share as he requires at the time, keeps the remainder likewise in employment, which would not have been the case had it remained in its owner's hands.

The rapidity with which all kinds of payments are made, and therefore the frequency with which money can be used, through the instrumentality of banks, form the most striking feature. In a bank office the same sum of money will have been made the means of paying its amount a dozen of times over in a day without being once uplifted. A, who is due B £100, gives a cheque for the sum, which will make it stand in his name instead of A's. B gives a similar cheque to C; C to D; and so on. 'The transfer of lodgments,' says Mr Gilbert, 'is extensively practised in our own times. If two persons, who have an account in the same bank, have business transactions with each other, the debtor will pay the creditor by a cheque upon the bank. The creditor will have this cheque placed to his credit. The amount of money in the bank remains the same; but a certain portion is transferred into a different name in the banker's books. The cheque given by the debtor is an authority from the debtor to the banker to make this transfer. Here the payment between the creditor and debtor is made without any employment of money. No money passes by one to the other: no money is paid out or received by the banker. Thus it is that banks of deposit economise the use of the circulating medium, and enable a large amount of transactions to be settled with a small amount of money. The money thus liberated is employed by the banker in making advances, by discount or otherwise, to his customers. Hence the principle of transfers gives additional efficacy to the deposit system, and increases the productive capital of the country. It matters not whether the two parties, who have dealings with each other, keep their accounts with the same banker or with different bankers; for as the banks exchange their cheques with each other at the clearing-house, the effect as regards the public is the same.'

London, in which the government funds are managed, and where all the great pecuniary transactions of the empire may be said to centre, furnishes a remarkable instance of the economising of money by the interchange of cheques or drafts among bankers. Each banking house in the metropolis sends daily the drafts it has received on other banking institutions to a place of common resort, called the clearing-house. Here a clerk from each bank attends and exchanges drafts. It is understood that the accounts balanced every day at this clearing-house amount to £8,000,000 sterling, the settlement being effected by the intervention of only about £250,000 in notes and cash.

*Bank of England.*—This institution, which is the largest and most important banking establishment in the world, was projected by William Paterson, a Scotchman, and received its charter of incorporation July 27, 1694. It was constituted as a joint-stock association, with a capital of £1,200,000, which sum was lent at

interest to the government of William and Mary, at the time in a state of embarrassment. At its very outset, therefore, the Bank of England was a mere engine of government; and in a lesser or greater degree it has enjoyed this character through all the stages of its subsequent history. According to its charter, the management is committed to a governor, lieutenant-governor, and twenty-four directors, elected by stockholders who have held £500 of stock for six months previous to the election. A director is required to hold £2000, a deputy-governor £3000, a governor £4000, of the capital stock. At first the charter of the Bank was for only eleven years; but in consequence of the great services of the institution to government, its charter has been at various times renewed. The original stock of £1,200,000 has been augmented at different times, till in 1816 it reached £14,553,000 upon which the stockholders drew dividends. The profits of the Bank arise principally from traffic in bullion, discounting of bills, interest on mortgages, allowance for managing the public debt, &c.

The net profit of the Bank in 1852, out of which interest was paid on the capital stock, was £1,189,627. The interest paid to stockholders has wavered from 5 to 10 per cent. per annum, but has more generally been about 8 per cent. The Bank has besides, at different times, made dividends under the name of *bonuses*. A bonus is a sum of money derived from the division of a fund, which has been suffered to accumulate or remain for use, in case of an emergency. The emergency being past, the fund is divided. The bonuses of the Bank of England have varied during the current century from 10 to 5 per cent.

The Bank of England is situated in a central part of London, adjoining the Royal Exchange. It is an extensive structure with interior courts, the whole covering an area of about eight acres of ground. Within the limits of the Bank are conducted, on an extensive and perfect scale of art, the various processes of printing notes and other documents for the establishment; and in the fire-proof vaults beneath is the repository of bullion, or bars of gold and silver and coined money, constituting the substantial stock of capital for the time being. The number of clerks, porters, and other officials employed in the establishment was lately about 900.

The Bank of England trades not only on its paid-up capital, but on the capital confided to it in the form of deposits, and usually called its *liabilities*. This is perfectly legitimate, and consistent with the true principles of banking, it being only necessary to take care that the institution always leaves itself a sufficient fund from which to satisfy all demands. The issue of notes by the Bank is understood to be somewhat in accordance with the amount of its deposits; but this is necessarily dependent on various contingencies in public affairs. The leading feature in the character of the institution is the circumstance of its acting as the banking-house for the government. All the money drawn in the form of taxes or otherwise for the public service is assigned to the Bank, while all drafts for the public service are likewise made from it. In carrying on this branch of its business, the Bank allows the government to overdraw its account—that is, to take a loan of cash to a certain amount. The money so lent was some time ago upwards of £14,000,000, which parliament made a provision to reduce and finally pay off. The important services rendered to the government have in past times secured to the Bank most valuable privileges, amounting almost to a monopoly of the business in money. In 1797, when the Bank found itself unable to meet a run made upon it for gold for its notes, the government of that day summarily protected it from bankruptcy by issuing an order that Bank of England notes should be considered a legal tender; consequently the holders of notes at the time were, by force of law, refused their value in cash. This extraordinary state of affairs, with various modifications, lasted till 1821, when cash payments were resumed. Meanwhile the notes of the Bank, from not being representatives of specie, were

## BANKS.

considerably depreciated in nominal value: so great was the depreciation at one time, that four-pound notes would have been given in exchange for three guineas. It has been frequently represented as a serious hardship, that debts contracted during this prevalence of a depreciated currency have had to be paid in a currency of full value; for by this means the creditor receives perhaps a third more money than the actual value of the original sum owing. The Bank of England manages the business of the national debt at an office within its precincts; for which service to the state it is paid a per-centage, which at present amounts to upwards of £91,000 annually.

*Joint-Stock Banks in England.*—A parliamentary return was published early in 1840 relative to these establishments, from which it appeared that the number of joint-stocks in England, at 1st January 1840, was 108, a considerable proportion of which had been instituted within the preceding ten years.

The number of partners in these banks varies from 50 to 1200, and may average about 300. There are half-a-dozen with less than fifty partners, the smallest number being seven. Fifty-eight of the banks have branches, and fifty have none. The branches, including the parent bank, are from two to sixty-seven in number. There are eight banks, which have more than twenty branches. The whole number of parent banks and branches is upwards of 650.

There are, besides, about 500 *private banks* in England—that is, banks having not more than six partners. Adding these to the joint-stock banks and their branches, the whole number of banking establishments will probably exceed 1150.

The issues of the joint-stock banks, when contrasted with the magnitude of the establishments, seem to us exceedingly small. According to the last return (Jan. 3, 1846), the notes in circulation of all the joint-stock banks were in value £3,162,742. This, divided by the number of banks (100), gives an average circulation of only £31,627 for each; or if we include the branches, the average for each office or establishment is only £7000. Supposing the money to be employed in discounting at 5 per cent., the annual profit on £3,162,742 would be only £158,137, or no more than £1581 to each establishment. It is evident that their profits must be chiefly derived from deposits, which they can employ at 5 per cent., while we believe they give only 2.

The issues of the *private banks*, by the same return, were £4,505,823, which gives an average of about £9000 for each establishment. It appears that the joint-stock banks, so far from superseding the private banks, have had no perceptible effect, if indeed any effect at all, in narrowing their issues.

The chief advantage conferred on the Bank of England, and constituting its charter of monopoly, is the privilege of being the only bank in London, or within sixty-five miles of it, having more than six partners, which can issue notes payable to the bearer on demand. The Bank has also the privilege of its notes being a legal tender by other banks for any sum above £5, so long as it pays its notes in cash on demand. This provision is a security to all other banks against the effects of sudden runs upon them for gold. It is ordained by act of parliament, that 'upon one year's notice, given six months after the expiry of ten years from the 1st of August 1834, and upon repayment by parliament of all sums that may be due from the public to the Bank at the time of the expiration of such notice, the exclusive privileges of banking granted by this act shall cease and determine at the expiration of such year's notice.' In 1844-5 there was necessarily a renewal of the peculiar privileges of the Bank of England, by which they were prolonged to 1855.

*Stocks—Stock Exchange.*—There are various kinds of stocks. Shares in a joint-stock company are called stock, and so are shares of debts due by government. No note or document is given by the government to loan contractors or holders of stock, as an evidence of their claims. At an office under charge of the Bank

of England, books are kept in which are inscribed the names of every creditor. The transfer of stock takes place on certain days, by the personal application of the holder, or his broker, having a power of attorney to act for him. In the transference, a seller may break down a large sum into many small sums equivalent in aggregate amount. If he hold £1000 of stock, he may cause the names of ten parties to be entered instead at £100 each. In these transfers no notice is taken of the market price of the stock; only the nominal amount, or stock at par, is recognised.

The ordinary sale of government stock is conducted in an apartment adjoining the Bank of England, called the Stock-Exchange, and the parties who manage all transactions of this kind are a body of stockbrokers. From the Stock-Exchange the public are rigorously excluded. No one is admitted except the subscribing brokers, who pay £10, 10s. per annum, and give securities to the extent of £800 against any deficiency in their transactions. The brokers are a respectable class of men, and seldom is any loss incurred on their account.

The market value of stock fluctuates according to the abundance or scarcity of money, and the likelihood of government paying back part of its borrowed money, or needing new loans. As the national debt can only be redeemed by buying up stock with any overplus revenue, any prospect of such being done by the apparently prosperous state of the finances causes the price of stock to rise; and if government were to announce that it was about to redeem a large portion of the debt, stocks would immediately rise to par. On some occasions, however, from the abundance of money, government has been in a position to announce, that unless the holders of certain stocks took a lower rate of interest, a new loan at a lower interest would be negotiated to pay off old debt. By this means alone several millions of interest per annum have been reduced, while the amount of debt remains much the same. Should it, on the contrary, appear that government is likely to borrow more money, from the prospect of a war, or some other untoward event, the price of stocks falls; and the price at one time fell as low as £57, 17s. 6d. per £100, when of course holders who were under the necessity of selling experienced prodigious losses.

In the buying and selling of stocks there is usually much deceit practised, which is known by the name of *stock-jobbing*. A writer in 'Blackwood's Magazine' for 1813 graphically notices this nefarious practice as follows:—'The practice of stock-jobbing consists in raising and circulating reports calculated to raise or depress the price of stock, according to the particular views of the individual. If he wishes, for example, to sell his stock or bills, he endeavours to propagate some report or other favourable to the issue of the war, and the establishment of peace, in order, if possible, to raise the price of stock; and if he wishes to buy, he propagates reports of a contrary tendency. It is painful to think that this abominable system is sometimes carried on by men whose rank and station in society, to say nothing of the obligation of morality and religion, might be expected to place them far above any such disgraceful acts; but in general, I believe, it is confined to men of desperate fortune and little character, who subsist by a species of gambling, to which the finance system of this country has opened a wide and extensive field. I allude to those men who make a practice of buying and selling stock, without actually possessing any, and whose transactions, therefore, are nothing more than wagers about the price of stock on a certain day. To explain the nature of the transaction by an example: I shall suppose that A sells to B a government bill of £100, or £100 of 5 per cent. stock, to be delivered on a certain future day, and that the price is fixed at £102. If, when the day arrives, the price of stock shall have fallen to £100, A would be able to purchase the bill in question for £100, while, in consequence of his bargain, B would be obliged to pay him £102 for it, so that A would gain £2. If, however, stock had risen to £104, B would still be obliged to give only £102, so that A

would lose £2; but instead of actually buying and selling the stock, the bargain is generally implemented by A paying to B, or receiving from him, the £2, or whatever may be the sum of loss or gain. In such a case as this, it is obviously A's interest that the price of stock should fall, and as obviously B's interest that it should rise, between the day of the bargain and that of settling; and hence the temptation held out to both to circulate reports favourable to their own particular views. B, or the buyer, is usually denominated a Bull, as expressive of his desire to *tos up*; and A, or seller, a Bear, from his wish to trample upon or *tread down*. The law of course does not recognise a transaction which proceeds on a principle of gambling; but a sense of honour, or, what is perhaps nearer the truth, *self-interest*, generally secures the payment of the difference, as the person who refuses to pay his loss is exhibited in the Stock-Exchange under the designation of a *lame duck*, a disgrace which is considered as the sentence of banishment from that scene of bustle and business.

This last-mentioned stock, variously termed *public securities*, or the funds, requires to be explained.

It has been stated in the article CONSTITUTION AND RESOURCES OF THE BRITISH EMPIRE (No. 62), that since the revolution of 1688, government has been in the habit of borrowing money to supplement the revenue raised by taxation, chiefly for the purpose of carrying on wars; and that the amount of money so borrowed, at present (1849) amounts to about £800,000,000, which is called the National Debt. This vast debt comprises two species of debts—the funded and unfunded debt.

The *unfunded debt* usually amounts to no more than from £10,000,000 to £20,000,000 of the whole: it is only temporary, and consists of promissory-notes of £100, £200, £500, and £1000, issued by the Chancellor of the Exchequer: these notes, called *Exchequer Bills*, bear a certain rate of interest per day: the interest varies from  $\frac{1}{4}$ d. to  $\frac{2}{4}$ d. per £100 per day. These bills are exchangeable from hand to hand, and form a kind of currency convenient to hold as property. Bankers make considerable investments in Exchequer Bills. They are sold from one holder to another at a premium or discount, according to the state of the money market. Exchequer Bills are either paid off by the government at stipulated periods, or funded—that is, added to the permanent funded debt.

The funded debt consists of various denominations of stock, bearing different rates of interest, according to the terms on which the respective loans were contracted. The chief stocks are the 3 per cent. consolidated annuities; the 3 per cent. reduced annuities; and the  $\frac{3}{4}$  per cent. annuities: the first-mentioned, which is ordinarily spoken of as the 3 per cent. consols, is the stock most in demand: it amounted in 1848 to £371,824,981. Whatever be the denomination of the stock, a description of one method of borrowing or funding will do for all. The Chancellor of the Exchequer receives power from parliament to borrow, for example, £10,000,000. This sum he divides into parts of £100 each; and he makes up his mind to pay a certain interest, say 3 per cent., for each £100. He now advertises for proposals to lend the gross sum required, these proposals to be sealed and sent to his office; all the proposals to be opened on a certain day: and the party who offers to give the largest sum in name of each £100 at the interest specified is to be accepted. The acceptor is called the 'contractor for the loan.' The sum usually offered in the name of each £100 varies in amount, according to abundance or scarcity of money at the time, the credit of the nation, and other circumstances. Between 1792 and 1802, when large sums were borrowed to carry on the war, the average sum given by contractors was £57, 17s. 6d. in name of each £100 which they lent. They gave £57, 17s. 6d., and got an obligation from government for £100. Latterly, as money has been more abundant, and the national credit improved, about £80 has been got for each £100 added to the national obligations. Whatever be the sum paid, the interest is reckoned on the nominal £100.

The contractor who undertakes the loan pays down a certain portion, and is allowed some months to pay the remainder: during this interval he probably sells parcels of the stock at a profit, till the whole or a large portion is disposed of. Sometimes two or more contractors unite in these speculations. Suppose £75 is paid in name of £100 at 3 per cent., this would be equal to 4 per cent. if a whole £100 were given. The plan of funding debt by taking less than is inscribed in the national books is justly censured by all writers as absurd and vicious. For an obligation to the extent of £10,000,000, the government may get in actual money not more than £7,500,000; and thus the nation is encumbered with a debt which it never properly incurred. According to Mr Porter, in his work on the 'Progress of the Nation,' the national debt has been increased by £83,223,162 in consequence of this most reprehensible mode of negotiating loans. The practice originated in state necessities, and in the terms on which loans are contracted. It is a stipulation, or at least understanding, that the borrowers (the government) are not to be called on to pay back the loan. The money is sunk, as it were, for ever, at interest; and this arrangement may be considered to operate so far detrimentally, as to prevent lenders giving the sum of £100 for a claim to that amount, unless at an excessive interest. Such may be the excuse tendered for a practice which accommodates the existing generation at the expense of succeeding ages.

*Banks in Scotland.*—The earliest banking institution in North Britain was the Bank of Scotland, instituted by a charter of incorporation from the Scots parliament in 1695. The original capital was £1,200,000 Scots, or £100,000 sterling. The amount was raised by shares differing in extent, from £1000 Scots, or £83, 6s. 8d. sterling, to £20,000 Scots. In 1774, the amount of stock was extended to £200,000 sterling: now it is £1,000,000 sterling, and the shares £100 sterling.

The establishment of the Bank of Scotland was of great service to the nation; the landholders borrowing notes, and bringing the country into cultivation, and a spur being by that means given to various branches of manufactures. The Bank of Scotland continued to be the only bank in the country till the year 1727, when a new and similar establishment was constituted under the title of the Royal Bank of Scotland, whose advanced capital is now £2,000,000. These two establishments engrossed all the respectable banking business in the country till the year 1746, when another association was formed, and incorporated by royal charter, with the title of the British Linen Company. The object of this association was at first to encourage the linen manufacture of Scotland, but gradually it fell into the course of common banking business, and now occupies a high station among these institutions. From £100,000, the capital of this bank has been raised to £500,000, where it has long remained stationary. By adroit management, it carries on an immense deal of business, and possesses as high credit as any banking establishment in Scotland.

These are allowed to take precedence of others erected in the subsequent part of last, and in the present century, either in Edinburgh or in the provinces; and their shareholders enjoy the privilege of being responsible only for their individual stock.

All the banks, with few exceptions, are joint-stock associations, and are banks both of deposit and issue. Except the few private houses, all issue notes of one pound and upwards, which are payable on demand at the office whence they are issued. It was at one time ordained that Scottish bank-notes should not be re-issued after they were three years old; but such a regulation is abrogated, and they are now sent out as long as they are in good condition. Almost all the modern notes are on specially-prepared paper, and are produced from plates of hardened steel, of such peculiar and intricate devices, that forgery cannot be attempted with success, or remain long undetected.

No periodical returns of their issues are made by the

## BANKS.

Scottish banks. But on turning to the evidence given before the parliamentary committees of 1826, we find the usual value of the small notes in circulation estimated by Mr Paul of the Commercial Bank, and Mr Blair of the British Linen Company, at £1,800,000, which is increased by a third at particular seasons, and when trade is brisk. The committee estimate the paper money of all kinds in circulation in 1826 at £3,309,082. But in the year of great speculation, 1825, they estimate the highest amount of notes in circulation at £4,683,000, the lowest at £3,434,000. By the law of 1844 (subsequently noticed) the maximum authorised issue is £3,087,209.

The following is a return of the joint-stock banks existing in Scotland at 5th January 1859, with the dates of their establishment:—

The Bank of Scotland, Edinburgh, 1695; the Royal Bank of Scotland, Edinburgh, 1727; the British Linen Company, Edinburgh, 1746; the Commercial Bank of Scotland, Edinburgh, 1810; the National Bank of Scotland, Edinburgh, 1825; the Aberdeen Bank, Aberdeen, 1825; the Ayr Bank, Ayr, 1825; the Dundee Banking Company, Dundee, 1825; the Dundee Union Bank, Dundee, 1825; the Dundee New Bank, Dundee, 1825; the Glasgow Bank Company, Glasgow, 1825; the Greenock Bank, Greenock, 1825; the Loith Bank, Leith, 1825; the Paisley Bank, Paisley, 1825; the Perth Banking Company, Perth, 1825; the Renfrewshire Banking Company, Greenock, 1825; the Paisley Union Bank, Paisley, 1809; the Aberdeen Town and County Bank, Aberdeen, 1825; the Arbroath Bank, Arbroath, 1825; the Dundee Commercial Bank, Dundee, 1825; the Glasgow Union Banking Company, Glasgow, 1830; the Ayrshire Banking Company, Ayr, 1831; the Western Bank of Scotland, Glasgow, 1832; the Central Bank of Scotland, Perth, 1834; the North of Scotland Banking Company, Aberdeen, 1836; the Clydesdale Banking Company, Glasgow, 1837; the Southern Bank of Scotland, Dumfries, 1837; the Eastern Bank of Scotland, Dundee, 1838; Edinburgh and Leith Bank, Edinburgh, 1838; being twenty-nine in all. Of the above list, several have been dissolved, or united with others, so that the number of Banks in Scotland empowered to issue notes by the law of 1844 is now only nineteen.

The business done by the Scottish banking-houses is prodigiously increased by the institution of their branches in the provincial and country towns. From those banks already noticed, which are situated in Edinburgh, and from two or three of the chief provincial banks, there were altogether deputed, not long since, about 360 branches, and this number is undergoing a regular increase. These subsidiary establishments are to be found in every town of any note, from the Borders to the most northern point of Scotland. They are conducted by resident wealthy or responsible merchants and others, who give securities for intrusions, and are subjected to a very rigorous supervision by inspectors, who are continually travelling about for this purpose.

The prudent and enterprising manner in which the business of banking is conducted in Scotland, has often been the subject of remark and commendation. Several reasons may be assigned for the remarkable stability of the Scotch banks. Each bank, before gaining credit with its neighbours, must show that it possesses a sufficient paid-up capital, with a reserve fund in London, on which orders for balances may be given. It is also the custom of the banks to exchange the notes of each other once or twice a week, by which means the notes are sent very speedily back to the issuers, and thus an over-issue on the part of any single establishment is prevented. There can only be an over-issue by all the banks in the country becoming equally reckless—a thing not likely to occur to any serious extent. A third cause of the stability of the institutions, is the liability of shareholders for the debts of the establishment. Excepting in the case of the three old-established banks above specified, all the shareholders in the various banks are liable not only for the amount of their own

shares, but for the shares of all the others; and the whole of their property may be seized to make up deficiencies. Although many of the shareholders are certainly not men of opulence, a number are so; and as their fortunes are good for the paper issued, the public runs no risk of injury. To strengthen this liability of shareholders, by the law of Scotland all heritable property, lands and houses, may be seized in satisfaction for their debts. As this is not the case in England, where personal or movable property can alone be taken by creditors, it would not be possible to establish banks in the south part of the island on the principle of the Scottish banks till the law touching heritable property underwent alteration.

Other causes, not of a legal nature, conspire to render the system of Scottish banking perfect. By reason of the circumscribed limits of Scotland, and the character of the people, a ramification of intelligence is created and preserved throughout the whole of society, altogether unknown in England, whereby the character, the wealthiness, and the conduct of the partners or directors of each bank, are made fully known to the rest. All seek, and all find, a knowledge of the management of each other. All are mutually on the watch; and symptoms of over-issues or other improprieties are spread with an amazing celerity, and have their immediate effect with the public.

In comparing Scottish banking institutions with those in England, and considering the different manner in which paper money has been employed by the two nations, the uniform security of the former appears almost miraculous. From the first issue of the bank-notes in 1704, till the year 1830, a single panic or general run did not occur in Scotland, although, during at least two-thirds of the intervening period, paper money had been used to the almost total exclusion of a gold currency. Partial and very temporary runs have assuredly been felt, from the effects of short-lived slander or mistaken notions, which have invariably been readily quashed; but in the course of a hundred and twenty-six years, there have only been two or three cases of banks failing to pay 20s. a pound (they paid 10s.), and four in which, after a short suspension of payments, all demands were liquidated. Their failure or stoppage, with the exceptions we mention, did not put the public to any loss; but this was to the injury of the shareholders, many of whom were reduced from affluence to poverty.

The peculiar character of Scottish banking was much infringed upon by an act of parliament passed in the year 1844, which limits the number of banks issuing notes to the number then existing; and obliges every bank of issue to keep a stock of sovereigns, according to a prescribed standard, which may be said to be at the rate of one sovereign for every two pound-notes issued. About a million of sovereigns thus lie locked up in the Scottish banks, for they are not seen in the circulation of Scotland. The loss of interest incurred by this arrangement amounts to about £50,000 annually. So serious a deduction from the profits of banking has had the effect of greatly limiting the extension of cash accounts and other accommodations. The number of the banks empowered to issue notes by this act is 19; their branches, 363; their capital, £11,240,000; and their authorised circulation, £3,088,209.

The common practice of making deposits of small sums in the banks, has further assisted in giving strength to the institutions. Each bank receives deposits of any sum above £10, for which a regular interest is given; and on this account the banks may be said to be the custodiers and traders upon all the spare capital of the country. Besides employing capital in discounting bills, lending money on heritable security, &c. the Scottish banks grant loans of fluctuating amount, called *cash accounts*. By a cash account is signified a process, whereby an individual, on entering into an arrangement with a bank, is entitled to draw out sums as required, to a stipulated amount, and by an implied condition, to make deposits at his convenience towards the liquidation of the same.

Cash accounts are said to have originated from the following circumstance:—A shopkeeper in Edinburgh, in the year 1729, found himself at times in the possession of more than a sufficient supply of ready money to carry on his trade, the overplus of which he consigned to the care of the neighbouring bank. But on other occasions, by reason of the length of the credits given to his customers, his money became so scarce, that after exhausting his bank deposits, he still felt himself in difficulties. Several dilemmas of this kind having occurred, he was prompted to make a proposal of a novel nature to the bank—to the effect that, if it would accommodate him in straits with small loans, he would always shortly afterwards make up such debits, and that the parties should come to a balancing of accounts at periodical intervals. It seems this proposal was acceded to. A cash credit, or liberty to draw to a certain extent, was instituted under approved securities; and thus originated a system which has been of immense benefit to bankers and traders, and is now followed over the whole of Scotland.

Cash credits are guaranteed by two sufficient securities, or the applicants give infirmity to heritable property in caution of the contingent debt, and when any such debt is liquidated, the deed is cancelled. The expense of expeding a cash credit varies according to the amount of the desired loan. One for £500 may be stated at about £15. The deed requires no renewal. At the end of every six, and in some cases twelve months, calculations are made of entries and debits; the interest for and against the bank—the one being a per cent. higher than the other—is added and balanced, and an account being then rendered, the balance, if in favour of the bank, is either paid up, or remains against the debtor at interest to his new account. In these cash credits the borrower is always of course at the mercy of the bank, which can call upon him at any time to balance his account, or, by his failing to do so, have recourse upon his securities.

Since 1729, cash credits have increased to an amazing extent. In 1826, it was computed that there were TEN THOUSAND in Scotland, varying in amount from £100 to £5000 each, but averaging from £200 to £500. Though originally designed for mercantile persons, they are now operated upon by farmers, manufacturers, house-builders, miners, lawyers, and all classes of traders and shopkeepers. During the last twenty years, it is extremely probable that, instead of decreasing, they have increased a thousand or two more.

*Irish Banks.*—The Bank of Ireland was established in 1783, and the same restriction—we quote Mr M'Culloch—as to the number of partners in other banks that formerly prevailed in England was enacted in its favour. Owing to that and other causes, the bankruptcies of private banks have been more frequent in Ireland than in England. In 1821, this restriction was repealed, as respects all parts of the country more than fifty Irish miles from Dublin. Since that period several banking companies, with large bodies of partners, have been set on foot in different parts of the country: of these the Provincial Bank, founded on the Scotch model, is among the most flourishing. By the act of 1844, the circulation of the Irish banks empowered to issue notes was £6,354,494.

Banks are in the present day established in every civilised country. In the United States of North America they have been instituted to a great extent, and frequently on most unsound principles, their notes being for very small sums, and these in few instances negotiable without a loss at a comparatively short distance from the place of issue; often, also, there has been a universal stoppage of cash payments, in consequence of over-issues of paper money, a sure testimony that the country was trading beyond what its actual capital warranted. It is this liability to exceed legitimate bounds which throws discredit on a *paper currency* in contradistinction to one of gold and silver. Were bank-notes in all cases to be a representative of property impledged for their payment on demand, and

could such property be instantaneously realisable, in the event of a run on the banks for payment, there would be little objection to their free issue. Except, however, in Scotland, where banking has been conducted on very cautious terms, notes have been on many occasions put in circulation representing nothing; and serious losses has been the consequence. Such is one of the great difficulties that beset the question of the CURRENCY.

*Savings'-Banks.*—These are banks for receiving and taking charge of small sums, the savings of industry, and have been instituted for the benefit of workmen and others, who may be able to spare a shilling and upwards from their weekly earnings. The first savings'-bank is understood to have been begun in Philadelphia in 1816, since which time they have been established in all parts of the United Kingdom, France, and other countries. Several acts of parliament were successively passed between 1817 and 1828 for the regulation of savings'-banks in England; and in the year last mentioned, the whole of these were consolidated in one statute (9 Geo. IV. chap. 92). This act, together with another passed in 1833, conferring additional and important privileges on savings'-banks (3 Will. IV. chap. 14), constitutes the existing law relative to these useful establishments; in 1835, the act was extended to Scotland. Savings'-banks established according to the provisions of these acts are entitled National Security Savings'-Banks, because the money deposited in them is paid into the Bank of England on account of government, whereby the nation becomes security for the amount of deposits—a security reckoned the best of all that could be given to depositors. The interest given by government on the sums so deposited is L.3, 5s. 0d. per cent. per annum, whatever may be the fluctuations in the value of the public funds during the term of investment. This rate of interest being higher than what government could otherwise borrow money for, it happens that the public are really losing money annually by their generosity. The rate of interest payable to the depositors is £2, 17s. 9½d.

Deposits of from one *shilling* to *thirty pounds* may be received by these banks; but no individual depositor is allowed to lodge more than thirty pounds in one year, or than £150 in whole. Charitable and provident institutions may lodge funds to the amount of £100 in a single year, or £300 in all; and Friendly Societies are permitted to deposit the whole of their funds, whatever may be their amount. Compound interest is given on the sums lodged, the interest being added to the principal at the end of each year in some banks, and at the end of each half-year in others, and interest afterwards allowed on the whole. Any depositor may receive, on demand, the money lodged by him, if it do not amount to a considerable sum; and even in that case it will be returned on a few days', or at most two or three weeks' notice. Practically, payment is always made on demand. The wisest and most effectual provisions are made for insuring the proper management of the affairs of the banks, so that those who intrust them with their money may place implicit reliance on its safety. Each depositor is provided with a small book, in which his deposits are entered, and the amount of his interest marked. On the 20th of November, the interest is added in the bank books whether the depositor call or not. It is computed for the full term, and upon every fifth fraction of a pound. Depositors have thus the advantage of having their principal sum gradually increasing at 3 per cent. compound interest. So successful has been the establishment of the savings' banks, that the amount of deposits, chiefly the property of the humbler classes, is now upwards of £32,000,000, and is annually increasing. In 1845, the number of individual depositors was considerably above 1,000,000. For further information respecting these beneficial institutions, the reader is referred to a subsequent number of the SOCIAL ECONOMICS OF THE INDUSTRIOUS ORDERS.

# POPULATION—POOR-LAWS—LIFE-ASSURANCE.

## POPULATION.

THE rate at which human beings naturally increase, the proportion which this increase bears to the means which exist for their subsistence, and the laws which operate to bring the increase and the means of subsistence into conformity, were subjects scarcely reflected on by our ancestors, but have been matter of keen discussion and controversy during the first thirty years of the present century.

As far as population was at all thought of in former times, the prevalent doctrine was, that the greater the numbers of a nation, the stronger was the state, and the more likely was that country to be a scene of both agricultural and commercial industry. So useful were numbers considered for increasing the means of subsistence, and also of national defence, that in many countries it was thought proper to make laws for encouraging matrimony, and to put bounties on all families exceeding a certain number. So lately as the time of Louis XIV., pensions were awarded in France to individuals who had ten or more children.

Dr Adam Smith, in his 'Wealth of Nations,' was perhaps the first to suggest anything like a law as regulating the increase of population. He remarked that 'the demand for men, like that for any other commodity, necessarily regulates the production of men; quickens it when it goes on too slowly, and stops it when it advances too fast. It is this demand,' says he, 'which regulates and determines the state of population in all the different countries of the world—in North America, in Europe, and in China; which renders it rapidly progressive in the first, slow and gradual in the second, and altogether stationary in the last.'

### VIEWS OF MR. MALTHUS.

The preceding hint, for it can be regarded as little else, is said to have been what suggested the celebrated essay of Mr Malthus, which first appeared in 1798, but was almost reconstructed in a second edition in 1803. There was something so startling in the views of this writer, and at the same time so much plausibility in his arguments, distressing as they were to natural feelings, that his work attracted general attention, and many of the ablest thinkers and writers of the day became converts to its main doctrines.

An abridgment of Mr Malthus's views, given in the 'Edinburgh Review' for August 1810, sets out by showing that 'the rate of population is by no means the same in all parts of the world.' The variations in the rate are universally preceded and accompanied by variations in the means of maintaining labourers. 'Where these funds are rapidly increasing, as in North America, the demand for an increasing number of labourers makes it easy to provide an ample subsistence for each; and the population of the country is observed to make rapid advances. When these funds increase only at a moderate rate, as in most of the countries of Europe, then the demand for labourers is moderate; the command of the labourer over the means of subsistence is consequently much diminished; and the population is observed to proceed at a moderate pace, varying in each country, as nearly as may be, according to the variations in the funds for its support. Where these funds are stationary, as we are taught to believe is the case in China, and as has certainly been the case in Spain, Italy, and probably most of the countries of Europe during certain periods of their history, there the demand for labour being stationary, the command of the labourer over the means of subsistence is comparatively very scanty, and population is observed to make no perceptible progress, and sometimes to be even diminished.

No. 83.

In the second place, it is a fact equally notorious, that the actual increase of the funds for the maintenance of labour does not depend upon the mere physical capacity of any particular country to produce food and other necessaries, but upon the degree of settled industry, intelligence, and activity, with which these powers are at any particular time called forth. We observe countries possessing every requisite for producing the necessaries and conveniences of life in abundance, sunk in a state of ignorance, indolence, and apathy, from the vices of their governments, or the unfortunate constitution of their society, and slumbering on for ages with scarcely any increase in the means of subsistence, till some fortunate event introduces a better order of things; and then the industry of the nation being roused and permitted to exert itself with more freedom, more abundant funds for the maintenance of labour are immediately provided, and population is observed to make a sudden start forwards, at a rate altogether different from that at which it had previously proceeded.

This seems to have been the case with many of the countries of Europe during some periods of their history; but is more particularly remarkable in Russia, the population of which, though very early inhabited, was so extremely low before the beginning of the last century, and has proceeded with such rapid steps since, particularly since the reign of Catherine II.

It is also a fact that has often attracted observation in a review of the history of different nations, that the waste of people occasioned by the great plagues, famines, and other devastations to which the human race has been occasionally subject, has been repaired in a much shorter time than it would have been if the population, after these devastations, had only proceeded at the same rate as before. From which it is apparent, that after the void thus occasioned, it must have increased much faster than usual; and the greater abundance of the funds for the maintenance of labour, which would be left to the survivors under such circumstances, indicates again the usual conjunction of a rapid increase of population with a rapid increase of the funds for its maintenance. In England, just after the great pestilence in the time of Edward III., a day's labour would purchase a bushel of wheat; while, immediately before, it would hardly have purchased a peck.

With regard to the minor variations in the different countries of Europe, it is an old and familiar observation, that wherever any new channels of industry and new sources of wealth are opened, so as to provide the means of supporting an additional number of labourers, there, almost immediately, a stimulus is given to the population; and it proceeds for a time with a vigour and celerity proportionate to the greatness and duration of the funds on which alone it can subsist.

From these and other premises, Mr Malthus laid it down as a proved fact, that population tends to increase at the rate of a doubling every twenty-five years. He at the same time endeavoured to show that, as man begins to use the best lands first, or in other words, those of which he can reap the fruits with least labour, and then has to go to worse and worse, it becomes always more and more difficult to obtain the means of subsistence for increasing numbers. He concluded that, at the utmost, the means of subsistence would be found, at the end of each successive quarter of a century, to have increased only at the rate of double for the first, triple for the second, quadruple for the third, and so on. Thus (said he) while population would go on increasing in a geometrical ratio—that is, as 1, 2, 4, 8, 16, 32, 64, 128, &c.—food would increase only in an arithmetical ratio—that is, as 1, 2, 3, 4, 5, 6, 7, 8, &c.—and the consequence

513

lions, there would be food for 10,000 millions only, or but a fiftieth part of the number!

Considering, then, that there is a power and a tendency in human beings to increase so rapidly, and that, in point of fact, it is only in a few favoured spots that they do increase at such a rate, Mr Malthus concluded that there must be some counteracting agencies, or checks, in constant operation, in almost all communities, to restrain population at a lower rate of increase, or keep it stationary. In looking about to discover these checks, he satisfied himself that they were of two orders: first, there was the mortality produced by the effects of deficient food and of wicked passions; these he called *positive checks*: then there was the check produced by a prudent forethought in human beings, leading them to avoid marriage, on account of the little prospect of being able to rear a family in comfort; this he called the *preventive check*.

Arriving at this point, Mr Malthus and his followers proceeded to show how their doctrines were applicable for the benefit of communities. It was held that there could be no choice between the two kinds of checks: it was clearly preferable that population should be restrained by the preventive check. 'It is observed,' says the Review already quoted, 'in most countries, that in years of scarcity and dearth the marriages are fewer than usual: and if, under all the great variations to which the increase of the means of subsistence is necessarily exposed from a variety of causes—from a plenty or scarcity of land, from a good or a bad government, from the general prevalence of intelligence and industry or of ignorance and indolence, from the opening of new channels of commerce or the closing of old ones, &c. &c.—the population were proportioned to the actual means of subsistence, more by the prudence of the labouring classes in delaying marriage, than by the misery which produces premature mortality among their children, it can hardly be doubted that the happiness of the mass of mankind would be decidedly improved.

It is further certain, that, under a given increase of the funds for the maintenance of labour, it is physically impossible to give to each labourer a larger share of these funds, or materially to improve his condition, without some increase of the preventive check; and consequently that all efforts to improve the condition of the poor, that have no tendency to produce a more favourable proportion between the means of subsistence and the population which is to consume them, can only be partial or temporary, and however plausibly humane, must ultimately defeat their own object.

It follows, therefore, as a natural and necessary conclusion, that in order to improve the condition of the lower classes of society, to make them suffer less under any diminution of the funds for the maintenance of labour, and enjoy more under any actual state of these funds, it should be the great business to discourage helpless and improvident habits, and to raise them as much as possible to the condition of beings who "look before and after." The causes which principally tend to foster helpless, indolent, and improvident habits among the lower classes of society, seem to be despotism and ignorance, and every plan of conduct towards them which increases their dependence and weakens the motives to personal exertion. The causes, again, which principally tend to promote habits of industry and prudence, seem to be good government and good education, and every circumstance which tends to increase their independence and respectability. Wherever the registers of a country, under no particular disadvantages of situation, indicate a great mortality, and the general prevalence of the check arising from disease and death over the check arising from prudential habits, there we almost invariably find the people debased by oppression and sunk in ignorance and indolence. Wherever, on the contrary, in a coun-

try, there is a constant and a prudent check from prudential habits above that from premature mortality, there we as constantly find security of property established, and some degree of intelligence and knowledge, with a taste for cleanliness and domestic comforts, pretty generally diffused.

Nor does experience seem to justify the fears of those who think that one vice at least will increase in proportion to the increase of the preventive check to population. Norway, Switzerland, England, and Scotland, which are most distinguished for the smallness of their mortality, and the operation of the prudential restraint on marriage, may be compared to advantage with other countries, not only with regard to the general moral worth and respectability of their inhabitants, but with regard to the virtues which relate to the intercourse of the sexes. We cannot, as Mr Malthus justly observes, 'estimate with tolerable accuracy the degree in which chastity in the single state prevails: our general conclusions must be founded on general results; and these are clearly in our favour.

We appear, therefore, to be all along borne out by experience and observation, both in our premises and conclusions. From what we see and know, indeed, we cannot rationally expect that the passions of man will ever be so completely subjected to his reason, as to enable him to avoid all the moral and physical evils which depend upon his own conduct. But this is merely saying that perfect virtue is not to be expected on earth, an assertion by no means new, or peculiarly applicable to the present discussion. The differences observable in different nations, in the pressure of the evils resulting from the tendency of the human race to increase faster than the means of subsistence, entitle us fairly to conclude, that those which are in the best state are still susceptible of considerable improvement, and that the worst may at least be made equal to the best. This is surely sufficient both to animate and to direct our exertions in the cause of human happiness; and the direction which our efforts will receive, from thus turning our attention to the laws that relate to the increase and decrease of mankind, and seeing their effects exemplified in the state of the different nations around us, will not be into any new and suspicious path, but into the plain beaten track of morality. It will be our duty to exert ourselves to procure the establishment of just and equal laws, which protect and give respectability to the lowest subject, and secure to each member of the community the fruits of his industry; to extend the benefits of education as widely as possible, that to the long list of errors from passion, may not be added the still longer list of errors from ignorance; and, in general, to discourage indolence, improvidence, and a blind indulgence of appetite without regard to consequences; and to encourage industry, prudence, and the subjection of the passions to the dictates of reason. The only change, if change it can be called, which the study of the laws of population can make in our duties, is, that it will lead us to apply, more steadily than we have hitherto done, the great rules of morality to the case of marriage, and the direction of our charity; but the rules themselves, and the foundations on which they rest, of course remain exactly where they were before.'

This must be considered as the mildest possible exposition of the application of Mr Malthus's doctrines; his theory almost necessarily led to some other practical inferences, of a kind to which it is not so easy for a humane mind to assent. It came to be held, for instance, that where the preventive check had not operated, it was quite legitimate to allow the positive to come into operation. A human being, who had come into existence undemanded by the state of the funds for subsistence, was to be told that the places at Nature's table were all occupied, and there was no cover for him. To the man who married when there was a redundancy of population, 'all pariah assistance,' said Mr Malthus, 'should be most rigidly denied; and if the hand of

private charity be stretched forth in his relief, the interests of humanity imperiously require that it should be administered very sparingly.' These notions were adopted very generally by a class of political economists, and for twenty years they were in vogue in England, where the notorious abuses of the old poor-law had prepared the minds of many for taking extreme views with regard to public charity. But it was impossible for the great bulk of the community to give a cordial reception to doctrines so violently in opposition to the dictates of the natural feelings.

#### OBJECTIONS TO MR. MALTHUS'S VIEWS.

A reaction at length took place against the Malthusian theory, and views having an opposite tendency were presented by various writers, the most distinguished of whom was Mr. M. T. Sadler, whose work, entitled 'The Law of Population,' appeared in 1830.

By these writers it was represented that in America and the Australian colonies there was an evident tendency in subsistence to increase in a more rapid ratio than population, inasmuch that flocks and herds became a drug, and it was not uncommon in Brazil to use fat carcases of mutton as fuel in limekilns. The only difficulty experienced in those regions was in obtaining a market for the vast amount of produce not needed by the native population. Here, it was said, is a clear case in disproof of the proposition, that population always tends to increase more rapidly than food.

As for the geometric ratio of the human increase, by which so great an alarm had been excited, what was it, after all, but a different form of the obvious truth, that the more people there were, there would be the more parents, and consequently the more children? Suppose ten families, existing in 1800, having become twenty in 1825, it might certainly be expected that the addition between the last date and 1850 would be other twenty, not ten merely, seeing that the start was not from ten, as it had been before, but from twenty. Such is but an unavoidable consequence of population swelling by multiplication, and not by addition. But if the human family follows this ratio of increase, so do all the orders of organic beings, animal and vegetable; sheep, oxen, and hogs increase at the geometric ratio as well as mankind, and what is more, they begin to multiply at a much earlier period of life. Poultry, for instance, could probably multiply themselves a million of times before a couple of the human race could do so once. The vegetable food of man is capable of a still more rapid increase. Wheat generally returns from ten to twenty fold in one year. The produce of a single acre of this grain, increased year after year in the ordinary way, would require only fourteen years to reach an amount which would occupy the whole cultivable surface of the globe. And as it is with wheat, so is it with most of the other plants on which we depend for food, either for ourselves or for the animals which become food to us. So that, instead of there being any such disagreement between the natural possibilities of increase in human beings and subsistence, as Mr Malthus and his disciples insisted on, there would appear to be a discrepancy in exactly the contrary way; that is to say, the means of subsistence appear to be capable of a much more rapid increase than human beings.

But—the Malthusians object—when the best soils are all under cultivation, it is necessary to resort to the inferior. These require more labour and afford less return. There is therefore a *decreasing fertility* in the country, while its population is always increasing. To this it is replied by the opposite party, that while worse and worse soils are in the course of being resorted to, better and better modes of culture are coming into operation, so as to make perhaps a third-rate soil capable of producing as much, by a certain amount of labour, as a second-rate soil was a few years before, and so on with the other qualities, each being raised a degree in the scale by every fresh effort of human ingenuity. In point of fact, the best British soils do now bear four times the quantity of grain which they did a

few centuries ago, and millions of acres then deemed unfit for tillage now produce as much by the same degree of labour as the best soils did at that time. Add to this improved modes of culture, which lessen the amount of labour, the application of stimulants hitherto unknown, and also more economical modes of sowing and preparing food, and you have a ratio of increase in the means of subsistence equivalent to anything anticipated in the progress of population.

The Malthusians, however, were said by their opponents to derive the strength of their case from limiting their views to a certain region. Their propositions, it was admitted, might be true with regard to a population shut up in a certain small space, without any connection with what was beyond. But such a population never existed, and therefore the apprehended evils never could take place. From the earliest notices we have of the human family, it appears to have been their custom to spread abroad over the soil, when they found that food could be more easily obtained at a distance from the natal spot than at the natal spot itself. The original command given to man, *to increase and multiply and replenish the earth*, is only in accordance with what has always appeared as a tendency of the race. It is probable that at the present time not above one-hundredth part of the earth's surface is cultivated, and not one-hundredth part of that cultivated in a scientific or advantageous manner; while, from what has taken place, we may reasonably calculate upon the productiveness of the best-cultivated parts being yet greatly increased. With such an almost indefinite field still before us, it seems absurd to be under any anxiety as to the supposed tendency of the human family to a too rapid increase. The superabundance of one district has only to go to some yet unpeopled spot, or to exert ingenuity and industry to raise more food from that which they do occupy, in order to maintain themselves in comfort. There is another means whereby it may chance that a superabundant population can support itself in the native locality, though the productiveness of that locality falls short of the demand for food. If it possess advantages for manufactures, it can exert its industry in that way, and exchange the products for food raised in other countries, where subsistence exceeds population, and advantages for manufactures do not exist.

The opponents of Mr Malthus combated his notion of checks on moral and religious grounds; and here, certainly, the natural feelings of mankind greatly favoured their views. It was held as an impeachment of that system of wisdom and benevolence seen throughout all nature, that one of the most powerful tendencies of human beings should be supposed to require being put under an absolute arrestment, upon the penalty of its otherwise leading to misery in the individual, and embarrassment in the community. It was held that the preventive check, supposing it to be capable of operating without an increase of immorality, was necessarily attended by an abridgment of human happiness, in as far as it involved a denial and repression of the domestic affections. Its cruelty was also partial, for it bore solely on the poorer classes, to whom celibacy is a greater hardship than to the rich. And even supposing that it could be morally carried into effect, so as to keep down population at a certain level, it was, after all, an uncalled-for interference with Divine arrangements, which, from all analogy, as well as from their practical effect, might be supposed as having been designed for good ends. For do we not see that the charge of a family acts in all well-constituted minds as an incentive to industry? and can we doubt that equally will a growing population tend, in ordinary circumstances, to increase the industry of a nation? Contemplated thus, the tendency to increase would appear as a means, in Providence, to stimulate men and nations to the utmost possible exertions for the improvement of the materials placed at their command, so that no faculty of their being might lie waste, and no power of physical nature remain useless and unenjoyed. Sup-

## GENERAL OBSERVATIONS.

Such is an outline of the arguments which have been advanced on both sides of this important question. It must, we think, be generally evident to new and dispassionate inquirers, that there is some truth in the views of both parties, but that the full and exact truth has not been stated by either. For arriving at a sound conclusion on the subject of population, the means do not perhaps exist in the present imperfect state of statistical science; but in the meantime we may present a few considerations which have occurred to ourselves.

It appears to us to be only an assumption that there is everywhere a tendency to double the population every twenty-five years. We certainly see that such has been the case in North America; but possibly this is considerably owing to temptations which are presented by the state of the country, labour being so expensive in all such regions, that a bounty may be said to be put upon the possession of a numerous family. Perhaps the natural tendency is there drawn into something approaching to an unnatural state of activity.

Allowing that the increase is no more than what the natural inclinations of that people dictate, it is by no means clear that all nations possess natural inclinations in the same degree. We know that many features of human character are manifested in very different degrees in different nations; and it is therefore not unreasonable to suppose that there are also national differences in those feelings which lead to the increase of the human family. Individuals, it is well known, are characterised very differently in this respect. There are also obvious differences in families, the peculiarity being apparently hereditary. Why, then, may there not be differences also in nations? Perhaps the light to be derived from the history of families and of individuals, has not yet been taken sufficient advantage of for the illustration of this question. A careful collection of facts would probably show a far greater amount of natural causes for the obstruction of population, and these altogether independent of Mr Malthus's checks, than philosophers are at all prepared for.

The history of many families of historical note uncontestedly shows that often, with all external advantages, there is surprisingly little tendency to increase. The extinct peerage and baronetage of England forms, it will be recollected, a pretty large book. In that high rank there is greater longevity, and consequently, it may be presumed, better health, than in lower grades; yet the line often fails for lack of heirs. To take a few cases which happen to be familiar to us: When George, fifth Duke of Gordon, died a few years ago, it was necessary, in order to get an heir for one of his titles destined to heirs-male, to go back to the ancestor who had flourished in the time of the civil war, all the intermediate persons having failed to send down male heirs, though many had had several sons born to them. When the main line of the Keith Mareschal family became extinct in 1778, it was necessary to go back for a male representative to a collateral line which sprung off from the main one at the end of the fifteenth century, although many goodly representatives and male cadets had flourished in the interval. It is well known that no representative of the royal family of Stuart since Robert III., who died in 1406, has at this time legitimate male descendants. In short, it would appear that families may exist in flourishing circumstances for hundreds of years, and after all, the male progeny may become extinct, and the name of the race be in time looked for in vain. The contrary is, no doubt, often true: for example, the male progeny of the above-mentioned Scottish king exist in great numbers, in all conditions of life. But while it is the lot of some to be thus multiplied exceedingly, it is not less true that many individuals leave not one copy of themselves; and that even whole clans and

means necessary to a comfortable existence.

An illustration occurs to us, to which, we believe, many of our readers will readily find parallels within their own knowledge. A citizen of Edinburgh, who died about thirty years ago, had seventeen sons and daughters, most of whom reached maturity. All the members of this second generation have ever since been in comfortable circumstances: some are now dead; the rest have passed on to such periods of life that it is not to be expected that children will hereafter be born to any of them. And what is the number of the third generation of this family? Only eight, the offspring of two marriages. Thus showing that the progeny of a single pair may look large at the first remove, but shrink at the second. We may add, that this family appears decidedly marked by much less than the average of a tendency to matrimonial life. As facts are what is here wanted, the writer may be excused for mentioning a circumstance in his own family history. He can trace its course with tolerable clearness for two hundred years; and is pretty well assured that, during the whole of that time, till the generation immediately preceding himself, no representative of the family had more than one son to transmit its name and property. Local antiquaries are familiar with instances of families once numerous in a certain province, but now extinct. The present writer has reason to believe that his own family existed for more than twice the space of time above-mentioned in one particular place; yet the county in which that place is situated does not now contain one person of the name.

Were it even admitted that communities are naturally equal in respect of the inclination and power, it still remains to be shown that these tend to be equally manifested in all social circumstances. The readiness with which the Malthusians have assumed that this is the case, seems to us highly unphilosophical.

In dense communities, where all social circumstances are in the best condition, there are many enjoyments not known in ruder states of society. It may not merely be that these enjoyments compensate for the want of others, but they may absolutely take away or supplant the inclination for those other enjoyments, so as to make the 'checks,' as far as they are concerned, a mere empty name. Following out this line of argument, supposing it to be sound, we arrive at the conclusion, that when a country becomes filled up with people, it is also in general attended with circumstances which moderate the tendency to increase, without that being felt as any hardship.

The noted case of Ireland tends to support this hypothesis. Singularly deficient in the compensatory or rather preclusive conditions, this country has long been remarkable for the rapid increase of its population. The common people, reduced to a degree of poverty which admits of no hope, and exposed to a constant privation of all the ordinary solaces of life, are driven to matrimony as the only comfort in their power, just as others in their condition are driven to the use of intoxicating liquors. The consequences lead to greater poverty, and greater poverty tends to increase the evil; and thus will such a system of things go on, until counteracting agencies are brought into operation. Such agencies are now apparently at work in Ireland; and however painful and distressing the ordeal, wealth and its enjoyments will ultimately increase according to the capabilities of the country and the amount of industry expended upon their development. Even under the obstruction of recent visitations and difficulties, circumstances are improving, and we may therefore hope speedily to see the advance of population in that country less of a wonder than it has been.

Granting the above arguments to be sound, it follows that the stationary condition of the population of old countries is not necessarily to be supposed to be attended with either the hardship of restraint or an extraordi-

## POOR-LAWS.

nary mortality. If the wealth and ordinary solacements of a people in such circumstances are not in the way of being lessened, that people may fairly be presumed to be as well off in all necessary respects as the rapidly-increasing multitudes of America.

Where we see the inhabitants of an old country rapidly increasing, we must come to one of two conclusions: either that that country is in a flourishing state, so that there is a kind of bounty put upon children, or that it is in a state of such wretchedness, that the intercourse of the sexes is the only attainable enjoyment. With regard to Ireland, we presume there can be no doubt of its liability to pass into the latter category. But the rapid increase of the English people in the last forty years will probably be the subject of a doubt. To determine this question, it might be inquired if the increase of the agricultural products and of the manufacturing industry of the country has been in an equal ratio, and if labouring men, skilled and unskilled, can now obtain for their labour as large a share of the comforts of life as formerly. Notwithstanding popular declamations to the contrary, we suspect this to be the case, and consequently believe the increase of population in England to be, upon the whole, of a healthy and satisfactory description.

### POOR-LAWS.

In all stages of society there has existed a class emphatically termed the *Poor*, composed of persons who, but for the charity of their neighbours, would be nearly or totally destitute, being themselves unable, or all but unable, to supply their own wants. It is easy to see how this has been and must be; for, from accidents in the operation of the natural laws presiding over the birth of individuals, some come into the world without the usual gifts of body and mind required for obtaining a sufficient subsistence; the accidents of life deprive others of the use of their full powers; many reach an infirm old age without having laid up a store to help them over it; the consequences of vice and error—of all those countless temptations which beset human nature, and from which no one is altogether safe—leave many in a helpless state; finally, in the imperfection of all political institutions, there are circumstances which press severely upon classes and persons, tending to make their own efforts for their subsistence insufficient. The operation of accidents upon one class of parents, and the vices and neglect of others, likewise leave many young and helpless children in a state in which they would be destitute but for the aid of neighbours. All of these causes being inherent in human nature and in society, we may be assured that 'the poor we shall have with us always,' however it may be possible, by judicious and humane efforts, to keep their numbers within comparatively moderate bounds.

In an early state of society, the relief of the poor is left to the operation of benevolence amongst individuals; and the destitute are either succoured by those locally near them, or go forth to beg relief in a wider circle. Generally, the efficacy of benevolence for this end is made the greater, in consequence of the succour of the poor being set forth as a duty in almost all religions. In addition to occasional and particular acts of charity, donations are made and legacies left for the purpose of affording a more or less regular and systematic relief within certain bounds. As society, however, advances, it is found that the charity of individuals is either an insufficient means of succouring the poor, or is attended with certain inconveniences. The classes of society becoming more detached from each other, cases of destitution make appeal, almost exclusively, to the parties nearest in poverty; while the rich, and the comparatively rich, are saved from all concern in the matter, merely because local and social circumstances spare them a personal connection with it. A relief by benevolence is found to be oppressive to those who have kind feelings, while the niggardly and un-

generous escape. A dense and highly-artificial state of society rendering it impossible to keep watch over particular cases of destitution, the relief afforded is unavoidably partial and unequal—no one knowing the real needs of a petitioner, or how far he is relieved by others; so that a door is opened for the practice of gross imposture, while the more modest poor are probably the least liberally treated. It is also generally found that this state of society is attended with an increase of the numbers of the poor, rendering individual efforts insufficient, and tending to such disorders, that a public provision becomes necessary as a matter of police. A new principle is then evolved from the natural fact of the existence of a poor class—namely, that the community cannot be safe from imposture, spoliation, the propagation of disease, and other kindred evils, unless it combine to assure itself that no person in the country shall want the necessaries of life.

It is then that states begin to make arrangements for the regular relief of the poor; and generally these arrangements are of a more or less advanced and efficient nature, in proportion to the advanced social condition of the respective countries. In most of the Catholic states of Europe the system adopted consists simply in the ministers of religion taking charge of the voluntary contributions of the people, and administering them to the best of their ability. In Portugal, Sardinia, Venice, France, Belgium, and some other countries, the same system exists, excepting only that the ministers of religion are superseded in their charge by officers appointed by the state. We need scarcely remark that the single fact of the funds being voluntary, renders it impossible, as to any of these countries, to be certain that the provision for the poor is sufficient in amount. In England, Ireland, Prussia, Bavaria, Wurtemberg, Mecklenberg, Berne, Russia, Denmark, Sweden, and Norway, the principle is recognised that a compulsory provision ought to be made to insure that all the members of the community shall have the means of subsistence. In England, this has been in operation for nearly three centuries; but in most of the other countries enumerated it is of comparatively recent adoption. In America, all the states of the Union which are of English origin have, from their commencement as colonies, adopted this principle. In Scotland, laws for a compulsory provision have existed nearly as long as in England, but have not, till very recently (1845-46), been carried out into anything like a general system.

### ARRANGEMENTS FOR THE POOR IN ENGLAND.

Acts respecting the poor in England only made arrangements as to the places in which they should beg, until, in 1536, immediately after the dissolution of the religious houses, by which the poor had previously been in a great measure supported, it was found necessary to make an effort to repress the enormous prevalence of vagrancy, by enacting that head officers in parishes, towns, and counties, should take charge of the impotent poor, and collect alms for their support, and at the same time use force to compel able-bodied mendicants to work for their own livelihood. This and subsequent acts of a similar character appear in a great measure to have failed in their object, chiefly perhaps from the severity of the penalties imposed for disobedience. In 1572, we find the first trace of compulsory assessment for the poor—a measure then resorted to, apparently, because all other means of collecting money had proved insufficient.

It was, however, by the famous act 43 Elizabeth, c. 2 (1601), that the basis of the present system of poor-relief in England was laid. The professed objects of this law were, 'to set the poor to work, to relieve the lame, impotent, old, and blind, and to put out their children as apprentices.' To attain these objects, the inhabitants of every parish in the country were required to raise a fund sufficient to maintain their own poor; and the administration of this fund was placed in the hands of parish overseers, under the control of

reiner should be subjected to a test, to prove that the alleged want was not the result of an indolent disposition: such persons were to receive relief only on condition that they should work for it. To make this rule certain of operation, an act passed eight years after (7 Jac. I. c. 4) ordered the building of houses of correction, to be provided with cards, mills, and other implements, and where the vagrant able-bodied poor should be set to work. This may be considered as the origin of the workhouse system in England.

It is clear, from the statutes of this period, that the chief evil which the legislature found itself called upon to consider and provide for, was the indolent and vagrant disposition of a large section of the people. It was not, as now, that many men occasionally find a difficulty in getting work, but that many were unwilling to work, preferring to wander about the country in idleness. It appears that these vagrants were accustomed to stay only for a short period in one place, and to flit about to wherever they thought they would be best supported; nor can it be doubted that, in lonely places, they would not be backward to use means for terrifying the lieges into contributions for their benefit. That, in such circumstances, these people would want all moral culture, and be a source of danger to the community, is of course evident. It required many years' operation of the law to reduce this evil; but at length, about the end of the seventeenth century, it seems to have been considerably lessened. The same class of persons then began to prefer the benefits to be obtained through the claim which the law gave them upon their native parishes, and the evil of vagrancy was gradually exchanged for one of another but less grievous kind—an inclination to a timid and slothful dependence on the relief to be obtained at one fixed place.

The houses of correction were mainly penal establishments; and it was not till 1723 that workhouses, as now understood, were established. An act passed in that year enabled parishes, either singly or in union, to provide themselves with houses wherein to employ the poor; and enacted that, in case any person refused to be relieved in those houses, he should not be entitled to any other relief. This might be severe upon the real pauper, but it effectually unmasked the voluntary one and the impostor, and proved a protection to parishes against the orders of justices, over-liberal of money not their own. The operation of this law was so favourable to the public, that some began to imagine that paupers might even become profitable; and this was partly the cause of an act (22 Geo. III. c. 83) in 1782, usually called *Gilbert's Act*, which threw upon guardians the duty of finding work for the poor near their own residences, and making up what was required for their subsistence out of the poor-rates. The use of the workhouse as a test of real indigence and inability was thus in a great measure undone, and all its benefits in repressing a pauper population lost. *Gilbert's Act* may be said to have been the foundation of all the pecuniary oppression to the public, and all that demoralisation of the lower classes for which the English poor-laws were latterly so remarkable.

In 1795, the price of wheat, which, at an average of the three preceding years, was 54s., rose to 74s., and the condition of the labouring-classes consequently became one of considerable privation and hardship. Instead of temporary measures for getting over a temporary difficulty, one of a permanent nature was adopted. The magistrates of Berkshire in that year issued tables, stating what the wages of a labourer per week ought to be, according to the magnitude of his family and the price of the gallon loaf; directing at the same time the overseers, and others concerned in the management of the poor, to regulate their allowances accordingly. The minimum weekly wages of an unmarried labourer, supposing the gallon loaf to sell at one shilling, were set down at 3s.; when married, and having one child, wages were to be at least 6s.; if he had five children,

gallon loaf rising to 12s. 6d., the wages of an unmarried man were not to be less than 4s. 3d. a week; while the wages of a married man, with a single child, were not to be less than 8s. 3d.; and those of a married man with seven children not less than 20s. 3d. These regulations, which remind one of the ignorant legislation of the fourteenth century, were made binding, universal, and permanent, by an act passed in the ensuing year (86 Geo. III. c. 25). It cannot fail to be remarked what a mean opinion of the character of the labouring-classes of England must have been entertained amongst the more enlightened men of that day, when it was thus thought necessary to undertake for them some of the simplest duties which they owed to themselves, and to make them everywhere pensionaries upon the public for a considerable part of their subsistence. As an attempt to secure to a portion of the community the same supply of food in scarce as in plentiful years, and consequently to relieve them from the necessity of those retrenchments by which a deficient supply is distributed over the whole year, and absolute famine averted, the act was further liable to be considered as a gross absurdity. The evils of the regulations themselves were increased by peculiarities in the administration, by which the labouring-classes became a means of enabling one class of rate-payers to carry on a constant warfare against the pockets of another. The general evils of the poor-laws were much aggravated by the arrangements with respect to settlement; virtually, the labouring-classes were imprisoned in the parishes of their nativity, or where some subsequent circumstance, as apprenticeship, marriage, and inheritance, had given them a claim. Thus the population was distributed, not as required by the demand for labour, but as certain accidental circumstances might direct; and accordingly there were often hordes of useless labourers at one place, and a great amount of labour without hands to undertake it in another. 'Practically,' says the Reviewer, whose opinions have been already quoted, 'in a pauperised district, where the labourers' wages were composed partly of wages and partly of allowance, the married man had no more free-will as to the parish in which he should reside, the master whom he should serve, or the subsistence which he and his family should receive, than the horse which he drove. In parochial language, he belonged to the parish in which he had his legal settlement.'

There can be no doubt that the condition of the working-classes in England during the prevalence of this system was a species of slavery. The system lasted with little alteration for nearly forty years; but long before that time its moral evils, and the enormous increase of expenditure which it demanded, had excited great alarm, and made England, with regard to this particular part of its domestic polity, a wonder to neighbouring nations. The sum raised for poor-rates in 1776, while the workhouse system of 1723 was still in operation, was only £1,720,316; in the three years after the passing of *Gilbert's Act* (1783-4-5), it averaged £2,167,749. But the average of 1801-2-3 was £5,348,205; in 1818, a year of scarcity, it reached the enormous sum of £9,320,440; and even in the fair seasons of 1830, 31, 32, and 33, it was above eight millions. This was an increase far exceeding that of the population, and the more alarming, as it took place during a period of progressive national prosperity. Almost everywhere it pressed very severely upon the property of the country, and in some places had even caused property to be abandoned, the rates exceeding all that could be derived from the land.

The evil being generally felt and acknowledged, a royal commission was issued in 1832 for inquiring into it, in order that parliament might apply a remedy. The following, taken from the second edition of M'Culloch's 'Statistical Account of the British Empire,' is a condensed summary of the report which this body drew up, after a careful investigation conducted throughout

## POOR-LAWS.

every part of England and Wales:—That wherever the expenditure had most increased, there also the industry of the labourer had proportionally degenerated, because in such places subsistence from the poor-rates was more easily obtained than by labour. That under such influences his prudence and thrift were discarded, because they could, with the utmost success, only secure for him, by present sacrifice of enjoyment, the same future advantages of which the pariah held out a prospect without the necessity of any sacrifice save that of independence. That his sobriety and temperance were thus left without encouragement, and, on the other hand, exposed to the temptations of comparative idleness, and the facilities for the indulgence in idleness and intemperance which always accompany the growth of pauperism: his respectability of demeanour was now useless, as respectability of character ceased to be relied on as a means of securing employment, itself no longer an object of desire. That in the same proportion as he became independent of regular industry, did he also become independent or regardless of the comforts of his home—comforts which are indispensable to the labourer after a day of toil, but are rarely sought or valued as a change after a day spent in idleness or dissipation.

It was also observed that, as the habit of pauperism increased, the standard of subsistence of the labourers in the district was lowered, the relief never being sufficient of itself to maintain the pauper independent of all work; and yet, by rendering him partially so, constantly tempting him to forego that further portion of comfort which was attainable only on the comparatively hard terms of earning it by the sweat of his brow. The standard of the pauper's subsistence being once lowered, that of the industrious labourers amongst whom they lived, and who occasionally felt the effects of their competition, fell also. Where the system prevailed of allowing relief in aid of wages, there the operation was immediate, as all the labourers were at once pauperised, being equally exposed to the effects of a system which left all industry, beyond a certain point, without its reward, and therefore without a visible object. While these influences were destroying the industry and morality of the able-bodied labourers, the bastardy-law was holding out encouragement to female unchastity, in the way of a money allowance for each bastard, which, by its amount, of itself elevated her condition in proportion to the number of her spurious offspring, rendering a mother of several bastards better off than she would have been as a mother of as many lawful children, and securing her a dower which usually tempted some man to marry her; while the same law, by subjecting the supposed father to punishment, often subjected him, at the woman's discretion, to the alternative of marriage or a jail—the former of which was generally chosen as the least present evil. Under these influences female chastity had in many districts so far ceased to be valued as a virtue, that not only the woman herself, but her parents and her husband seemed, where the law had had its full uncontrolled effect, to have become indifferent to it.

The evils of the system were not confined to the paupers, but unhappily extended to all who had to administer the law. So large a fund as between seven and eight millions, administered without any practical responsibility, naturally tempted the cupidity of the officers through whose hands it passed. The office of overseer was therefore generally sought by a class of small farmers and tradesmen, to whom the office must have been most burthensome had it been discharged gratuitously as the law provided. It was found that the overseers were usually appointed, in places where the evil had reached a great height, not from the class of the *substantial householders* of the pariah, as the statute of Elizabeth requires, but were usually needy persons, to whom the indirect advantages of the office were important, and who were helped into the office by the efforts of persons similarly interested, either as tradesmen of the pariah, or as owners of the dwellings which the

paupers inhabited, or in other ways, more as receivers, directly or indirectly, of the rates, than as rate-payers. The spirit of the enactment, 45 Geo. III. c. 54, § 1, which provides that no contract for the lodging, keeping, or maintaining the poor, or for taking the benefit of their work for their better maintenance, shall be valid, unless the person with whom it is made shall be resident within the pariah, was fully carried out in practice in nearly the whole of the 15,000 parishes and places separately maintaining their own poor—every tradesman of the pariah, and every employer of labourers, being bribed to maintain whatever system the vestry adopted, by a share in the profitable supply of the pariah poor, or by the payment of a part of the wages of his labourers in the shape of relief to them out of the rates. The refractory parishioners were constrained to acquiesce, on pain of losing these and similar advantages, which, being withdrawn or denied, left to them only the obligation of paying those rates. To secure, moreover, the full operation of this system, the pariah was not permitted to deal elsewhere for any commodity with which any parishioner could supply it, and was thus usually confined to the worst market for the goods it purchased, in the same manner as, by the laws relating to labour, it had been cut off from the supply of other labourers while any within its own bounds remained unemployed.

The evidence seems also to prove that the functions of the magistracy had almost invariably ceased to be applied to the objects for which they had been created. The magistrates of counties were usually too dispersed, and too little immersed in the actual business of the several parishes, to avail themselves of the advantages which the overseers and the other more immediate administrators of the system derived from it. The magistrates of corporate boroughs, towns, and cities, were, however, in many instances found to be not less rapacious or ready to apply the administration of the law to their pecuniary profit or direct advantage than the parochial officers. But although the magistracy must generally be acquitted of having sought to derive an immediate pecuniary advantage from the administration of the poor-laws, they were none the less ready to pervert the law to purposes utterly at variance with its original intention and with the prosperity of the community. Very many of the magistrates, influenced by benevolent intentions, were ready on all occasions to admit the claim of the pauper, and to compel overseers to administer relief when they inclined to refuse it: such magistrates were constantly resorted to by paupers in preference to others who more vigilantly examined the grounds of their claims; and a reputation for being the *poor man's friend* was easily earned by the lavish and immoderate expenditure of the fund of the general rate-payers. This reputation was found to be useful in many ways, and was thus sought for political purposes, or for the attainment of local power, or for the mere gratification of vanity, by many magistrates, whose sympathy for the pauper would never have been excited if it had been incapable of being gratified at the expense of the rate-payers. When it is considered that the county magistrates lived for the most part in the midst of a population of willing paupers, and the means of annoyance which the latter possessed, if they found occasion to use it, against an obnoxious person, is also borne in mind, it is not to be wondered at that the magistracy generally purchased the good-will of their neighbours by sacrificing the interests of the rate-payers, whom they never had personally before them, and who were very inadequately represented by the overseer, whose interests were too frequently found to coincide more with the demand of the pauper and the inclination of the magistrate than with the strict line of his duty.

In consequence of the report of the commissioners, an act was passed in August 1834 (4 and 5 Will. IV.), usually called the *Poor-Law Amendment Act*, by which these monstrous evils were for the most part extinguished, and a return made to the just principles

by a few individuals. As a proof of the public feeling on the subject, we present the following extracts from the two leading Reviews; and all who know anything of political parties and their connections in this country, will be ready to own that no better means could be fallen upon:—The 'Edinburgh Review' of March 1831, after remarking that the intended benevolence of the allowance system had proved a 'bitter curse'; that it robbed the rate-payer to pay farm-labour, and enslaved the labourer, adds, that '*its abolition is the imperative duty of the legislature.*' We say abolition, for nothing short of this can be of any material service.' The 'Quarterly Review' of January 1834, after making an extract from the part of the Commissioners' Report drawn up by Mr Chadwick, says—'It is gratifying to us to find the immediate abolition of the allowance system here insisted upon so strongly. We might have wished this suggestion to have taken precedence of every other, as being *by far the most important and indispensable of any.* . . . An improvement in the management of workhouses is highly necessary. *They should be made places of strict confinement and hard labour to the able-bodied,* with a moderate diet, and a total denial of all indulgences, in order to render a residence within their walls as irksome and distasteful as possible, and the last resource of those only who cannot, by their utmost exertions, obtain a maintenance.'

With regard to the impotent poor, this act rather increased than diminished the liberality of the arrangements, while it made several other considerable improvements. The great class of adult persons who, from old age or infirmity of body, are wholly unable to work, were to remain, as before, entitled to a support by means of out-door allowances. Of destitute children, those unlikely, from natural defects, to be able to win their own bread, were provided for by out-door relief; those, on the other hand, who were likely to prove useful members of society, were taken in charge, and reared in separate establishments, where their education and training for industrious callings were particularly cared for. Judicious provisions were also made for their being ultimately set afloat in the world as apprentices. With regard to illegitimate children, several former provisions of evil tendency were annulled; and it was provided that no regard should be paid to them till they became actually chargeable upon the parish, when relief should be extended through the mother, she being in this respect treated as a widow. Persons unable to support themselves through accident, or from sudden and dangerous illness, were to receive temporary relief, and to have all necessary medical attendance. Insane paupers were to be placed in proper asylums at the expense of the public.

The provisions for *able-bodied* claimants formed the most important part of this act, as indeed it was in this department that the abuses of the old system were the most glaring. The main feature of the new arrangements was the erection of workhouses by unions of parishes, where relief should be offered to able-bodied claimants, on the condition of their giving their labour in return, and submitting to the rules of the establishment. This was only a revival of the *test* applied by the act of 1723, the object being to check applications for relief from the slothful, and to throw upon the able-bodied in general the duty, which is everywhere else the lot of free labourers, of finding employment for themselves. The new law contemplated that the food and accommodations of the workhouse should be good and sufficient, but yet not quite so good as those which the free labourers of the district could obtain by their own exertions; so that it might, upon the whole, be more agreeable to the able-bodied man to work for himself than become chargeable. At the same time, it being acknowledged that a change from one system to another could not be expected to be suddenly effected without some degree of hardship, provision was made

machinery for the local administration of the poor-laws. The rate-payers elect for each union of parishes a board of guardians, each rate-payer having votes in proportion to his property, and the proceedings of these boards were under the control of a central board, composed of three commissioners appointed by the crown. (See next page.) Under the chief commissioners there were twelve assistant ones, each of whom had the inspection of a particular district.

Gradually, under the operation of the Poor-Law Amendment Act, the greater part of England has been formed into unions (now 592), each under a board of guardians, and each provided with a workhouse. In the first year of the new system the commissioners issued a general order, prohibiting relief in money to the able-bodied in the employment of individuals, thus throwing their entire support upon their masters. In the second year they began, in a cautious manner, in obedience to the spirit of the act, to put a stop to out-door relief to the able-bodied—meaning labourers who, with their families, are in health, but excepting widows with young children. By these means the expenditure upon the poor was reduced from £7,511,219 in 1834 to £4,044,741 in 1837, or almost to one-half. Since 1837, the expenditure has again been on the rise, and in 1840 it was £5,110,683. In 1847, the number of paupers (including children) relieved in England was 1,721,350, or about 1 in 9 of the population. Of these, 265,037 received in-door relief; 1,456,313 received out-door relief. The amount received was £7,117,352; of which £5,298,787 was expended on the poor, £899,095 on in-door maintenance, and £3,467,960 on out-relief. In 1848, the number of paupers (exclusive of children, who number about 300,000) was 1,626,201; of whom 1,361,061 received out-door, and 265,140 in-door relief, at a total cost of £6,180,765!

The first effects of the stop put to the allowance system were most surprising. The so-called surplus population—the hordes of unemployed men who had required to be partially or entirely sustained by the parish funds, who had been condemned to stand in the parish pound for days, and spend half their lives in a kind of idleness in the parish gravel-pits—disappeared as if by magic. It was found that, left free to seek employment where it could be had, and furnished with the usual motives to exert their industry, they all obtained employment. On this subject the earlier reports of the commissioners gave some valuable information, showing how delusive must have been those views which held forth the population as redundant, and as needful of artificial support. The whole evil seemed to be one of derangement. Once disengaged from the trammels which confined men to certain spots of ground, and put a bounty upon their remaining idle, the people quickly fell once more into natural arrangements, and there was an independent maintenance for all. To quote an able writer in No. 74 of the 'Edinburgh Review':—'When the bonds which confined them to their parishes were broken, they distributed themselves where their services were most wanted. When they were allowed the free disposal of their services, they endeavoured to make those services valuable. When the application of more efficient labour increased the employer's returns, and at the same time reduction of rates diminished his out-goings, he had a larger fund for the purchase of those services. The redundancy vanished with its causes. The able-bodied pauper is the result of conventional error and art. He is not the natural offspring of the Saxon race. Unless his pauperism is carefully fostered by those who think it their interest to preserve it, he rapidly reverts to the *normal type*—the independent labourer.'

The union workhouses are in general remarkably well-arranged establishments. The food, both in quality and quantity—the accommodations of all kinds—the moral discipline and order, are in general all that

the humane and the enlightened could wish. The arrangements for the education of the young are particularly worthy of commendation. Workhouses are for the most part occupied only by some portion of the aged poor, and by young children. Though held open for the reception of the able-bodied under any exigency to which they may be presumed liable, they are rarely resorted to by such persons, partly because the labour-market being freed, there is in general no lack of means for an independent subsistence, and partly from the natural dislike to a life of restraint. One regulation of these houses may be supposed to have operated powerfully in keeping idle married men at a distance from them. In most instances they are not allowed to live in the same part of the house with their wives. Partly this was needful for the sake of order, and to avoid sundry gross evils which flourished under the old system. Partly it is owing to a principle laid down by the commissioners, that a pauper is not entitled to be in this respect on a level with the man who works independently for himself and his family. This regulation attracted much clamour and vituperation, and perhaps it would have been better, at least in point of expediency, not to have had it introduced.

The new law has now been in existence for fifteen years, during which period it has undergone various minor modifications—chiefly affecting the administrative machinery, the subject of medical relief, the care of pauper lunatics, the relief of vagrants, the law of settlement, the education of pauper children, and other improvements which the condition of the country, for the time being, has rendered expedient. The main alterations which it has undergone are under the provisions of an act (10 and 11 Vict., chap. 109) passed 17th December 1847. By this act the commissioners are superseded by a controlling board, consisting of four members of the government *ex officio*, and certain other commissioners appointed by the Queen in council. The inspectors are also vested with more extensive powers; visitors of workhouses are appointed; annual reports are ordered; and the law compelling the separation of man and wife dispensed with after the parties are sixty years of age.

Excellent as the measure has been in its main features, and though it has redeemed the English labouring-classes from a kind of slavery, it has been the subject of an outcry of the most violent character. This is partly traceable to those who profited by the abuses of the old system, partly to an ignorant sentimentalism, and partly to the arts of politicians, who, by appealing to the prejudices of the masses, make the subject a handle for their selfish and party purposes. If the system has been violently attacked, it has also been as warmly defended; and in the midst of so much scrutiny, the disinterested may rest assured that no very flagrant abuse can be long committed by those who administer its provisions, or suffered by those to whom its provisions are administered.

ARRANGEMENTS RESPECTING THE POOR IN SCOTLAND.

For a long time there were no poor-laws of any sort in Scotland. The poor were left totally unregulated, and matters became at length insufferable. The whole country was overrun with hordes of sturdy ruffians, who lived at free quarters upon the industrious, a farmer having not unfrequently to provide food for a score or two of able-bodied 'sorners' in the course of a day. These vagabonds, often living in incestuous connections, held routs and revels by thousands in the mountains, and attended punctually at all country fairs, weddings, and festivals. Legislation on this subject opened with three acts passed in the reign of James I. in 1424, which conferred a right to beg with 'takinnes,' on the same classes of paupers who subsequently obtained a right to relief by 1579, c. 74. This last statute, with a proclamation of the Privy-Council, was, until lately, the only authority for a compulsory poor-rate in Scotland. It consisted of two parts: One ordained 'strong and idle beggars' to be scourged and

burnt through the ear with a hot iron; and if caught again at their vocation after sixty days, to be put to death. The second conferred a right to parochial relief on certain parties, whom it designated as 'aged, pure, impotent, and decayed persons,' 'quhilk of necessitie mon live bee almes.' Some subsequent acts made provision for employing able-bodied beggars in common works, and ordained the building of correction-houses, under heavy penalties on the burghs disobeying; but not a single correction-house was ever built, and that part of the law became obsolete. The last proclamation of the Privy-Council, March 3, 1698, completed the fabric of the old poor-law, which was superseded by the Poor-Law Amendment Act of 1845.

There were many disputes in respect to the classes of poor which were vested with an absolute right to require relief under the old law. The general understanding was, that the Act 1579 only included all who were permanently disabled from age, sickness, or infirmity from gaining a livelihood by labour, destitute children under fourteen years of age, insane persons, and idiots. In practice, also, destitute widows, with several young children, generally received some small modicum of relief; those who were temporarily destitute or infirm were understood to have no legal claim on the parish, but might be relieved at the discretion of the authorities. Speaking in very general terms, a settlement was acquired by three years' continuous residence in a parish. Wives had the settlement of their husbands; legitimate children of the father, and illegitimate children of the mother. When there was no other settlement, recourse was had on the parish of birth.

Where there was a legal assessment, the general purpose seems to have been to tax every man in the ratio of his means. Accordingly, originally the parochial board stented every individual's proportion according to their own estimate of his ability; and if he demurred, he had to lay bare his whole affairs before officials bound to no secrecy. This was so burthensome, that a rough-and-ready criterion was adopted wherever it was possible. In rural parishes, half the assessment fell on the heritors, according to their real or valued rents, and half on the other householders, in whose case the rent of the houses occupied was generally made the criterion. In burghal parishes the value of the tenements was the criterion; and sometimes the assessment was laid altogether on the tenants, sometimes altogether on the proprietors, and sometimes half on the one and half on the other. In mixed parishes the grievous plan of stenting seems to have been continued. Often, however, the assessment was entirely voluntary, and in the majority of cases there was no assessment at all. Relief was given from the collections at the doors of the parish churches, half of which had to be paid into the general fund, the other half remaining at the disposal of the kirk-session.

The administrators of this fund were—in burghal parishes, the magistrates; in landward parishes, the heritors and kirk-session; and in the latter, when vacant, the heritors alone. These bodies had almost despotic power over the pauper—the mode and extent of relief being in practice at their discretion. The only authority competent to review their decisions was the Court of Session; and it refused to interfere with the amount of relief given, unless it was altogether illusory. On coming into that Court, the pauper, if an agent of the poor reported that he had a probable cause of action, was put upon the poor's roll, and had counsel assigned to him. Practically, the parochial boards could do as it seemed good to them: there was no central administrative board of any sort.

This state of matters gave rise to great discontent and many complaints, and ultimately a commission of inquiry was instituted, whose report filled eight quarto volumes, and contained a vast amount of interesting information. This report was laid before parliament in May 1844. It presents a very vivid picture of the state of the paupers throughout Scotland at and previous to that date. Their condition

varied much in different parishes and in different parts of the country. In Glasgow and some other places they were comparatively well off; and even in districts where the allowances were wretchedly inadequate, they were not so utterly miserable as they seemed, when considered in reference to local circumstances and the condition of the independent poor. Still the operation of the law was far from satisfactory. To take, first, the Edinburgh parishes: the weekly allowance to a widow with one child was 1s.; the very highest to a widow with six children was 3s., which was considered extraordinary; to a married couple the allowance was at the utmost 7s. 6d. in six weeks. The house was overcrowded; there was no classification of the sexes; and the deaths for five years averaged 80 every year out of 420 inmates. In St Cuthbert's, a widow with two children received 1s. a week. In the Highlands things were much worse. In Shildag in Rosshire the general yearly allowance was 5s. to 6s.: in Kirkwall, a widow with children received 2s. 6d. a quarter: in Poolewe, a widow with four children received from 4s. to 8s. a year; and in Gairloch, 2s. 6d. to 5s. a year. Often the whole sum annually divided in a parish was two or three pounds, as in Kilchonan in Inlay. Of course begging was the natural and necessary supplement of the allowance. In many instances the pauper made a livelihood by continually roaming in quest of a settlement that never came, and this imposture had become intolerable. Maniacs were allowed in general to rove as they chose, or boarded in unlicensed and unregulated houses. In short, an immediate change was necessary, and the commissioners reported to that effect.

The Poor-Law Amendment Act was the consequence of this report. Its great feature was the creation of a Board of Supervision, 'to inquire into the management of the poor in every parish and burgh of Scotland,' and to report annually to the Home Office on everything connected with the state and management of the poor. It was to fix the number and qualification of the elected members of parochial boards; divide parishes into wards, and allot to each its proportion of representatives; dismiss inspectors and medical officers; and exercise other powers of the most extensive kind. The act sanctioned three modes of assessment: (1), One-half on owners, and the other on tenants or occupiers of lands and heritages, rated according to the annual value of such lands and heritages; (2), One-half on such owners according to the same rate, and the other half on the whole inhabitants according to their means and substance, other than lands and heritages in Great Britain and Ireland; and (3), The whole as an equal per-centage on the annual value of all lands and heritages, and on the estimated annual income of the whole inhabitants from means and substance, other than lands and heritages within Great Britain and Ireland. The act also sanctioned the continuance of any other mode of assessment established by local act or usage.

In the event of no legal assessment, the old administrators were to remain. In assessed burghal parishes the boards were to consist of three elements: (1), Four members sent by the magistrates; (2), Four by the kirk-session; and (3), Members elected by the rate-payers. Each owner of heritable property under £20 of annual value was to have one vote; from £20 to £40, two votes; £40 to £60, three; under £100, four; under £500, five; above £500, six. Occupancy and means and substance were to entitle to votes, rising in number according to the same gradation. Parties might vote both on ownership and means and substance, but could not have more than six votes in all. In rural assessed parishes, the boards were to consist of four elements: (1), Owners of heritable property of the yearly value of £20 and upwards; (2), Magistrates of any royal burgh within the parish; (3), Not more than six members of the kirk-session; (4), Members elected by owners of heritable under £20 annual value, who are to have one vote; and by tenants and occupants, and persons assessed on means and substance, who are also

to have one vote under the same annual value, and to have more votes according to the gradation we have already specified. No person was to be rated on means and substance under £30 a year. In assessed parishes, the whole of the church-door collections were left at the disposal of the kirk-sessions.

On an application for relief, the inspector was ordained to return an answer within twenty-four hours. If the applicant were entitled to relief, it was to be instantly given, recourse being retained against his relatives, if legally liable, and against the parish of his settlement when found. On refusal, the sheriff was to be applied to to enforce the claim; and he might also grant interim relief till the question was decided. He was not, however, to decide in regard to the adequacy of relief. If there was any complaint of that kind, the complainant was directed to apply to the Board of Supervision, who might either reject the complaint, in which case no other court was competent to take it up; or approve it by a minute, which had the effect of opening the doors of the Court of Session to the pauper, and putting him on the poor's roll. Irish and English paupers were made removable, when they had acquired no settlement in Scotland, by an order of the sheriff or of two justices, at the expense of the complaining parish; and if they returned to the same parish, might be imprisoned with or without hard labour for not more than two months. Desertion of children was made punishable by fine or imprisonment with or without hard labour—payment of the fine to be enforced by imprisonment. The parochial funds might be applied to provide medicines, medical attendance, nutritious diet, cordials, and clothing to the paupers, and education for the pauper children. Boards might also subscribe to public hospitals or dispensaries, and might erect poor-houses when the population of the parish or combination of parishes exceeded 5000.

Some time after the passing of this act, the question of the right of the able-bodied unemployed and of their children to parochial relief was set at rest. The cases were those of the inspectors of the parish of Gorbals against William Lindsay, who applied for his children, and the inspector of Glasgow parish against McWilliam, who applied for himself. The circumstances were in the most favourable form for the paupers, whose allegations were all admitted; and the whole court was consulted, when it was nearly unanimously found that an able-bodied man, utterly destitute, and unable to find employment, had no legal claim against the parochial funds, either for his own relief or that of his children in pupilarity. Of course parochial boards might relieve such parties at their discretion.

The Board of Supervision, appointed under this important act, entered on its duties on the 4th of September 1845, and gave in its first annual report in August 1846. At that date all the parishes had elected inspectors, and more or less willingly provided funds. Reports were also presented in August 1847 and August 1848. A few statistical facts will show the working of this statute—

In the year ending 1st January 1836, the sum expended on the poor did not exceed £171,042: in the year ending 1st February 1846, it amounted to £295,232, an increase of £124,190 in ten years: in the year ending 14th May 1847, it was £483,915; and in the year ending 14th May 1848, it was £544,334.

The number of poor on the rolls on 1st February 1845 was 63,070, or about 1 in 42 of the population: on the 1st February 1846, it was 69,432, or about 1 in 38: on the 15th May 1847, it was 74,161, or about 1 in 35.3. The total number of paupers of all sorts relieved during that year was 146,370, or about 1 in 17.8 of the population. On 14th May 1848, the number of poor on the rolls was 77,732, or 1 in 33.7 of the population. The total number relieved during that year was 227,647, or 1 in 11.51 of the population.

At August 1848, 14 poor-houses, 5 of which were temporary, were in operation in 14 parishes, the population of which was in all 548,745. The houses were

## POOR-LAWS.

capable of accommodating 8198. Plans had been approved of by the Board for 8 new poor-houses, and 2 additions, representing accommodation for 2910 more paupers. Five other parishes had resolved to erect permanent poor-houses.

The whole sum of £544,334, 7s. 6½d. expended in the year ending 14th May 1848, was thus accounted for:—Relief of poor on the roll, £491,385, 7s. 5d.; *casual* poor, £53,884, 7s. 7½d.; medical relief, £30,339, 12s. 5d.; management, £42,038, 18s. 4½d.; litigation, £5719, 6s. 11½d.; poor-house buildings, £10,971, 12s. The whole sum derived from church-door collections was £14,898, 2s. 2d.—of which £8462, 18s. 7½d. was stated to have been expended for the relief of the poor.

Under the old system, parochial boards were under no obligation to send lunatics to licensed asylums, which gave rise to gross abuses. That was altered; but the Board of Supervision was much hampered by the want of accommodation in the asylums. The total number of insane or fatuous paupers in the year ending May 1846 was 3480. The Board examined into 2008 cases where the patients were not confined; ordered 36 to be immediately removed to some madhouse, and dispensed with the removal of 1969 on the ground of insufficient accommodation, harmlessness, or the like.

At the date of the first report, arrangements were in progress in Edinburgh, and also in Glasgow, to institute Industrial Schools for the pauper children, and at present the subject of pauper education is exciting more and more attention. In parishes where there are no magistrates or police commissioners, the boards are appointed to carry out the provisions of the Act 9 and 10 Vict. c. 96, for the removal of nuisances. They had also important duties under the Temporary Health Act; and the legislature manifests a disposition to render them bodies of great future importance.

There still remains, however, a great deal of dissatisfaction with the working of the present poor-law; and a number of delegates from the various boards met in Edinburgh lately to discuss the subject. One topic of complaint was the facility with which Irish and other paupers, not Scotch, obtained interim relief, and also a permanent settlement. Glasgow and other towns were grievously burthened in this way. Some of the heavily-rated and poorer parishes also were anxious for a national settlement, and some of them wished combination with richer neighbouring parishes. In fine, judging from the present tone and temper of the country, the existing system is destined shortly to undergo very considerable alteration.

### ARRANGEMENTS RESPECTING THE POOR IN IRELAND.

In Ireland there was, till a recent period, no systematic provision for the poor, but the country was by no means destitute of institutions designed for their benefit.

Legislative enactments had progressively, during the last century, established county infirmaries, dispensaries, lunatic asylums, houses of industry, and receptacles for destitute infants and old people; and similar institutions, together with schools, lying-in hospitals, houses of refuge, and mendicity houses, had been set on foot in various places by private benevolence. But while much was thus done for the alleviation of temporary and casual distress, there was a mass of mendicancy, and an amount of general suffering from occasional famine and consequent epidemics, which made Ireland singular among the countries of Europe. It was calculated that, out of a population of between seven and eight millions, upwards of two millions were in a state not much short of permanent mendicancy. The great bulk of the people being an agricultural peasantry, living on small patches of land, and depending mainly on the potato crop, a failure of that product was attended with wide-spread misery, invariably followed up by destructive fevers. The epidemic of 1817, which was the effect of the failure of the crop of 1816, affected a million and a-half of persons, and carried off 65,000. The people, moreover, having no resource but their little patches of potato

ground, landlords found that they were rapidly losing all power over their property. Desperation made the tenants cling to their ground with a pertinacity which nothing could overcome. A common danger having united them in one common cause, the forcible ejection of a tenant was resisted by one and all, or, if effected, it was sure to be savagely avenged. Practically, the tenant was able to remain on the ground as long as he chose, without much regard to the payment of rent, unless his *good-will* was purchased either by the new tenant or by the landlord. The inconveniences experienced in consequence of the bulk of the people being thus always on the verge of destitution, and without any resource when they reached that point, had become, in addition to those of actual mendicancy, so grievous, that a poor-law began to be contemplated as necessary for Ireland; and in 1833 a royal commission was issued for an inquiry into the subject.

In consequence of the report of this body, an act was passed (1 and 2 Victoria, c. 56) for the introduction of a modified poor-law into Ireland. In the principal arrangements, those adopted in England under the Poor-Law Amendment Act were followed; and the general superintendence was confided to the same commissioners. 'The chief peculiarity of these laws,' says Macculloch, 'is that relief under them is administered solely in workhouses; and thus they differ from the Scotch poor-laws, under which workhouses have scarcely been made use of at all, except in a few large towns; and from the English poor-laws, which were intended by the legislature to be a mixed system of relief to the able-bodied in workhouses, and of relief to the impotent poor, partly in workhouses and partly at their own homes. They differ again from the English and Scotch poor-laws in this, that while in England all destitute persons have a legal right to relief, and in Scotland all destitute impotent persons have a similar right, in Ireland, on the contrary, no individual was intended to have a legal right to relief; but at the same time, whether able-bodied or impotent, he may equally receive relief in workhouses, provided he is destitute.' Under this law, which has already undergone several modifications, the expenditure for the poor in Ireland for the year ending 1st January 1846 was only £316,026, and the number of paupers receiving in-door relief, 43,293. By December 1848, partly from successive failures of the potato crop, and partly from the unsettled state of the country, the number of in-door paupers had increased to 185,825, and the out-door to 893,421. During that year the sum expended was £1,855,389—an excess of more than £200,000 above the rates collected. To meet this state of matters is the object of the Rate-in-Aid bill, by which the whole country is to be assessed, for the purpose of making up any deficiencies that may occur within the poorer and more heavily-burthened unions.

### GENERAL OBSERVATIONS.

Poor-laws are, after all, only an expedient for meeting an evil partly inherent in human nature, and partly the consequence of its erroneous moral and political condition. Were all born equally sound, and were all so instructed and so placed socially that each man realised a reasonable sum for his labour, and was disposed to make a proper use of his gains, there would be no need for poor-laws. Such conditions not existing, this expedient is unavoidably called into use, and we must not be surprised that, as one designed to meet great evils, its own operation is attended by less ones. By far the worst effect of poor-laws is the moral degradation which they produce in those for whose benefit they are established. The man who has to ask for public relief to his necessities, loses from that moment the self-respect on which much of his virtue depends. A fatal lesson is taught him—that his wants may be supplied without his own exertions—and the motive to an independent and industrious course of life is greatly shaken, perhaps destroyed. This is itself an evil of such serious magnitude, that it forms with

recent period, and still is the predominant sentiment of a large portion of society in that country. It is an objection which we, for our own part, would have difficulty in overcoming, if we did not see around us the awful effects which an inadequate provision for the poor works in the present condition of society. Unquestionably nothing but a consideration of the horrible inhumanity, and the extreme dangers to the common weal, which are inseparable from the neglect or repulse of pauper claims, could excuse the deterioration which we unavoidably effect in a man's nature, by giving him that for which he has not laboured.

Another great evil of poor-laws is, that they take away part of the fruits of industry from those who have legitimately acquired them, and bestow them upon the idle. Industry is by this means discouraged, and sloth and improvidence are in a proportionate degree fostered. In England this had reached to an enormous height, and even now the abstraction of six millions from the gains of the industrious must operate very seriously in retarding the progress of the country. It is, however, a tax unavoidable in present circumstances, if we would escape more serious evils.

While a reasonable doubt can scarcely be entertained as to the propriety of both succouring the helpless and offering a modified provision to the able-bodied in a needful state, it must be equally clear that the more that habits of foresight and self-dependence are propagated in the country—the more that all-sustaining moral influences are diffused through it—we may expect to see the less need for poor-laws. Although there are upwards of thirty-two millions in savings-banks, and benefit societies are widely spread, still the great bulk of the labouring-classes of this country live from hand to mouth, without any store whatever on which to fall back in the event of sickness or an occasional lack of employment. This is a preposterous state of things. What is to be expected of a people, the great bulk of whom are contented to live with only a little accident between them and a state of dependence on private or public bounty? Sickness is what all are liable to at all times; failures of employment take place at frequent intervals everywhere. There surely might be some better provision against such contingencies than a public provision, which makes the recipient a degraded man for ever. Individuals might be induced, by an improvement of the moral agencies of the country, to do much for the securing of their own independence; and the remainder of the required provision might perhaps be obtained by systematic contributions from the labouring-classes towards a common fund, from which succour could never be a degradation, seeing that they had themselves created it. Proposals of this kind are apt to strike the mind unfavourably, from their being new; but the position at which this country has arrived is in some degree new, and accordingly calls for measures of a different kind from what we are accustomed to contemplate. Certainly, while only the expedient of poor-laws is adopted, the community can never be inspired, in all its departments, with that manly and independent feeling which is the inseparable associate of all the other virtues, and the great distinction between the freeman and the slave.

#### LIFE-ASSURANCE.

Life-assurance, in its ordinary character, is a means of securing, by a present payment in full, or by an annual payment, a sum to be realised after the decease of the party. It is obvious that, to many persons, the having this in their power is of great importance. To none is it so important as to individuals in the middle walks of life, who, for the present, are perhaps able to maintain their families in comfort, but being unable to accumulate a large surplus capital, cannot be sure that, in the

of providing for those in whom they are interested. With a certain annual sum laid aside from a professional income, or from the profits of trade, such a person can make sure that, though death cut him off abruptly, his widow and children will have something to look to, either for an entire maintenance, or to aid in enabling them to gain one for themselves. By the same means an individual, possessing an entailed estate, can make provision out of its current rents for those younger and female children, who, at his death, would cease to be benefited by it. An individual, also, incurring a risk in behalf of another, or having a large claim upon him in the form of debt, can insure upon the life of that person such a sum as would be sure to cover all loss in the event of that person's sudden death. There are many other circumstances in which life-assurance may become highly beneficial; but its chief utility lies in securing a certain sum to helpless persons, in the event of the decease of those on whom they depend.

The principle on which life-assurance mainly rests is one which it has been reserved for modern times to discover—namely, that while the duration of the life of a single person is of all things the most uncertain, it is possible to ascertain, with tolerable accuracy, how many of a *multitude* of persons, of a particular age, will die within next year, how many in the second year, how many in the third, and so on. The medium or average gives what is called the *expectation of life* for each person of the set. A certainty, in short, is attained on this proverbially uncertain subject, when we take a great number of persons, and consider them with regard to the circumstances in which they live. It is found, for instance, that of 100,000 persons, aged 52, residing in this country, the number who will die before another year has elapsed will be about 1521, or rather more than one and a-half per cent. Supposing that these 100,000 persons were to associate for the purpose of making sure that the widows or other heirs of all those who died within a year should have £1000; it would only be necessary in that case for each person to contribute as much to a common fund as would make up £1,521,000, or a thousand times 1521; that is to say, each would have to pay in £15, 4s. 2d. It is clear that those who died, or their heirs, would profit to the extent of £984, 15s. 10d.; but without injury to those who survived, for these also had their chance of gaining, for which it was but fair that they should pay. This would be a simple transaction in life-assurance, and may serve to convey an elementary idea of what life-assurance is, though in practice the transactions are usually of a somewhat more complicated kind.

An assurance is rarely transacted for a single year. The object of most is, to pay a certain sum each year, as long as they live, in order that a sum may be realised at their death. Assurers are also of various ages; the young have the expectation of longer life than the old. It therefore becomes proper that they should pay less than those more advanced in life. Indeed there ought to be a payment appropriate to each particular age; and this, accordingly, is the case. Another point calls for particular consideration. The payments being made, not to clear off one year's claims, but to make good a sum many years hence, large funds become accumulated, and upon the improvement of these much depends. If a high rate of interest is obtained, the funds experience a rapid increase, and the less payments are required to effect insurances. If, on the contrary, the interest realised be small, the insurers require to make their original payments so much the higher.

Life-assurance is effected in this country either in offices established by joint-stock companies, who look to making a profit by their business, or by mutually assuring societies. The former are shortly called *proprietary*, and the latter *mutual* offices. Offices of the first kind are usually held by a joint-stock copartnership, with a large subscribed capital; and the chief advan-

## LIFE-ASSURANCE.

tage which they hold forth, is the ample security for all claims presented by the capital, and the respectability of the shareholders. In the case of a mutual office, there is only, it may be said, an association of customers, each of whom is concerned in insuring his neighbour. In this case, however, all surpluses, instead of going into the hands of a trading company, remain the property of the insurers, and are liable to be divided amongst them. For a long time the business was conducted almost exclusively by companies; but it was at length seen that all desirable security was to be obtained on the association principle; and for some years the system has been advancing much more rapidly than the other. In various instances, companies have scales of charges allowing of a participation in surpluses; and these are usually called *Mixed Proprietary and Mutual Offices*.

The existing British offices are upwards of 120 in number, most of them of recent origin. The oldest is the Amicable of London, established on the mutual principle in 1706. At the time when it was set up, no calculations as to life existed; and the conductors were accordingly obliged for many years to proceed in a great measure at random, charging the same premiums or annual payments for all ages under forty-five! The rates charged by the several offices are very various, but in all cases they have been found as yet sufficient for the risks. In most instances the companies divide large profits, while the mutual offices have realised equally large surpluses, which they have divided amongst the insurers, in proportions according to the sum assured and the duration of the insurance, or upon some other principle which the insurers may deem preferable.

Life-assurance grew up in the last and present centuries amidst such an imperfect knowledge of the data on which it depends, that there is little to be wondered at in the great variety of rates charged by the different offices. These data are now much better understood, and it has become possible to arrive at a comparatively close estimate of what charges are really required from an individual, in order to make good a sum at his death for the benefit of his survivors. There might be greater closeness still, if the laws of mortality, now so well ascertained, were alone concerned; but the rate of interest upon money also enters into the calculation, and this, as is well known, is liable to frequent fluctuation. Loose as the matter thus remains in some measure, enough is ascertained to admit of an approximation being made to something like a standard for the conducting of this important branch of business.

The rate of mortality and the rate of interest upon money are the two principal data on which life-assurance practically depends. We shall first consider

### THE RATE OF MORTALITY.

Tables of mortality are founded on the assumption that human life is of a certain average endurance; and by means of them we estimate the number of deaths that may be expected among a given number of individuals, from the proportion that has been observed to occur among another class similarly circumstanced.

The tables of mortality adopted in this country as the basis of calculation for insurance companies are three in number. That known by the name of the *Northampton Table* is the oldest now in use. It is founded upon observations made by the celebrated Dr Price, of the deaths registered for the population of one of the parishes of the town of Northampton, during the years between 1735 and 1780. This table, it is now acknowledged, shows far too high (or rapid) a rate of mortality, owing partly to no effect having been given to the fluctuations in the population of that parish, from immigration and other such causes, and partly to the great improvement which has taken place in the value of life since the middle of last century, consequent upon the introduction of vaccination and other improvements in medical science, as well as in the habits and modes of living of the people. In 1827 a select committee of

the House of Commons, appointed to investigate this subject, reported—'The evidence appears to your committee to be strong and decisive in favour of the use of tables which give an expectation of life higher than the Northampton. In truth, there is not even a *prima facie* case in their favour.'

The *Carlisle Table* was formed, not from the register of burials among a floating population, but from observations of the deaths which occurred, at each year of life, among a certain stated number of persons in the town of Carlisle. The observations were conducted by Dr Heysham, and the calculations made in the most scientific manner by Mr Joshua Milne, author of a valuable work on annuities.

Finally, the *Government Tables* were compiled from observations on the progressive mortality occurring among the government annuitants and other selected classes, distinguishing the sexes. They were prepared, under the directions of government, by Mr Finlaison, actuary to the National Debt; and in 1829 were adopted by parliament as the basis upon which their future calculations should proceed. Mr Finlaison's researches established the fact of the longer duration of female life. He also observed 'a very extraordinary prolongation of human life' in the course of the time over which his inquiries extended—so great, 'that the duration of existence now, as compared with what it was a century ago, is as 4 to 3 in round numbers.'

Besides these three, a table was framed by Mr Griffith Davies from the deaths reported from time to time among the members insured in the great Equitable Society of London, from its commencement in 1763 down to 1829, which has since been recalculated and continued down to a later period by Mr Morgan, the actuary to that society. This table is very valuable, as confirming the substantial accuracy of other observations, with which it very nearly corresponds. The relation which these tables bear to each other may be seen at a glance from the following table, showing the *mean expectation of life* at various ages according to each:—

At Age.	By Northampton.	By Carlisle.	By Government.			By the experience of the London Equitable.
			Males.	Females.	Mean.	
20	33.43	41.46	38.39	43.99	41.19	41.67
25	30.85	37.86	35.90	40.81	38.36	38.13
30	28.27	34.24	33.17	37.57	35.37	34.33
35	25.68	31.00	30.17	34.31	32.24	30.93
40	23.08	27.61	27.02	31.13	29.07	27.40
45	20.52	24.46	23.75	27.91	25.78	23.87
50	17.99	21.11	20.30	24.35	22.33	20.36
55	15.58	17.53	17.15	20.79	18.97	16.99
60	13.21	14.84	14.39	17.32	15.66	13.91

Independently of the acknowledged deficiency of the data on which the first-mentioned table is founded, the mere fact of its differing so much from any other authentic observation is of itself conclusive against it; and by parity of reasoning, the close agreement of the others affords strong presumptive evidence in their favour, and imparts a high degree of certainty to calculations based upon them. The Carlisle Table occupies a mean place between the male and female observations of government, showing a somewhat shorter duration than the mean of these. It also coincides very nearly with the experience of the Equitable Society. Considering that it is thus supported by two other sets of observations, and that the whole three extend over a period during which life was not so good as it has since become, the general opinion in favour of the safety of the Carlisle Tables for life-assurance may be held as well-founded. This opinion receives corroboration from the experience of the Scottish Widows' Fund, which extends over the last thirty-four years. In 1834 the auditor of that society reported, as the result of a careful investigation, 'that the expected number of deaths by the Northampton Table, which is the table of the society, is to the actual number during the whole progress of the society as 100 to

57; and the proportion of the expected number by the Equitable experience is to the actual number as 100 to 87. We have understood that the experience of the Scottish Widows' Fund since 1834 is even more favourable to life. If, then, we were to take the whole thirty-four years' experience of this society as a criterion, we should come to the conclusion that the Equitable experience, the Carlisle Tables, and the Government mean, are considerably within the verge of safety, while the Northampton Tables are so far from the standard of modern life, as to be, particularly with regard to the younger class of lives, quite unfit for use.

We have now to advert to

THE RATE OF INTEREST,

meaning the rate at which the yearly premiums may be expected to be improved.

This subject is one which does not admit of the same certainty as the other, and on which, accordingly, there may be great differences of opinion. In 1823, Mr Finlaison writes—'I take it for granted that it will be considered safe enough to assume that money, in a long course of years, will so accumulate, through all fluctuations, as to equal a constant rate of 4 per cent.; because, in point of fact, money has hitherto accumulated at 4½ per cent., whether we reckon from 1803 or from 1783.' Other writers, again, and among them Mr De Morgan, looking chiefly to the high price of the 3 per cent. of late years, say that not more than 3½ per cent. should be counted on. Practically, the investments of assurance offices are made on terms much more favourable. It appears, from the published report of the Edinburgh Life-Assurance Company, dated December 1838, that for the three preceding years (1836, 1837, and 1838, when interest was unusually low), the average rate realised on their funds was £4, 16s. 6d. per cent.—about 1½ per cent. higher than the return from the 3 per cents. during the same time. And this, it is stated, was obtained without any part being laid out in the purchase of reversions—on which, it is known, a much higher rate can be got. The example of this office is quoted merely from the circumstance of their report happening to state the precise return at that period. Other Scottish offices are said to have obtained a higher rate. Most of them state that their funds are invested 'about,' 'at,' or 'above,' 5 per cent. Indeed it is not conceivable that the offices could make such large returns to proprietors and members, in the shape of dividends and bonuses, if they did not generally improve money at about the rate last mentioned. From all of these circumstances, it does not appear likely that calculations for life-assurance, in which the interest of money is assumed at an average of four per cent., will, while Britain remains in nearly its present condition, prove unsound.

EXAMPLE OF LIFE-ASSURANCE CALCULATION.

According to the Northampton Tables, out of every 11,650 persons born alive, there will be 46 living at the age of 90. From these tables being ascertained to be unfavourable to life, this must be understood as not strictly the case, but it may be adopted for the sake of illustration. The same tables make it appear that, of the 46, 12 will die in the course of the first year, 10 during the second, 8 during the third, 7 during the fourth, 5 during the fifth, 3 during the sixth, and the last remaining life will fail in the course of the seventh year. It is a favourite mode of exemplifying life-assurance calculation, to suppose these 46 persons, aged 90, associating for the purpose of assuring £100 to each at death. They are supposed to proceed upon the principle of paying all that is required in one sum at first, thus forming a fund which is to answer all the demands which are to be made upon it. In this calculation the improvement of money has been assumed at 3 per cent. The object is to ascertain what sum, by way of present payment, each is to contribute to the fund, so that it may discharge £1200 the first year, £1000 the second, £800 the third, and so on. In order to discharge

£	s	d.
1200, at the end of the first year, the society must be provided with	1200, discounted at 3 per cent., for one year,	1165 1 0
1000, at the end of 2d year,	1000, ditto, for 2 years,	948 12 0
800, at the end of 3d year,	800, ditto, for 3 years,	732 3 0
700, at the end of 4th year,	700, ditto, for 4 years,	621 18 7
500, at the end of 5th year,	500, ditto, for 5 years,	451 8 0
300, at the end of 6th year,	300, ditto, for 6 years,	251 5 0
And in order to discharge the remaining L.100 at the end of the seventh year, with L.100, discounted at 3 per cent., for seven years,		81 6 3
In all,		£4225 10 9

This, divided by 46, gives £91, 17s. 2d. as the sum (technically called *premium*) which each person would need to pay in at the foundation of the society. And this sum of £91, 17s. 2d. is the present value of a reversion of £100, at the age of 90, according to the Northampton Tables, and taking interest at 3 per cent.

Supposing such a society to be constituted, and £4225, 10s. 9d. to be paid in by the 46 members, we shall see how its business would proceed until, at the close of seven years, death put a period to the account:—

The original contribution of L.4225, 10s. 9d. being put out to interest, at the end of the first year amounts to,	£4353 5 3
From which deduct for the twelve lives which fall in the course of the year,	1200 0 0
Fund remaining at the commencement of the second year,	3152 5 3
Which, bearing one year's interest, will amount to,	£3245 16 8
From which deduct for the ten lives which fall in the course of the year,	1000 0 0
Fund remaining at the commencement of the third year,	2245 16 8
Which, bearing one year's interest, will amount to,	£2314 8 2
From which deduct for claims,	800 0 0
Fund remaining at the commencement of the fourth year,	1514 8 2
Which, bearing one year's interest, will amount to,	£1559 16 8
From which deduct for claims,	700 0 0
Fund remaining at the commencement of the fifth year,	859 16 8
Which, bearing one year's interest, will amount to,	£885 10 3
From which deduct for claims,	800 0 0
Fund remaining at the commencement of the sixth year,	85 10 3
Which, bearing one year's interest, will amount to,	£897 1 8
From which deduct for claims,	800 0 0
Fund remaining at the commencement of the seventh year,	97 1 8
Which, bearing interest, will amount to,	£100 0 0
Which will exactly discharge the last remaining claim,	100 0 0

Practically, life-assurance is not effected upon lives so advanced as 90 years. It is common to confine business to ages under 60; and the great bulk of insurers are between 27 and 40, the time about which men in this country begin to feel the responsibilities of a family. But the calculations followed for the various ages are formed exactly in the above mode. All the persons of a particular age in a life-assurance society are considered as a distinct group insuring each other. Of those, for instance, at 30 years of age, it is calculated what proportion will die the first year, what the second, and so on; and from each the society looks for such a contribution, present or prospective, as may make up an aggregate sufficient, with the accumulation from compound interest, to pay the sum assured upon each life in that group. It is quite the same thing to the society, or, we shall say, to the general interest, whether the individual insurers pay the whole required contribution at once, or in a series of annual payments, which, as the plan convenient for the majority of people, is that generally adopted.

FORMATION OF RATES.

According to the principles of which we have given a slight outline, offices form scales of rates at which

LIFE-ASSURANCE.

they profess to do business. In these rates very considerable discrepancy exists, for many continue to calculate mortality according to the Northampton Tables, which, as already shown, give the decrement of life too high; while others proceed upon those more recently formed, which are certainly much nearer the truth; and some, again, assume interest at only three or three and a-half per cent., while others deem four not too high. There is also an allowance for the expenses of business to be added to the naked sums required by a regard to mortality and interest, and here also the minds of parties may differ, some allowing more and some less on this account.

In most cases the charges for life-assurance are considerably within the verge of safety. Hence companies generally divide good profits, and societies realise large surpluses, which fall to be divided among the insurers, in the form of additions to the sums stated in their

policies. The scales of the various offices may be classed in three grades or sets, of each of which we shall give a few examples, endeavouring, at the same time, to show how each particular grade of charges operates in the realisation of profits and surpluses.

Scales of the first or lowest grade are followed as yet by comparatively few offices; but the number is increasing. We presume that they proceed upon modern tables of mortality, and the expectation of 4 per cent. at an average, as, with regard to one of the following (the Scottish Provident), we have been informed that it follows the government table of males, and calculates upon money being improvable at the above-mentioned rate, adding from 10 to 15 per cent., according to age, for expenses of management, and as a guarantee against any unfavourable fluctuations of mortality and interest. We here, as elsewhere, limit ourselves to offices of undoubted probity:—

	20	25	30	35	40	45	50	55	Total Premiums between 20 and 60.
Aberdeen Assurance Company, - - -	L.1 14 7	L.1 18 1	L.2 2 0	L.2 7 3	L.2 16 5	L.3 4 6	L.3 19 8	L.4 19 0	L.129 7 9
Standard L. Assurance Company, Edin., - -	1 19 10	1 17 6	2 2 11	2 9 1	2 17 2	3 6 5	3 19 8	5 0 0	
Scottish Provident Institution (mutual),	1 15 8	1 18 0	2 1 6	2 6 10	2 14 9	3 5 9	4 1 7	5 1 11	121 8 8

The high premiums borne by the stocks of the two above companies, form a tolerably fair evidence (notwithstanding their having also higher scales) that business can be profitably transacted at these rates. It may likewise be mentioned that the Edinburgh Life-Assurance Company, which presents a scale nearly the same in aggregate amount as the above (£133, 4s.),

divides 6 per cent. upon its stock, the £10 shares of which stand at £14, 10s. in the market. The Scottish Provident was established in 1837; it has done a large amount of business, and its experience as yet tends to show that the rates are considerably within the verge of safety. The following is a selection of respectable offices in which somewhat higher rates are charged:—

	20	25	30	35	40	45	50	55	Total Premiums between 20 and 60.
Economic Company, London, - - -	L.1 14 7	L.1 19 0	L.2 4 3	L.2 10 11	L.2 19 9	L.3 11 9	L.4 8 0	L.5 10 3	L.141 13 6
Norwich Union Society, - - -	1 19 6	2 2 2	2 2 10	2 14 10	2 2 0	2 11 0	4 6 0	5 2 3	149 10 4
Guardian (mixed), - - -	2 1 0	2 5 4	2 10 7	2 17 0	3 5 0	3 14 11	4 8 0	5 4 8	146 3 3
Scot. Widows' Fund; Scot. Equit. Societies,	2 1 6	2 5 10	2 11 1	2 17 6	3 5 6	3 15 6	4 8 4	5 4 2	146 12 5

The Economic is a proprietary office, giving three-fourths of the surpluses or profits to the assured. It was established in 1823. In 1834 a bonus, amounting to 16 per cent. on the premiums paid, was declared; and in 1839 there was a second bonus, amounting to 31 per cent. on the premiums paid during the preceding five years. The Norwich Union, in 1816, gave a bonus of 20 per cent. on the amount of premiums deposited by the members insured previous to June 1815; a second bonus of 24 per cent. in 1825; and a third of 25 per cent. in 1830. The Guardian is a proprietary office, in which a proportion of profits not stated is given to the assured. Established in 1821, its first division of profits was made in 1828, and a second in 1835. At each period, the bonuses averaged rather more than 28 per cent. on the amount of the premiums paid thereon during the preceding seven years. The Scottish Widows' Fund and Scottish Equitable have both declared large surpluses. At the division of the first of these highly prosperous societies in 1825, the policies opened between 1815

(the commencement of the society) and 1820, were declared entitled to 2 per cent. for each year of their currency. In 1832 the same policies received a further addition of 3½ per cent.; and at the same time those opened between 1820 and that time, were declared entitled to additions amounting to 1½ per cent. per annum. In 1839 a retrospective bonus of 2 per cent. per annum was declared on all policies. The effect of these additions is, that policies for £1000, opened before 1820, at whatever age, amounted in 1845 to £1809, 8s. 7d. In 1841 the Scottish Equitable made its first division of surpluses, amounting to 2 per cent. per annum on all policies of above five years' standing; so that the heirs of a person who insured £1000 in 1831 (the first year of the society), would, in the event of his decease in 1850, realise £1429; and so on in proportion.

A third class of offices, adopting, like the preceding, the Northampton Tables, and generally of old standing, and acting upon old calculations, present higher scales of rates, of which we shall give a few examples:—

	20	25	30	35	40	45	50	55	Total Premiums between 20 and 60.
Globe Company, - - -	L.2 3 7	L.2 8 1	L.2 13 5	L.2 19 10	L.3 7 11	L.3 17 11	L.4 10 8	L.5 6 4	L.151 5 2
Sun Company (mixed), - - -	1 16 11	2 2 6	2 9 2	2 16 8	2 6 4	2 17 2	4 14 2	5 19 11	154 16 6
Amicable Society (London), - - -	2 0 6	2 5 6	2 10 6	2 17 0	2 5 0	2 12 6	4 10 6	5 18 0	155 8 0

There are a few offices which charge still higher rates. The aggregate premiums of the London Assurance and National (mixed offices), are respectively £157, 0s. 8d., and £158, 3s. The London Life (mutual) is the highest, the aggregate of the scale being £171, 18s.

It is clear that, if business can be transacted by a company at a profit on a scale of rates amounting in the aggregate to £129, 7s. 9d. (as in the case of the Aberdeen Company), the last set of rates ought to give companies very large profits, and societies equally considerable additions to policies. The scale of the Globe is also that of the Rock and Atlas, proprietary offices granting a share of profits to the assured. In the Rock, where three-fourths of the profits are divided, policies opened in 1806 for £1000, at whatever age, were in 1842 £2001, 11s. In the Atlas, which has not announced to the public the share of profits extended to the assured, policies for £1000, opened in 1816, ranged in 1837 from £1838 to £1789, according to age.

The high rates are defended on various grounds. A company making high charges, and consequently good profits, may be supposed to have more stability than one making moderate charges; while, of a society pursuing business on the same plan, it may be said that the overplus becomes a kind of bank deposit, to be ultimately realised by the depositor. With regard to companies, the defence may or may not be sound, according as business is managed discreetly or otherwise—and there certainly are offices of that nature, entitled to the most implicit confidence, although they present moderate scales. The defence is of greater force with regard to societies; but even there it is not free from

objections. The high-rate societies, proceeding upon the Northampton Tables, commit a constant injustice to young and middle-aged members in favour of the old. The needless amplitude of their funds tends to occasion a less careful use of them in conducting the concern: there is, for instance, a greater temptation to give large commission to persons, who, as it is said, bring business; a practice in no respect different in morality from that of butchers and grocers who bribe cooks and butlers to favour them with their masters' custom. But the greatest objection to a needlessly high scale is, that it must act as an obstruction to the first step in what is generally one of the most important moral acts of a lifetime—the effecting of a life-assurance. We would here be understood to draw a broad distinction between an unsound low rate and one which is sufficient to satisfy a reasonable anxiety for security. Rates much below the first of the above three scales would be decidedly unsafe, taking all likely contingencies into account. On the other hand, it ought certainly to be possible to transact perfectly safe business upon a medium of that scale. Those who, for further caution, prefer the next scale, must be said to pay highly for it, if they resort to a company which gives no share of profits to the assured: if they become members of a society, large periodic additions to policies will be no more than their due.

In order to convey still more distinct notions respecting rates of life-assurance, we subjoin a scale of those which are required, exclusive of expense for management, upon the Carlisle Tables, taking money variously at 4 and 3½ per cent. :—

	25	30	35	40	45	50	55
4 per cent.,	L.1 10 4	L.1 15 1	L.2 0 5	L.2 7 6	L.2 15 6	L.3 7 3	L.4 5 8
3½ per cent.,	1 12 1	1 16 11	2 2 5	2 9 7	2 17 10	3 9 9	4 8 2

The rates actually charged by the offices which we have cited, may easily be compared with these. It will be found that the additions made for management and the security of the concern, even to the 3½ per cent. rate, are very considerable. The aggregate of the above ages at 3½ per cent. is £18, 16s. 9d.; that of the same ages by the actual rate of the Aberdeen Company is £21, 4s. 11d., or nearly 12½ per cent. higher; that of the same ages by the Scottish Widows' Fund is £24, 7s. 11d., or 29½ per cent. higher; while that of the London Amicable is £25, 11s., or above 35½ per cent. higher.

MORAL DUTY OF LIFE-ASSURANCE.

On this subject we add some remarks from a paper in 'Chambers's Edinburgh Journal,' No. 373, First Series. They are conveyed in language which is apt to appear unmeasured to one who has not given the subject much consideration—but, we believe, *only to him.*

'Such being the equitable and beneficial principles on which mutual-assurance societies are established, it is clear that they present, to men in the enjoyment of income, but possessing little property, a most suitable and favourable means of providing, in a greater or less measure, for the endeared and helpless relatives who may survive them. That only about 80,000 persons in the United Kingdom [written in 1839] should have taken advantage of life-assurance, being but 1 in 62 of the supposed number of heads of families, surely affords a striking view of—shall we call it the improvidence of mankind, or shall we not rather designate it as their culpable selfishness? For what is the predicament of that man who, for the gratification of his affections, surrounds himself with a wife and children, and peaceably lives in the enjoyment of these valued blessings, with the knowledge that, ere three moments at any time shall have passed, the cessation of his existence may throw wife and children together into a state of destitution! When the case is fully reflected upon, it must certainly appear as one of gross selfishness, notwithstanding that the world has not been accustomed to regard it in that light. It is unquestionably the duty of every man to pro-

vide, while he yet lives, for his own: we would say that it is not more his duty to provide for their daily bread during his life, than it is to provide, as far as he can, against their being left penniless in the event of his death. Indeed between these two duties there is no essential distinction, for life-assurance makes the one as much a matter of current expenditure as the other. One part of his income can be devoted by a head of a family to the necessities of the present; another may be stored up, by means of life-assurance, to provide against the future. And thus he may be said to do the whole of his duty towards his family, instead of, as is generally the case, only doing the half of it.

It may be felt by many that, admitting this duty in full, income is nevertheless insufficient to enable them to spare even the small sum necessary as an annual premium for life-assurance. The necessities of the present are in their case so great, that they do not see how they can afford it. We believe there can be no obstacle which is apt to appear more real than this, where an income is at all limited; and yet it is easy to show that no obstacle could be more ideal. It will readily be acknowledged by everybody who has an income at all, that there must be some who have smaller incomes. Say, for instance, that any man has £400 per annum: he cannot doubt that there are some who have only £350. Now, if these persons live on £350, why may not he do so too, sparing the odd £50 as a deposit for life-assurance? In like manner, he who has £200 may live as men do who have only £175, and devote the remaining £25 to have a sum assured upon his life: and so on. It may require an effort to accomplish this; but is not the object worthy of an effort? And can any man be held as honest, or any way good, who will not make such an effort, rather than be always liable to the risk of leaving in beggary the beings whom he most cherishes on earth, and for whose support he alone is responsible!

For a further account of modes of life-assurance, the reader is referred to the following number on THE SOCIAL ECONOMICS OF THE INDUSTRIOUS ORDERS.

## SOCIAL ECONOMICS OF THE INDUSTRIOUS ORDERS.

It is surely a deplorable feature in the condition of a large portion of the working-classes in this country, that they have little or no provision made against the necessities which arise to themselves or their families in the event of sickness, a failure of employment, or death. With some this is not the case, but it is the case with many; and the result is, that these persons have never more than a thin partition separating them from the realms of want and dependence. The effect which this is calculated to have need not be largely insisted on, for want and dependence are universally allowed to be productive of many evils. What is there to be expected from the moral nature of one who is every now and then obliged, perhaps, to ask for gratuitous medicine and medical attendance—to take bread from a parish officer or the managers of a charitable subscription—to trust to the pity of neighbours whenever anything like an exigency arises in his family—in short, is, for the supply of a great part of his needs, a stipendiary upon his fellow-creatures? These things are evidently irreconcilable with true manly dignity, with political independence, and with an upright bearing in any of the relations of life. The destitution of such individuals is commiserated when it arises—every humane person, who is himself above want, feels bound to contribute to its relief: the claim from suffering man to him who suffers in the smallest degree less, is irresistible. But while it is allowed that the need, when it does exist, must and ought to be relieved, all must likewise see that, in the effort to diminish one immediate and clamant evil, another of a serious nature is introduced. The working-man is morally deteriorated by ceasing to be self-dependent. Better, clearly, that this portion of the community were to place themselves, by efforts of their own, above all need for such degrading aid.

But then the working-classes realize such small gains, that they can spare nothing for this purpose. This may be said; but it is at the best only partially true. A great portion of the working-classes do most unquestionably, in ordinary times, realize enough to enable them to spare a little by way of provision for the future. Since many, most creditably to themselves, make such a provision, it may fairly be presumed that others, having the same wages, could do so also if they were willing. We may still more confidently presume that when some with comparatively small wages are able to save, those who are better off could save also. Now it often happens that the labourers of least skill, and who are least liberally remunerated, contribute as largely to savings' banks as their better-paid brethren. Where this is the case, and the circumstances of the men are otherwise equal, we cannot doubt that the latter class make a less economical disposal of their income. Clearly, they have only to imitate the frugal conduct of the small-wage class, in order to have ample means for making the provisions in question. On this subject, from various causes, many erroneous notions prevail. When practical men are consulted, we hear of an afflicting number of instances in which the higher-waged workmen are considered as securing little if any more comfort to their families than the other class, and perhaps not so much. We have heard masters of works declare that their men at 25s. a week did not, as a class, maintain their households, or educate their children, so well as those who had little more than half the sum. In a return from the Savings' Bank of Dundee, it appeared that, while there was £1189 deposited by 108 male weavers, a class whose wages average 8s. weekly, and £425 by 36 hecklers, a class whose average wages are 12s., there was only £637 from 56 mechanics,

men whose wages range from 18s. to 30s. Such facts—and we believe many of the like nature might be readily adduced—seem to prove that the working-classes have much more in their power for the promotion of their physical and moral wellbeing than is generally supposed. Admitting fully that many are ground to the dust by poverty, we cannot doubt that a far larger proportion have all but the will to take the proper means for preserving their social independence.

We do not profess here to inquire into the primary causes of the unendowed condition of the working-classes; but we can readily see various immediate ones—as intemperance, and bad management of resources. The tavern bill of the whole operative class in the United Kingdom must be an enormous one. Of above thirty-one millions of gallons of spirits prepared in one recent year, and for which twenty millions of pounds sterling would be received, we cannot assume less than two-thirds to have been consumed by the working-classes. These classes probably expend in this way three times the whole cost of the religious establishment of the country. In Glasgow, there was lately a tavern or spirit-shop for every 14 families; and it was calculated that not fewer than 30,000 of the inhabitants go to bed drunk every Saturday night. In the parish of St David's in Dundee, while there were but 11 bakers' shops, there were 108 for the sale of liquors. In the parish of Lochwinnoch in Renfrewshire, three or four times more money is said to be spent in this way than is required for the support of religion and education. The value of ardent spirits consumed in the parish of Stevenston in Ayrshire, with a population of 3681, exceeded the landed rental by £3836. These are startling facts, telling, if they tell anything, that a large portion of the earnings of the working-classes is worse than thrown away. Now, though it is well, certainly, to compassionate and relieve the sufferings of all who need, we cannot but be equally sensible that it is proper to tell the plain truth, and say that for much of this suffering our countrymen have themselves to blame. There has been of late years a hollow kind of cajolery practised towards them, discreditable to all parties, and of a dangerous tendency. We dismiss this entirely, and conceive it to be both paying them a greater compliment and doing them a greater service, to tell them that the conduct of a large portion of their class is in many respects reprehensible, and to show them how it might be shaped somewhat better.

We propose, therefore, in the present sheet to treat of various arrangements or institutions which have been devised for the benefit of the industrious orders, with a view to their maintaining their independence, or avoiding some of the greater evils which beset them. One of the most conspicuously valuable is

### THE SAVINGS' BANK.

Previous to the commencement of the present century, such of the humbler classes as were given to saving had no proper place of deposit for their spare funds, which they were obliged, therefore, to keep in an unfructifying hoard in their own possession, exposed to the risk of loss, or had to consign to some neighbour, who, though deemed safe, might turn out to be much the reverse. At the same time, in the want of a proper place for the deposit of spare money, those who might save, but did not, lacked one important requisite to their doing so. About the beginning of this century, it occurred to some benevolent minds that an important benefit would be conferred on these classes if there were institutions of the character of banks, but on a modest scale, in which the poor could deposit the smallest

sums they could from time to time spare, certain of being able to draw them forth when they pleased, with accumulated interest. Savings' banks—so named from their main object—were accordingly established almost simultaneously in Britain, the United States, France, and other countries. They were generally conducted by associations of benevolent persons, who gave the security of their own credit for the accumulated sums, and held forth every temptation in the way of liberal interest, courtesy, and promptitude in management, to induce the working-classes to resort to them.

For some years, this joint-stock but still private security was found to be sufficient for the purpose; but when it was understood that millions had found their way into savings' banks, it became apparent that something else was necessary in order to maintain the confidence which had at first been felt. The government was therefore induced to frame a variety of statutes (See article BANKS, No. 82) for the better regulation of savings' banks, and one in particular by which its own security was given for the safe keeping of the deposits. This was done under the guidance of the best intentions towards the industrious classes, who generally are depositors in savings' banks, and with as little interference as possible with private and local management.\* A substantial benefit was at the same time conferred, by the fixing of a rate of interest somewhat above the average of what could be expected in a country under the particular circumstances of the United Kingdom with regard to capital.

By the above-mentioned acts (9 Geo. IV. chap. 92; 3 Will. IV. chap. 14; 5 and 6 Will. IV. chap. 57; and 7 and 8 Vict. chap. 83), it is directed that all the funds deposited in National Security Savings' Banks must be paid into the Bank of England on account of government, and that the money so invested shall bear interest at the rate of £3, 5s. per cent. per annum, *whatever may be the fluctuations in the value of the public funds during the term of investment.* Depositors are thus afforded the best of all securities—namely, that of the *whole British nation*; while the National Savings' Banks are enabled, after paying all charges upon their establishments, to give a considerably higher rate of interest than the ordinary banks, or even the greater part of private savings' banks, allow on deposits. The highest interest which the law allows the National Security Savings' Banks to pay to depositors is £3, 0s. 10d. per cent. per annum; the difference between this and the rate allowed on the money invested by them in government securities being reserved as a fund for the payment of the officials of the banks and other necessary expenses. The rate of interest which is at present paid by these banks is £2, 17s. 9½d.; and whatever remains, after defraying all charges, is allowed to accumulate as a surplus fund.

Deposits of from *one shilling to thirty pounds* may be received by these banks, but no individual depositor is allowed to lodge more than £30 in any one year, ending on the 20th November, nor more than £150 on the whole: when the sum amounts to £200, no interest is payable. Charitable and provident institutions may lodge funds to the amount of £100 in a single year, or £300 in all, principal and interest included; and friendly societies, whose rules have been duly certified by the acts of parliament relating thereto, are permitted to deposit the whole of their funds, whatever may be their amount. Compound interest is given on the sums lodged, the interest being added to the principal at the end of each year in some banks, and the end of each half-year in others, and interest afterwards allowed on the whole. Any depositor may receive, on

\* Various rules are appointed by the legislature for the formation and management of savings' banks. An association of persons desirous of forming one in any place are enjoined first to frame a set of regulations for the management, and to submit these to the approval of a barrister appointed by government, without whose certificate they cannot enjoy a legal status, or any of the advantages which the legislature has thought proper to hold out for the encouragement of such institutions.

demand, the money lodged by him, if it do not amount to a considerable sum; and even in that case it will be returned on a few days' notice.

The wisest and most effectual provisions are made for insuring the proper management of the affairs of these banks. Each must have a certain number of trustees and managers, whose services are performed gratuitously; then a treasurer, actuary, cashier, clerks, &c.—all of whom must give security, by bond, to such amount as the directors of the establishment may judge sufficient. No portion of the funds invested in government security can be withdrawn, except on the authority of an order signed by several of the trustees and managers. Detailed reports of the transactions of each bank must be periodically forwarded to the Commissioners for the Reduction of the National Debt, and also exhibited to the depositors at the bank office. Of course government can only be responsible for the amount actually deposited in the Bank of England; but the respectability of the local managers is sufficient guarantee for the safety of the funds in their passage between the depositor and the national exchequer. To remove from the public mind all doubt as to security, and to render the system of savings' banks still more efficient, we understand that it is the intention of the legislature shortly to sanction a new set of regulations, chiefly affecting the local management and direction.

Under both the old and new systems, savings' banks have been highly successful in their object, and the money deposited in them reaches an amount which no one who regarded the habits of the working-classes thirty-five years ago could have anticipated. In 1840, the total sum was nearly £22,000,000; in 1844, upwards of £29,000,000; and at present, upwards of £32,000,000. In 1845, the number of depositors in England was 846,445; in Wales, 18,231; in Scotland, 81,170; and in Ireland, 95,348—making in all, 1,041,194. The amount of investments for the same year was £24,238,748 for England; £531,902 for Wales; £1,185,545 for Scotland; and £2,858,260 for Ireland—making in all about twenty-nine millions. But this sum, large as it is, does not embrace the whole amount of business transacted by savings' banks. During the same year there were in England belonging to charitable societies, 10,171 deposits, amounting to £589,627; and to friendly societies, 8773 deposits, amounting to £1,151,891; in Scotland, 635 charitable society deposits, yielding £35,891, and 398 belonging to friendly societies, yielding £57,493; in Wales, 220 deposits belonging to charitable societies, yielding £13,582, and 465 to friendly societies, amounting to £72,608; in Ireland, 669 deposits belonging to charitable societies, worth £41,798, and 405 to friendly societies, equal £21,528. In other words, the amount deposited by individuals and charitable and friendly societies in National Security Savings' Banks at the end of the year ending 20th November 1845, was £32,661,924—a vast amount certainly to be made up of such small and heterogeneous savings. The following table exhibits at a glance the elements of the investment:—

Depositors.	Number of Depositors.	Amount of Investments.
Not exceeding £20,	597,631	£3,851,027
... .. 50,	287,609	8,247,304
... .. 100,	115,737	7,815,347
... .. 150,	37,924	4,568,790
... .. 200,	21,302	3,683,971
Exceeding..... 200,	3,001	702,980
Individual Depositors,	1,041,194	28,614,455
Charitable Societies,	11,695	630,898
Friendly Societies,	10,041	1,903,515
Number of Accounts,	1,062,930	30,748,868
Friendly Societies in direct account with Commissioners for reduction of National Debt,	400	1,913,956
Gross Total,	1,063,418	32,661,924

SOCIAL ECONOMICS OF THE INDUSTRIOUS ORI

The kind of persons who deposit—that is, their status as to employment, amount of wages, locality, age, sex, and so forth—is an important point; and here, we fear, some disappointment must be felt. We have already seen that the average amount of deposits at Dundee is little larger amongst workmen of high than amongst workmen of low wages. In that town, out of 464 male weavers in the parish of St David's, with wages averaging 8s., 108 were depositors, or 1 in 4 $\frac{1}{2}$ ; of 181 flax-dressers, with wages averaging 12s., 36 were depositors, or 1 in 5; of 200 mechanics with 20s. of average wages, 56 were depositors, or 1 in 3 $\frac{1}{2}$ . The very small degree in which we thus see comparatively good wages favouring the saving principle, is surprising and lamentable. Another fact of a general character is not less striking. In many places, of the depositors in savings' banks, a majority are females. Female servants, in almost all places, form a conspicuous section. In the Dundee Savings' Bank, there were, some years ago, 237 accounts in the names of female servants (aggregate deposits, £2235), while (and this is equally remarkable) out of the numerous class of factory female workers, only one had an account. It has also been stated, that 'a few years ago, in Perth, it was found, from its savings' bank, that the women of the "Fair City" were laying up for the men, not the men for the women; that the young mechanics had forgot there were such things as want, or sickness, or age.' In the Edinburgh Savings' Bank, of the total number of accounts existing at November 1841, the majority were by females, and generally by females isolated in society, and depending on their own exertions, as appears from the statements given in the adjacent column, in which the amount of balances and the average amount of each person's balance are also shown. In the county of Fife, which is well balanced as to factories, mines, and agriculture, the chief depositors are found to be female servants, handloom weavers, and cottars—not the miners, mechanics, or factory workers, who have the highest wages.

In Glasgow the male depositors formed a majority; but here the factory operatives were comparatively a small section, numbering only 1282, while mechanics and artificers were 6774, notwithstanding the vast number of persons employed in factories in that city. The female domestics who deposited in the Glasgow Savings' Bank were 3862, and their aggregate accumulations, £22,378. With regard to this portion of the community, an interesting fact is mentioned in the report of the Edinburgh Savings' Bank for 1841. The five hundred accounts last opened by female servants in that bank, presented the aggregate sum of £2313, 2s. 7d.; but the first five hundred opened by the same class, four or five years before, showed a total of no less than £111,921, 10s. 4d. We here see, in a striking manner, how a little fund once begun by a person in humble circumstances, tends to accumulate in the course of a few years.

FEMALES.		
Domestic servants,	}	
Single women without designation—generally persons keeping house for a father or other relative, and having no other occupation,		
Married women without designation—generally the wives of operatives,		
Minors,		
Dressmakers, milliners, sewers,		
Widows, designated simply as such,		
Shopkeepers, lodging-keepers, householders,		
Female operatives, mill-workers, washers,		
Governesses and female teachers,		
Miscellaneous designations,		
Balances not exceeding 2s. each,		
Accounts in the names of females,		1

MALES.		
Mechanics and operatives of all kinds,	}	
Porters, chairmen, gardeners, and town and country labourers,		
Teachers, students, clerks, shopmen,		
Domestic servants, including public coachmen, waiters, and grooms,		
Shopkeepers,		
Soldiers and sailors,		
Public servants—as post-office, police, excise, &c.,		
Minors,		1
Miscellaneous designations,		3
No designation,		2,5
Balances not exceeding 2s. each,		2,5
Accounts in the names of males,		8,11
Total in the names of females, as above,		10,85
Societies,		16
Total accounts in operation at 20th November 1841,		19,180

It may be of service to many pe- walks of life, who are not much a- neas, to see an example of a sav- the following is one presumed to named John Smith, whose signat- pears in the last column, as ackn- which he has withdrawn:—

CHAMBERS'S INFORMATION FOR THE PEOPLE.

It is of still greater importance that a person who thinks of depositing should have a distinct idea of the benefit he is to derive in the way of interest. The interest at present [1849] given in savings' banks is at the rate of £2, 17s. 9½d. per cent.; the difference between this and £3, 5s., which the Commissioners of the National Debt allow, being, as already mentioned, reserved to pay expenses, &c. This being the interest allowed, any one may readily reckon how his money is to fructify, by supposing an addition of *one-thirty-fourth* being made to it at the end of every year. For instance, if he deposits 15s., and lets it lie for a year, he is then entitled to 15s. 5d. It is right that he should be fully aware that, in respect of interest, he is better off than the people of the middle and upper ranks who deposit in common banks; for not only does he get a higher per-centage than is generally given by these banks, but he has the advantage of *compound interest*; that is to say, the interest due to him at the end of a year is silently, and without any trouble on his part, added to and considered as a part of the principal, on which interest is to be given in future. Thus a common bank account and a savings' bank account, for the same sum, if left unattended to for a few years, would in the end come to a very different amount. In order that no one may be at a loss to calculate the interest he is to receive on a savings'-bank deposit, we present the annexed table, which shows simple interest for a year on a variety of sums:—

INTEREST TABLE, AT £2, 17s. 9½d. PER CENT.

Principal.			Month of 30 Days.			Year.			Principal.			Month of 30 Days.			Year.

A prejudice exists in the minds of many working-people, and is perhaps affected by others, against savings' banks, on the ground that, when a man is known to save, he is the more liable to have his wages reduced by his master, or to want work when there is anything like a general failure of employment. Surely there can be little foundation in fact for this notion. It is a general wish amongst masters that their working-people should save, and many endeavour to bring this about by instituting savings' banks, and acting as managers. It is felt by every master, that a workman who has saved a little, is likely to be a much more steady and respectable person than one who has not. Indeed, as it has been justly observed, a receipt from a savings' bank is one of the best certificates of steadiness and sobriety which a working-man can show. Let it also be considered that, with a little capital in his possession, a workman stands in a much more independent position with regard to his master than he otherwise could do. We cannot doubt that in these considerations there is much more than a counterpoise to the visionary fear of having wages reduced, or employment withheld, in consequence of possessing a bank deposit.

It would be difficult to over-estimate the importance of a little private hoard to a working-man. It not only proves a succour in the evil day, but it tends to improve his whole moral nature. Wealth has been the subject of many bitter remarks to both the poet and the philosopher; but it is after all a greater friend to virtue than to vice. Often a very small amount of it, acquired by honest industry, will supply a modest pride that supports, if it is not in itself, moral efficacy. Doing well in this small way suggests and leads to doing well in other ways. The saver may prove the stay of a declining parent or other friend; he can do a better duty to his children; he can contribute to philanthropic objects which interest and bring out his finest feelings. It may even happen that, from less to more, and with no sacrifice of peace of mind, he is enabled by saving to rise into a higher grade in society. One of the best of the immediate effects of saving is, that once fairly begun, it proves a preservative from many extravagancies and vices. Temptations may present themselves; but the mind reverts to the fondly-regarded little hoard in the savings' bank, and they are easily resisted. Hence, it is generally observed that, once

## SOCIAL ECONOMICS OF THE INDUSTRIOUS ORDERS.

a practice of saving has been commenced, a great revolution takes place in the character. Irregularities and improper self-indulgences disappear, and steadiness, sobriety, and reflection take their place.

These views are, we feel assured, accordant with general experience; but it may nevertheless be well to quote one testimony from a practical quarter in support of them. The following passages are from an unpretending tract, published several years ago, respecting an auxiliary to the Govan Savings' Bank, in Kerr and Company's Nailery:—

'Three years ago, nearly all the men in this work were seemingly constitutionally and hopelessly afflicted with a *spark in the throat*, and spent a very large portion of their wages on ardent spirits to quench it. As might have been expected under the circumstances, both their persons and dwellings presented standing proofs of their ruinous habits; and their employer was frequently annoyed by their suspension of labour to gratify their vitiated taste, at times when the hurried execution of orders rendered him most dependent upon them. However, by the exercise of a little kindly feeling towards them, matters began to assume a more pleasing aspect. By being regarded and spoken to in their sober intervals as rational and accountable beings, and having exhibited to them the advantages they were likely to derive from connecting themselves with the Total Abstinence Society and the Savings' Bank, one after another was cured of the long-existing malady, and not only took up a new position among his fellow-workers, as at once an advocate and an evidence of temperance and economy, but was enabled to provide himself and family with household comforts to which they had previously been strangers. With the view of cherishing such newly-formed habits, their employer afforded them the weekly opportunity of husbanding their spare earnings, by forming among them and conducting a little agency of the National Security Savings' Bank. The following summary of its transactions will show both the success of his labours, and the encouragement which the proprietors and managers of other public works are likely to enjoy in making similar efforts:—The nailery consists [written in 1842] of three shops or hearths, each accommodating four workmen. Among the twelve persons employed in these shops, and two junior members of one of their families, there are nine open accounts; the number of deposits has been 351, and the amount deposited, including interest, £61, 15s. 10d. The number of repayments has been 31, and the amount repaid £36, 11s. 9d., so that the balance due at the 20th November 1841, upon the nine open accounts, is £25, 4s. 1d., or about £2, 16s.—a small average, certainly, in comparison with that of some other trades, but presenting a pleasing contrast to the situation in which matters stood at the commencement of the agency, when scarcely one of the workmen could, on a Wednesday or Thursday, muster a sixpence of his previous week's earnings. One observation must yet be made; they are now *not only more independent and comfortable, but stand much higher in the estimation of their employers.*'

### THE FRIENDLY SOCIETY.

Savings, instead of being stored up in a bank, to be there constantly at command, may be disposed of by a working-man in a well-constituted friendly society, as a means of insuring for himself certain contingent and fixed benefits. Friendly societies generally embrace several objects, as the securing of a weekly sum during sickness, and a pension after a certain age. They are based on the principle of mutual insurance (see LIFE-ASSURANCE, No. 83); that is to say, members make payments, either at once or in small periodical sums, and thus constitute a fund, out of which such as happen to fall sick or to survive a certain age, are supplied, the uncertainty attached to all individual concerns being lost in the certainty which attends calculations involving great numbers. In some respects, and for some cases, joining a friendly society may be better

than becoming a depositor in a savings' bank. Sickness may come before the savings are considerable; or, if considerable, they may be melted away by a long-continued sickness; but after the first weekly payment is made to a friendly society, the member is secure of succour, however long his illness may continue, besides perhaps other advantages. It is possible, on the other hand, that a difficulty may be experienced, in certain circumstances, in keeping up the weekly or other payments required to secure the benefits of friendly societies. Here, however, it may be said, there is no more than the usual uncertainty attached to all things. Assuredly, the arrangement of a rightly-constituted friendly society furnishes a very considerable degree of security against some of the uncertainties of life.

It is to be regretted, of this excellent class of institutions, that many of them are founded upon erroneous principles, or rather upon no principles at all; and it often happens, therefore, that those who trust to them are disappointed, the funds falling short before all claims are satisfied. This was at one time not to be wondered at, as no proper calculations for friendly societies existed; but such is no longer the case, for sound calculations are now attainable. Nevertheless, there is still a considerable number of obscure societies scattered throughout the country, proceeding altogether at random, and by which the industrious classes are induced to misspend large sums. We trust that what we have now to state will be of some service in promoting the establishment of sound societies, and putting an end to such as are of a different kind.

One great mistake in the formation of friendly societies is to assume that each member should pay an equal sum, whatever his age may be. This is unjust; for the younger members have a less chance of becoming burthensome to the funds than the middle-aged; and, indeed, there is a rising scale of probability of sickness throughout all the years of a man's life. The Highland Society found that, between twenty and thirty, men are liable at an average to be half a week indisposed per annum. Between thirty and forty, the average was about two-thirds of a week. At forty-six, it became a full week; at fifty-seven, two weeks; at seventy, eleven weeks. The society, from taking unsuitable grounds for their calculations, made out the probabilities of sickness too low. In the following table, three sets of calculations are given, as to the proportion of sick out of one hundred at particular intervals of age:—

Ages.	Highland Society.	English Benefit Societies.	Mr Edwards' Theoretical Table.
20 to 30	1-14	1-54	1-72
30 ... 40	1-32	1-83	2-30
40 ... 50	1-97	2-56	3-10
50 ... 60	3-60	4-32	4-51

The difference in the three columns is here of little consequence. They at least agree in representing *increase of years as attended by increased liability to sickness*. Now a rightly-constituted friendly society is bound to advert to this circumstance. To admit all ages at an equal payment, is clearly making the younger members pay for the elder, who should have entered at an earlier age, and been paying all along.

Another great error in the constitution of benefit societies is in making them for a year only. Many of the old friendly societies having ended in disappointment, in consequence of want of right calculations, or bad management, or speculation of the funds, the working-classes have contracted the notion that there is more safety in a yearly term. The immediate payments are also less than in a well-constituted friendly society. *Yearly societies*, as they are called, usually originate with some individual, often the keeper of a tavern, who advertises that a society will be formed in his house on a particular day. Applicants for admission pay one shilling as entry-money, which goes into the pocket of the originator of the scheme, by way of

rent. The objects are generally threefold—namely, a fund for sickness and funeral expenses, a deposit fund, and a loan bank. Towards the first, there is perhaps a weekly payment of twopence, or more if necessary, together with the interest arising from the loan of money to the members. Towards the deposit fund, there is a payment ranging generally from sixpence to two shillings, the accumulations being received back when the society closes. The money deposited is employed in making loans to such of the members as desire such accommodation, within the amount of their several entire deposits for the year, one penny per pound per month being charged by way of interest. The surplus, if any, of the twopences and interest, after sick and funeral money, books, and other necessities are paid, is divided amongst those members who may be clear of the books at the close of the society. Some such societies are formed by a spontaneous association of persons, who prefer renting a room for their meetings, and thus escape the temptations of a tavern; but none of them avoid the errors of an equality of payments for all ages, and the yearly dissolution. The youth of fifteen, who is not liable to half a week's sickness per annum, pays as much as the man of fifty-seven, who is liable to two weeks. Should sickness befall any one towards the close of the year, he is left, when the society dissolves, quite unprovided for, because he cannot enter another society in a state of sickness. Considered as a deposit for savings, the yearly society is strikingly inferior to the savings' bank, in as far as the depositor cannot take out money without paying an exorbitant rate of interest. Finally, these societies are generally under the care of obscure persons, who can give no security for the funds placed in their hands, and who in many instances become bankrupt or abscond before the final reckoning. Yearly societies are, indeed, in every point of view, a most objectionable class of institutions, to which working people would never resort but for their ignorance and unweariness, and the temptations held out to allure them.

A well-constituted friendly society involves, in the first place, the principle of payments appropriate to particular ages, as no other plan can be considered equitable. It stands forth before the working-classes as a permanent institution, like the life-assurance societies of the middle and upper classes, and necessarily requires its members to consider the connection they form with it as an enduring one, because its grand aim is expressly to make provision at one period of life for contingencies which may arise at another—youth, in short, to endow old age. By a yearly society, a man is left at last no better than he was at first, as far as that society is concerned; but the proper friendly society contemplates his enjoying a comfortable and independent old age, from the results of his own well-bestowed earnings.

It is also essential to the character of a proper benefit society, that individuals be not admitted indiscriminately. To take in a person in bad health or of broken constitution, is unjust to those members who are healthy, because he is obviously more likely to be a speedy burthen to the funds. Here, as in life-assurance societies, it is necessary to admit members only upon a showing that they are of sound constitution and in the enjoyment of good health. And it may be well to grant no benefits until after the member has been a year in the society. By these means men are induced to enter when they are hale and well, instead of postponing the step until they have a pressing need for assistance, when their endeavour to get into a benefit society becomes little else than a fraud.

Government has thought proper to interfere with its aid in the formation of friendly societies, though not compulsorily. An association of persons forming one, has the means of ascertaining the soundness of its principles, and also entitles itself to deposit funds in savings' banks, with the government security and at not less than £3, 0s. 10d. per cent. per annum, by submitting the proposed rules to the barrister appointed to certify them, to whom a fee of a guinea is payable. Under the

sanction of government, tables have been formed by a highly-competent person, John Finlaison, Esq. Actuary of the National Debt, for the guidance of friendly societies; and these are easily to be had,\* so that it is quite inexcusable to proceed upon random and unauthenticated data. Before quoting any of these tables, we shall endeavour to explain how they are formed.

We have an idea of a benefit society in its simplest form, if we suppose a hundred men, of exactly 33 years of age, to associate, and make such a payment at first as may be sure to afford each man that shall fall sick during the ensuing year one shilling a day during the term of his sickness. Taking (for the sake of illustration) the Scottish Tables, we find that, amongst such a body of men, there will be about 66 weeks of illness in the course of the year. This, multiplied by 7, gives the whole sum required, £23, 2s., or a little more than 4s. 6d. each, which, less by a small sum for interest, will accordingly be the entry-money of each man. A society of individuals of different ages, each paying the sum which would in like manner be found proper to his age, would be quite as sound in principle as one on the above simple scheme. It is only a step further to equalise each man's annual payments over the whole period during which he undertakes to be a paying member.

We shall suppose that the superannuation allowance or pension is contemplated as commencing at 60 years of age. It is necessary to consult tables of mortality, in order to ascertain how many may be expected to reach that age, and how long each of these has a chance of surviving it. Having already treated of tables of mortality (see the article on LIFE-ASSURANCE, No. 83), we shall not say much on this subject. The table presented by the Highland Society, as proper for friendly societies, is a mean of the Northampton, Carlisle, and Swedish Tables, and may be regarded as tolerably safe for both life-assurance and annuity schemes. It shows that, of 1005 persons of 21 years of age, no fewer than 528 reach the age of 60, 336 that of 70, and 127 that of 80; thus making it evident *how absurd it is for a working-man to think that he has an extremely small chance of growing old, so as to need a provision.*

Another point for consideration is the rate at which the funds of the society may be improved. In most cases, we believe, it is best for such societies to rest content with taking advantage of the privilege which they enjoy by act of parliament, of depositing their money in the funds or the savings' banks, in which case they are sure to obtain for it interest at a rate of not less than £3, 0s. 10d. per cent. per annum.

Proceeding upon these or nearly similar grounds of calculation, Mr Finlaison formed the table which is given at the top of the next page, to show in one sum (and also in an equivalent monthly contribution, to cease at the age of 65) the value of an allowance of four shillings per week during sickness, from and after each age until 65; combined with an allowance or pension of two shillings per week, commencing payment at the age of 65; and further combined with a payment of four pounds whenever the death of the purchaser should happen:—

We would here call particular attention to a point of view in which savings' banks and friendly societies might be regarded as favourable to each other. It will be observed that, for the sum of about thirteen pounds, at the age of thirty-four, a man can insure himself against absolute want under all future contingencies except deficient employment. Now, at that age, a prudent and careful man, who has begun early to frequent the savings' bank, may without difficulty have saved thirteen pounds. Let him draw his thirteen pounds from the savings' bank, and place it with the friendly society, and he is all but an independent man for life. This is a course highly worthy of the attention of

\* See 'Instructions for the Establishment of Friendly Societies.' Printed by W. Clowes and Sons, London, for her Majesty's Stationery Office. 1835.

domestic servants, who in the latter years of life are so often exposed to want.\*

The scheme of a right friendly society may be further illustrated by the actual arrangements of one of approved character, which happens to be well known to us. We allude to the Edinburgh School of Arts' Friendly Society, established about twenty years ago. This society, although originating with certain of the members of, and friends to the School of Arts (a species of mechanics' institution), and taking its name, is not otherwise connected with that institution, but is open to all persons, male and female, residing in Edinburgh. It has three separate funds or schemes—namely, a *Sickness Fund*, a *Deferred Annuity Fund*, and a *Life Assurance Fund*. One share of the sickness fund entitles the member during sickness to 10s. a week for 52 weeks, 7s. 6d. a week for other 52 weeks, and 5s. a week for all future period of sickness until the age of 60 or 65, according to the age of superannuation fixed at entry;

\* Friendly societies and savings' banks sometimes appear as rival institutions, and their respective merits have been keenly canvassed. Both have certainly their peculiar advantages. There is much in the consciousness of having a small fund stored up, and in the power of employing it for any particular purpose at pleasure; but it cannot be doubted that a reserve fund is a less efficient protection against contingencies, such as sickness, and death itself, than connection with a sound friendly society. The difference is like that between taking one's risk of loss from fire, and paying into an insurance office. Whenever there is a contingency, the cheapest way of providing against it is by uniting with others, so that each man may subject himself to a small deprivation, in order that no man may be subjected to a great loss. He upon whom the contingency does not fall, does not get his money back again, nor does he get it for any visible or tangible benefit; but he obtains security against ruin, and consequent peace of mind. He upon whom the contingency does fall, gets all that those whom fortune has exempted from it have lost in hard money, and is thus enabled to sustain an event which in all probability would otherwise overwhelm him.

The individual depositor, not the contributor to a common fund, is really the speculator. If no sickness attacks him during his years of strength and activity, and he dies before he is past labour, he has been successful in his speculation; but if he fall sick at an early period, or if he live to old age, he is a great loser; for his savings, with their accumulations, will support him but a short time in sickness; or even if he retain something in old age, after having provided for his occasional illness, the annuity which he can then purchase will be very inferior indeed to that which he would have obtained, if he had entitled himself to the benefit of the accumulated savings of all those who, having contributed for many years to a superannuation fund, had never reached an age to require it.—Report of Committee on Friendly Societies, 1823.

and thereafter his contribution to the enjoyment of the L share of which entitles the £8 a year, commencing at 61 at his entry. One share of is a sum of £10 payable at this case, as in the others, the age of 60 or 65.

The rates are calculated from sickness table, increased by 5 case may be considered as sound healthy men are admitted compounded of the Northamp assuming the rate of interest yearly; and the only charge 2s. 6d. entry-money to each payable by each member of each;

The life-assurance fund of from the other two, and may be its table being the only one which presents the advantages humbler classes, we extract it that females are admissible at Half-a-crown of entry-money in

## CHAMBERS'S INFORMATION FOR THE PEOPLE.

The sickness and annuity funds are essentially connected, and the tables for them are subjoined. It is to be remarked, that two, three, or four shares may be taken in all of these funds. Towards the annuity fund females pay one-fourth additional, in consideration of their lives being so much better than those of men.

So that a person of the age of 25, for an entry-money of 7s. 6d., and a payment of 2s. 2d. a month until the age of 65—or £1, 5s. 9d. a year—may secure an allowance of 10s. a week during sickness for 52 weeks; 7s. 6d. a week for other 52 weeks; and 5s. a week during the whole remaining period of sickness until the age of 65, an annuity of £8 a year during life after 65, and a sum of £10 at death.

For 4s. 4d. a month, or £2, 11s. 6d. a year, a person may obtain double of these allowances.

At an examination of the society's transactions and funds in December 1840, it was found that, after twelve years of business, when the deaths of unfree members, or persons who died in the first year of membership, were deducted, the mortality was within that allowed for the tables; and that all the three funds were in a good condition, each showing a surplus over what is necessary to make good the claims to which it was liable, when the value of the future contributions was taken into account against the value of the promised benefits.

For those who find occasion to go deeper into the subject of friendly societies, with a view to founding such institutions, we would recommend a careful perusal of the work which Mr Charles Ansell prepared for the Society for the Diffusion of Useful Knowledge, and which was published by that society in 1835. Much benefit might also be derived from Mr William Fraser's papers on Friendly Societies, published in Professor Jameson's 'Philosophical Journal' in 1827.

#### THE LOAN SOCIETY.

The modern history of Scotland has proved that advances of money to persons of the trading class, made by the banks under prudent cautions with respect to security, and the personal character of the borrowers, have a beneficial effect, supplying materials on which industry may work, and at once enabling many individuals to thrive, and giving a powerful impulse to the country at large. The well-cultivated face of our northern region bears powerful testimony to this fact. The institution called a Loan Society contemplates the same benefits to be conferred on a humbler portion of the trading class than those who resort to banks. By making small advances to such persons, it enables them to make little ventures in business which they could not otherwise have attempted, and often sends them forward upon a career which leads to their permanent advancement in life. The purchase of a cow or horse, of farm or mechanical implements, the discharge of rent, and the fitting out of a child for service or apprenticeship, are amongst the chief objects for which such loans are desired in the humbler walks of life. One might at first sight dread the effects of such anticipations of income; but, practically, the loan system, when rightly conducted, works well, and is productive of much good. 'A loan fund,' says a late writer, 'is a savings' bank reversed, and even leads to the savings' bank, if well managed. For instance, I have before me now the case of a man who, though he has a family, is able to put by at least one shilling weekly. I might have urged him for ever to do so, but it would have been to no purpose. He came to me to borrow 30s. from the loan fund to buy corn to fatten his pig; he paid back this regularly at the rate of one shilling a week; and at the end of thirty weeks I said to him, "Now, you have been owing me money, and have felt no inconvenience in paying it back; why should you not begin to make *me owe you*?" He had nothing to say to this, and is now a regular depositor in the Savings' Bank through my hands.'

Loan societies are not institutions of yesterday; but, until a recent period, there were none upon an equitable or philanthropic footing. Government, sensible of the erroneous principles on which they were generally conducted, obtained an act in 1835 for their better regulation. By this statute certain benefits were held

\* 'Prospects and Present Condition of the Labouring-Classes.' By a Beneficed Clergyman. T. and W. Boone, London.

## SOCIAL ECONOMICS OF THE INDUSTRIOUS ORDERS.

out to such loan societies as should be formed upon principles approved of by a residing barrister, and enrolled in conformity with the provision of the act for benefit societies. The principal benefits offered were exemption from stamp-duty, and certain powers for recovery of loans. Enrolled loan societies were forbidden by this act to make loans of above fifteen pounds, or to make in any instance a second loan until the first should be paid off. A scheme of rules for a loan society conformable to law is presented in the pamphlet quoted below.\*

It seems here necessary to state, in the most explicit terms, that loan societies formed by interested individuals, are entitled to no confidence, being almost universally usurious and oppressive in their modes of dealing, and a source of great misery to the poor. There are upwards of two hundred loan societies in London, and almost without exception they are of the same character as pawnbroking establishments.† On this subject we quote the following passages from a valuable communication which appeared in the 'Times' newspaper:— 'They generally originate with a knot of small tradesmen, who, having a surplus over the demands of their immediate business, find in them a profitable employment of their money. A capital of £500 has been known to start such a society—the paid-up capital eventually to be £2000, in shares of £5 each. It is very rare that the whole of the capital is at once paid down. Their rules in the outset describe the name and the constitution of the society; then follow the terms on which the shareholders have taken their shares, and the manner in which they are to receive a return for embarking money, which is the allowance of 4 per cent. interest per annum on the amount of subscription, while the balance of profit afterwards accruing is to be declared as a dividend. There are separate rules which apply to the borrowers from the society, which are called the "borrowers' rules." The general place of business is a public-house; some few, but very few, are carried on in offices hired for the purpose. The borrower has in the first instance to call on the secretary, director, or treasurer, all of whom are allowed to sell (at a profit) what are termed "application papers," and purchase one (they are either 2d. or 3d. each), fill in the amount of the loan he requires, and leave it with the name of one or two sureties, according to the amount, for the inspection of the directors. He calls again, and has to pay 1s. for his security being inquired into, which goes into the pocket of the director whose turn it happens to be to look after the securities, the emolument of this office always going in rotation. He calls again, and is told whether or not his security is sufficient; if not, he gives another security and another shilling; if it is, he is told to call on a certain evening when the loans are made, and he will be attended to. Should he give half-a-dozen securities, and none prove acceptable, he pays his six shillings—for nothing is returned. When the evening arrives, he is called in his turn before the secretary, treasurer, and two directors, who form the authorised court for the conduct of the business. He is asked what amount he wishes to borrow. Perhaps it is £5 for six months: the first thing is to deduct 5 per cent. from the amount of the loan, 1s. for the book with the "borrowers' rules," in which will be made the entries of his weekly payments (for the loan is repaid in this manner), and the first week's instalment, and then in addition 1d. in part payment of the rent of the office, and 1d. towards the secretary's salary, both of which expenses he is obliged by the "rules" to bear in common with the rest of the borrowers weekly. Should he fail to keep up his weekly instalments, he is written to by the secretary calling upon him to pay, and for this

letter he is charged 3d., a fee for the benefit of the secretary. If he does not pay due regard to this, he is, at the expiration of three weeks, summoned before the magistrates of the district, who, however, have shown a disinclination to enforce the payment of the extras, and have confined their decisions merely to the sum due to the society after the deduction of the legal interest. That such societies occasionally sustain losses there is no doubt; but these losses are trivial in comparison to the immense profits they make, as will be seen from the fact that one of them, upon a capital of £2000, was known to declare on the first half-year's business a dividend of 15 per cent., and on the second half year a dividend of 18 per cent.'

A proper loan society is a modest association of philanthropic persons, connected with some limited district, who wish to aid the meritorious poor of their neighbourhood with small advances of money, with or without the prospect of a small interest for their outlay. Anxious only for the welfare of their humble neighbours, they extend their aid on terms strictly equitable; while they guard against abuses of another kind, by making loans only where, from personal knowledge, they are assured that a good use will be made of the money. It is only in such circumstances that a loan society will do any good, as it is only under certain circumstances, as to prudence and careful management, that the Scotch system of banking, which loan societies resemble, is attended with the contemplated results.

As far as our information enables us to judge, the loan-fund system is nowhere on a better footing than in Ireland. Private, irresponsible, and usurious loan societies exist there, as elsewhere, but apparently in less proportion to those of a beneficial character. The extensive utility of loan funds in Ireland is owing to the establishment, by an act in 1836, of a central board of commissioners, with power to inspect the books of all societies formed under the act. In consequence of this statute, there are now from two to three hundred loan-fund societies throughout Ireland, conducted on philanthropic principles, and said to be producing a great amount of good. In these societies all profits, after paying clerk's salary and other unavoidable expenses, are applied to charitable purposes. It appears that in 1840, 215 such societies were circulating £1,164,046 amongst 463,750 borrowers, and that £15,477 of profit had been realised in three years.

Mr and Mrs S. C. Hall, in the agreeable work on Ireland published by them, give the following account of the way in which one of these societies is usually constituted, and the manner in which the business is subsequently conducted:— 'The resident gentry of some locality in which no loan society exists, perceive that such an institution is required, or would benefit the people in the district. A meeting is called, and as many as are inclined to become depositors state their intention of taking debentures from the new society, for which they receive interest, in some places 5, and in others 6 per cent. One party is voted treasurer, another honorary secretary, and three or four others trustees. Rules for the government of the society are then drawn up, and it is imperative that each set of rules shall contain a provision that no manager or trustee shall directly or indirectly derive any profit from it. Another rule must ascertain the limit to which the managers shall be at liberty to go in expenses of management; and a third, that the treasurer shall become bound with solvent sureties in a reasonable amount for the faithful performance of his duties. These rules are then transmitted to the secretary in Dublin Castle, for the approval of the Board, who make any alteration in them they may deem expedient; and the copy is then returned to the society, that three fair transcripts may be made and sent up for certification. On their reaching the secretary, he submits them to the certifying barrister, who, if they are in accordance with the acts, attaches his certification and signature that such is the case. One of these transcripts is then lodged in the office of the secretary to the Board, another with

\* 'Instructions for the Establishment of Loan Societies.' London: Printed by W. Clowes and Sons, for her Majesty's Stationery Office. 1837.

the clerk of the peace of the county in which the society is situated, and the third is transmitted to the treasurer of the society, as a voucher that his society is entitled to the privileges conferred by the act.

The society is then in legal existence, and commences operations. A person is appointed clerk, and to him the intending borrowers apply for application-papers, which are according to the form printed in the sub-joined note,\* and for each of which a penny or a half-penny is generally charged.

This being filled up, and returned by the applicant, his solvency and general character, with those of his sureties, are considered by one or two of the trustees in council met for the purpose; and if approved, the full loan applied for, or such portion of it as they may think proper to grant, is paid to the borrower, stopping, at the time the loan is issued, sixpence in the pound by way of interest. The borrower then receives a card, on which the amount lent to him is entered, and the instalments he pays are marked off. A duplicate of this, or a proper account of the transaction, is of course booked by the society. The borrower, and his sureties for him, bind themselves to repay the amount of the loan in twenty weeks, by instalments of one shilling in the pound per week. Thus, if a borrower applies for a loan of £5, which is approved, the society hands him £4, 17s. 6d., retaining two shillings and sixpence as interest. He then pays five shillings for twenty weeks, and the £5 is paid off. Should the borrower run into default, he subjects himself, in most societies, to a fine of one penny for the first week, and threepence for the second and every succeeding week, on each pound lent him; and should he remain two weeks in default, his sureties receive notice that they will be sued for the amount, together with the fines incurred; and unless the borrower comes in, this is immediately done. But in the very great majority of cases no such steps are necessary, the poor borrowers being generally very punctual in their repayments.

It has been objected by some, that the borrowers lose their time in repaying these instalments, but in practice the personal attendance of the borrower or his sureties is seldom given. The instalments of a whole neighbourhood are frequently brought in by a child, or some old person, fit for no other employment, who goes, *per vicem*, for two or three town-lands. "Indeed," remarks the Rev. Mr. Nixon, of Castle Town, "it is quite delightful to see the confidence reposed by the borrowers in the

persons who carry their instalments, and also the fidelity and accuracy, nay, even the tact, that these latter exhibit in the discharge of the duty they have undertaken." In some places the amount of interest charged is less than that above stated, and in others the fines are higher. There is no uniformity in these matters, nor have the central Board any power of enforcing it, though it is evidently desirable.

Mr Hall, advertising to the Third Report of the Loan Fund Board to Parliament, says, "It appears by this return—and the circumstance is so remarkable as to appear at first incredible—that out of an amount of £1,164,046 circulated in small loans amongst 463,750 individuals, so small an amount as £360, 18s. 8d. only should have been lost, or about  $\frac{1}{30}$  in the pound. We were very sceptical on this point, and consequently directed vigilant attention to the subject; when, what was our surprise to find that even this £360—this  $\frac{1}{30}$  in the pound—is considerably more than has been really lost, or left deficient by the poor borrowers! From the "list of societies whose accounts show a loss on the transactions of the year 1840, after paying interest to depositors and expenses of management," we took the first—namely, Mitchelstown, where the reported loss was £43, 2s. 6d., when we ascertained that this society lent during 1840, £5420 amongst 3070 borrowers, who paid £135, or sixpence in the pound, for its use, besides £11, 10s. 10d. for the price of their application-papers and cards. The society paid in interest for money lent to it, and expenses of management, £190, 3s. 4d., and the difference between its receipts and disbursements constitutes this £43, 2s. 6d., not one penny of which was lost from defaulters. We are informed by a person in every way competent to judge, it is his firm belief that out of this £1,164,046 lent, not the odd £46, or not *one-tenth* of a farthing in the pound, was unpaid. This fact alone speaks volumes for the honesty of the people, and their appreciation of the benefit which the loan funds confer on them.

It has been argued that this security from loss has arisen in consequence of the powers which the law gives for the recovery of the loans; but the observation is equally applicable to societies more strictly private. For example, in New Ross a society has been established upwards of forty years, for the lending small sums to the poor; and the sum lost during the whole of that period is within five pounds. This fact we give upon the authority of the Rev. George Carr; we could adduce others equally strong, and we have no doubt might receive similar statements from nearly every institution of the kind in Ireland. We rejoice greatly at the opportunity thus supplied us of bearing out, by unquestionable proofs, our own opinions in favour of the honesty of the Irish peasant. It is indeed a subject upon which satisfactory evidence is especially necessary; for it has been too frequently and too generally questioned in England, where, upon this topic particularly, much prejudice prevails, and where it has been far too long the custom to

"Judge the many by the rasal few."

We therefore, from the very minute inquiries we have instituted, have no hesitation in arriving at the conclusion, that the loan funds in Ireland will speedily become, nay, are already, mighty engines either for good or evil, according as they may be worked and superintended. Where properly managed, they cannot fail to exercise a vast influence on the moral and social condition of the people; where conducted carelessly, or by parties endeavouring to force business for their own gain, they may be indeed considered a moral pestilence, blighting the energies of the surrounding population, and fostering habits of improvidence or dishonesty.

THE ANNUITY.

The purchase of an annuity is a mode of providing for the latter part of life, which may be the most appropriate in some instances, especially where a person

## SOCIAL ECONOMICS OF THE INDUSTRIOUS ORDERS.

is unconnected with wife, children, or other near relatives, or where these have been otherwise provided for. When the case is different, such a mode of provision is liable to the charge of selfishness, in as far as it concentrates the benefit upon the purchaser alone; it has also been thought to tend to encourage improvident and careless habits, seeing that, once assured of a competent provision for life, the stimulus to further saving is in a great measure destroyed.

There are numerous companies which grant annuities on the principle of making a profit by them; and sometimes this branch of business is carried on in connection with that of life-assurance. There are also associations of individuals for obtaining annuities and endowments to widows and other nominees on the mutual assurance principle; and one large class of these, at present flourishing in various parts of the United Kingdom, are said to be based on unsound calculations, and fraught with disappointment to those relying upon them. There is indeed one circumstance generally unfavourable to annuity business—namely, that the ordinary tables of mortality present views of the expectation of life somewhat below what is at present the truth in England. Hence what makes life-assurance business everywhere so prosperous, is precisely that which tends to make annuity business a source of loss. It is obvious that, where individuals unite for annuities, and too low charges are made, those dying first will secure an over-proportion of the benefits, and leave those who come behind nothing but an empty purse.

With a view to encourage persons of the humbler classes to provide of themselves for their latter years, the government obtained an act (3 and 4 Will. IV. c. 14) to enable trustees of the legally-established savings' banks to sell annuities of not less than four or more than twenty pounds upon the security of the national credit. The same act provided that, in parishes where there was no savings' bank, a society for granting such annuities might be formed, provided that the rector or minister of the parish, or a resident justice of peace, should be one of the trustees. Any person above fifteen years of age was entitled to purchase such an annuity, which might be to commence immediately, or at a future period of life, or for a limited term of years, at the pleasure of the party, and might be paid either in one sum or in half-yearly sums, convertible into quarterly by dividing the annuity, and commencing the two parts at different periods of the year. The whole arrangements of this act were dictated by the most considerate benevolence towards the classes designed to be benefited. To quote an authoritative document:—'Provisions are made for enabling the party to make his annual payments, or receiving the annuity, at any other society than the one at which the contract was originally entered into. Upon the death of the person on whose life the annuity depended, a sum equal to one-fourth part of the said annuity (over and above all half-yearly arrears thereof respectively) will be payable to the person or persons entitled to such annuity, or his, her, or their executors or administrators (as the case may be), provided such last-mentioned payment shall be claimed within *two years* after such decease, but not otherwise; provided also that the fourth part of any expired life annuity, payable under the provisions of the said act, will not be payable, nor be paid upon, or in respect of any *deferred life annuity*, unless one half-yearly payment of such deferred life annuity shall have been actually paid or become due at the time of the decease of the nominee. Independently of the advantages which are thus afforded to the industrious classes to obtain, by small payments, a certain provision in old age, or at any other stated period, *secured by government*, and of which they cannot be deprived on account of miscalculation, the tables of contributions have been so calculated, that if the purchaser of a *deferred life annuity* die before the time arrives at which the annuity is to commence, the whole of the money he has actually contributed will be returned, without any deduction, to his family. And if it does not exceed £50,

it is not necessary that probate or letters of administration should be taken out. But if he has left a will, or administration is taken out, no stamp or legacy duty is payable in respect of the sum so returnable, if the whole estate, &c. of the member is under £50; and again, if a purchaser is incapable of continuing the payment of his yearly instalments, he may, at any time, upon giving three months' notice, receive back the whole of the money he has paid. No annuity granted will be subject or liable to any taxes, &c.; nor can the same be transferred or assigned, but must continue to be the property, or be received for the benefit, of the party by or for whom it was purchased; but in case of the bankruptcy or insolvency of the purchaser of an annuity, the same is to be repurchased by the commissioners at a valuation according to the tables upon which the annuity was originally granted, and the money will be paid to the assignees for the benefit of the creditors.

From the above statement it will appear that any *deferred annuity*, purchased by annual or other payments, from a society established under the stat. 3d, Will. IV. c. 14, will entitle the purchaser (if he live to the age at which the annuity is to commence) to receive an annuity equivalent to the value of all his payments, with the accumulation of compound interest; if he be unable to continue his yearly instalments, he may have back all the money he has paid, exclusive of interest; and if he die before the commencement of the annuity, his family will, in like manner, receive the whole of the contributions he may have actually made previous to his decease, exclusive of interest.\*

The tables on which the government annuities are granted have been formed, as might be expected, on the soundest principles, and are entitled to the greatest respect. They relate to four kinds of benefit—deferred annuities upon the continuance of single lives, immediate annuities upon the continuance of single lives, deferred annuities to continue for a certain term of years, and immediate annuities to continue for a certain term of years. The whole are presented in a brochure quoted below.\* We extract only one specimen—namely, the terms of an annuity of £20, payable after twenty years from the time of its purchase:—

Age of the Person at the time of Purchase upon whose Life the Annuity is to depend.	Yearly Sum required.	Money to be paid down in One Sum at the time of Purchase.

CHAMBERS'S INFORMATION FOR THE PEOPLE.

BENEVOLENT PAWN BROKING.

The necessities of the humbler classes have given rise to the trade of pawnbroking, which, even when conducted, as it often is, by respectable persons, certainly forms a severe punishment upon the poor for their poverty. On this subject some exaggerated views have of late years gone abroad; but there can be no doubt that the poorest class, in pledging small articles for short periods—and the greater part of pawnbroking business appears to be of this kind—are subject to enormous extortions, calculated most materially to keep them in a depressed condition. It has been said that £3000 is annually lent by pawnbrokers in Ireland in one shilling loans, and that this sum actually produces to the lenders in a year not less than £19,500. To a poor person in want of a shilling for a week, it appears no great hardship to pay a penny for the loan of it; but when we consider that this is, in reality, borrowing money at 433 per cent. per annum, the hardship of the case is presented in its true light. Nor is the licensed and ostensible trade of the pawnbroker the worst of the case. Wherever a large horde of very poor people is collected in our large towns, there rises an unlicensed and clandestine species of the trade, conducted upon principles still more ruinous to the needy. It has been shown that there are in Glasgow many hundreds of small unlicensed pawnbroking establishments, whose extortions from the poor infinitely exceed the legal rates to which the licensed traders are restricted. The saying of Solomon, that the destruction of the poor is their poverty, was never perhaps shown in a more forcible but melancholy light than in the losses which they endure in consequence of the necessity they are occasionally under of raising money by pledges.

On the continent, the system of lending upon pledges has been practised for several centuries upon a benevolent principle. The establishments where the business is carried on are called *Monts de Piété* (mounts being a term applied to heaps of money, while the word *piété* expresses the religiously benevolent views in which the plan originated). In this case an association of benevolent persons, possessing a little capital in common stock, are the pawnbrokers, and the objects they keep in view are to make the evil of pledging as light to the poor as possible, and to apply the profits to charitable purposes by which the poor will be benefited. Here there is no extortion, no punishment for poverty, and the poor, as a body, may be said to lose nothing. In France, some abuses are said to have crept into the system; but these are not essential to it, and we have had experience nearer home how much good may be done by a well-conducted *Mont de Piété*.

The first establishment of the kind in the United Kingdom was set up at Limerick in 1837, through the exertions of a gentleman named Barrington, for the purpose of supplying funds to an hospital which he had founded out of his own fortune. The required capital was raised by debentures (or joint-stock shares) varying in amount from one to five hundred pounds each, upon which interest was to be allowed at the rate of 6 per cent. These might be withdrawn at three months' notice, or money would be advanced upon them as pledges. Mr Barrington described the following as the advantages proposed by his scheme:—

1st, The raising a capital by small debentures at a certain interest, and lending it on a greater interest, and applying the profits to the purposes of charity.

2dly, Receiving the debentures in pawn, thus giving to the depositors an advantage which they do not possess in the savings' bank.

3dly, Lending money at interest to poor persons of unimpeachable character and industrious habits, on personal security, as is done by the loan banks.

4thly, Lending money on goods, as is now done by the ordinary pawnbrokers.

5thly, In case of deserving objects, to restore the article, such as implements of trade pawned in the hour of real want, without interest or charge.

6thly, Using every precaution against receiving stolen goods in pawn.

The plan meeting with a hearty approval, a capital of above £15,000 was quickly subscribed, partly by the gentry, and partly by persons in the humbler walks of life. An active and intelligent person, who had himself been a pawnbroker, was placed at the head of the establishment, which had no sooner commenced business than it became largely supported. The following view of the transactions, from March 1837, when it commenced, up to December 1840, is given by Mr and Mrs Hall in their work on Ireland:—

Years.	Amount lent on Pledges.	Amount received for Released Articles.	Gross Profit.*
	£ s. d.	£ s. d.	£ s. d.
1837,	14,130 1 6½	9,668 11 10½	385 2 7½
1838,	17,885 13 2½	16,923 15 8½	1074 18 4½
1839,	21,091 7 8½	20,727 19 6½	1173 15 2½
1840,	25,488 6 5½	23,675 1 5½	1367 13 11
Total,	78,595 9 0½	71,005 8 7	3940 10 2½

There is no charge for tickets at this establishment; consequently if those pawns were pledged at a pawnbroker's, the poor would have to pay for each pawn a sum of one penny; if the amount borrowed amounted to 10s., twopenny; if it amounted to 40s., fourpence; therefore (not at all taking into account the low rate of interest) the saving effected by the very poorest persons is most remarkable. For instance, say that

350,000 of those pledges were under 10s., at 1d. each, £1500 0 0  
 90,000 do. under 40s., at 2d. each, 750 0 0  
 10,895 do. over 40s., at 4d. each, 181 11 8

Or a sum saved in four years on the bare item of }  
 tickets, to the very poorest people, of } £2431 11 8

If to this be added the saving in interest, we may safely calculate that nearly as much in addition is saved as the establishment is realising—as the following table will show the difference in the rate of interest, for different sums, to 10s. and £1.

Sum Lent.	Mont de Piété Interest.	Pawnbroker's Interest.	Pawnbroker's Total Charge of Interest and Ticket.
£ s. d.	d.	d.	d.
0 1 0	0½	0½	1½
0 2 0	0½	1	2
0 3 0	0½	1	2
0 4 0	1	1½	2½
0 5 0	1	1½	2½
0 6 0	1½	2	3
0 7 0	1½	2	3
0 8 0	1½	2½	3½
0 9 0	2	2½	4½
0 10 0	2	3	5
1 0 0	4	5	7

The *Mont de Piété* of Limerick having been attended with success, inasmuch that it supports the hospital for the sick poor of the city, similar establishments have been opened at Belfast and Tandragee, and the example will doubtless be followed in time on this side of the Irish Channel. In September 1840, at the meeting of the British Association held at Glasgow, an interesting paper on the subject of the Irish establishments was read by Mr H. J. Porter, from which we make the following extract:—

At the close of the first nine months of the operations of the Tandragee *Mont de Piété*, I was able to show that the borrowers from the loan fund department, on personal security, had in their possession 1189 looms, of which 612 (more than half the number) were hired at 10s. per annum. One man had at that period

\* The total number of pawns received since the establishment opened, to March 19, 1841, was 460,895.

## SOCIAL ECONOMICS OF THE INDUSTRIOUS ORDERS.

one loom, for which he had paid £12 within the previous twenty-four years, without any other alteration than that which was necessary on the invention of the fly-shuttle; and after having paid the price of four new looms in interest, he was not at that time the owner of one. Here, and in many similar cases, the Mont de Piété was the means of relieving the poor, and the owners of looms for hire began to find it difficult to let them out. One farmer, indeed, proposed to sell his stock of looms to the institution, finding the hope of his gain drawing to a close; but of course the proposal was rejected, as these old looms were incapable of producing as good a fabric as the new looms issued by the Mont de Piété.

At the period of which I speak—namely, the first nine months of operation—above 2600 loans had been granted for the following purposes:—

For provisions, - - -	Loans, 550	Amounting to	£1640
Materials for trade, - - -	158	...	402
Dealing, - - -	194	...	664
Clothing, - - -	41	...	81
Repairs of houses, - - -	51	...	148
Yarn for weaving, - - -	187	...	612
Looms, - - -	131	...	448
To pay small debts, - - -	70	...	193
To buy cows, - - -	594	...	2569
... pigs, - - -	375	...	1223
Farming purposes, seed, &c. - - -	366	...	838
Rent, - - -	77	...	252
Total, - - -	2668		£9070

In order to form some idea of the benefit derived by these borrowers, I examined great numbers of them as they appeared on the payment of the last weekly instalment. I ascertained pretty nearly the amount of money saved or realised by their having the advantage of ready money, and from these I formed an average estimate of the whole.

Oatmeal, - - -	£1100	Saving, - - -	£308
Potatoes, - - -	550	...	338
Cows, - - -	2569	Profit, - - -	1284
Pigs, - - -	1223	...	166
Dealing, - - -	664	...	166
Total, - - -	£6006	Total, - - -	£3506

Had the Mont de Piété conferred no other benefit on the country than that derived by the peasantry, in procuring their summer provisions for ready money, that alone would amply repay the directors for all the labour bestowed on the working of the institution. What were the circumstances of these 550 families in bygone summers? Many of them found it difficult to procure credit, or obtain a sufficient supply of wholesome food for the maintenance of their families; idleness prevailed, sickness increased, and not unfrequently fields were mortgaged to more wealthy neighbours, who supplied the wretched holders of two or three acres of land with the required food at an exorbitant price. Others, whose credit was good, passed promissory-notes, payable at harvest, and not unfrequently they were charged for meal 6s. or 8s. per cwt. more than the market price, independent of the expense of stamps; and it was no uncommon practice for a poor man, wanting the immediate use of a few pounds in money, to purchase oatmeal from a fore-staller of provisions, while a third person would buy back the oatmeal from the poor man at a much less price than he was charged, hand him the money, and the oatmeal would never be delivered, but sold again by the fore-staller to the next customer. The object of this transaction is evident. The value of a promissory-note for provisions would be easily recoverable at the quarter sessions, while one for cash, bearing usurious interest, would be likely to involve the fore-staller in an open violation of the law. Thus were the poor on every side oppressed: the harvest-time arrived, and the debts for the supply of summer provisions were generally first paid from the produce of the farm; too often were they unable to pay just demands of rent and other charges, while in few cases were they able to

hold over their corn till the most favourable time arrived for bringing the produce of their farm to market.

What, on the other hand, has been the experience of the last summer? Those 550 families borrowed, on moderate interest, from the Mont de Piété, £1640, and by habits of industry and increased diligence, their weekly instalments are paid; at harvest, instead of being deeply involved in debt, they owed nothing for their summer's food, and the produce of their land has in many cases been reserved for weeks, till the best price could be obtained; they are able not only to pay their rents, but to supply themselves and their children with better clothing. But other moral effects have followed. Halfpence and pence, which formerly were squandered in tobacco, snuff, and ardent spirits, are treasured up for the Monday morning's instalments, and the people are beginning to feel the value of small sums, and the truth of the old homely proverb, that 'if you take care of the pennies, the shillings will take care of themselves.'

Again, we find that £2569 has been borrowed for the purchase of cows. The benefit to the poorer classes in this particular is incalculable—the health arising from the possession of an abundant supply of milk; the improvement on their farms, by sowing green crops for the maintenance of their cows; the increased quantity of manure which is provided for the land—while it has been ascertained that in twenty weeks the generality of cows purchased have paid, by the produce of milk and butter sold, one-half of their own cost. Hundreds of families are now possessed of a cow each, and great numbers have already procured a second. As a proof of the saving habits which are promoted by this system, I may mention that a respectable person has settled in this town, whose sole business is the purchase of butter and eggs for exportation; and he finds it frequently difficult to attend to the immense influx of persons who come to sell their produce to meet their weekly instalments. One poor woman borrowed a pound; she bought five hens for 4s. 2d.; she expended 15s. 10d. in clothing; and at the end of the twenty weeks her five hens had been the sole means of paying off her debt to the loan fund.

But what is the testimony of the manufacturers in the neighbourhood! That the industry which is promoted by the necessity of those weekly instalments, and the punctuality of the weavers in returning their cloth, has already had the most beneficial effects.

And how are persons in trade affected by the operations of the Mont de Piété? I have it from the best authority, that a great increase of business has been the result, and a greater degree of punctuality in meeting all engagements on the part of the poorer classes. One class alone are suffering from the effects of the Mont de Piété, and they are little deserving of compassion. Those who live by the destruction of others, both soul and body, are not to be commiserated—those who keep open houses for the drunkard—and when they have given a poor person as much whisky as they think he can pay for, or is able to consume, turn him out, incapable of taking care of himself, and exposed to the risk of a watery grave in the next river or canal he meets—those are surely persons whose lack of business and prosperity is a blessing, and whose failure in trade must be held as a common good. I have undoubted authority for saying that the temperance cause and the Mont de Piété are going hand-in-hand; and the twopence for the morning glass, or the shilling for the night's carousal, are now carefully saved to meet the weekly instalment.

I might enlarge on the important benefits which this institution confers upon the working-class—above £1200 expended in the purchase of pigs, which are such a source of wealth to the Irish poor, being nearly fattened on the refuse from the tables of the owners.'

We must be excused for adding, in illustration, one more anecdote from a report by Mr Haynes of the

Limerick establishment:—'A poor woman, when the institution first opened, was in the habit of pledging every morning her bed-tick for two shillings and sixpence, and releasing it every evening; this she did for the purpose of purchasing potatoes from the country people, and retailing them afterwards in small quantities, at a higher price, thereby endeavouring to support her family: for this loan she daily paid the pawn-broker the sum of twopence. When the Mont de Piété opened, she, being only charged a halfpenny, saved three-halfpence daily, which eventually enabled her to raise a small stock-purse of ten shillings; and she now seldom, if ever, visits even that office.'

## THE PROVIDENT DISPENSARY.

On the subject of medical attendance, the working-man, in ordinary circumstances, may well be at a loss how to act; for, on the one hand, when he calls in a doctor on account of himself or his family, he is oppressed by the high charges for attendance and medicine; and on the other, if he resorts to a dispensary or hospital, he loses his independence. That these are evils of large amount, and widely prevalent, might easily be shown. In England, the ordinary medical practitioner charges for medicine only, but he gives much of that, and places a high price upon it. A working-man, ill for three weeks, will find, on his recovery, a bill of thirty or forty shillings run up against him, either causing him to break up his little hoard in the savings' bank, or keeping him in embarrassment for the ensuing twelvemonth. Conducted as the medical profession is in that country, it is impossible, in short, for a poor man to have independent medical attendance which he means to pay, without the most serious pecuniary distress being entailed upon him. So severely is this felt, that the resort to medical charities has of late years been rapidly on the advance in England, both involving more individuals, and individuals of a better class than formerly. In 1821, when the population of Manchester was 158,000, the dispensary patients were 12,000. In 1831, when the population was 230,000, this class of patients had advanced to 41,000; an increase of fully two to one. It was calculated in the latter year that, of all the persons ill and requiring medical advice, the dispensary patients were a majority. Similar facts are stated with respect to Leeds and Birmingham. It would appear as if a widespread demoralisation were going on throughout England from this cause. Dr Holland of Sheffield has recently published a volume calling attention to the subject. He sets out by stating very broadly, as his opinion, that the character of the working-classes in Sheffield were, at the period of his writing, undergoing a certain degree of deterioration, in consequence of so many charities, and particularly medical charities, being thrown open to them, the self-respect connected with independence being thus gradually worn away, and with it the virtues which have never yet been found to exist without it. The Infirmary, we are told, was established for the benefit of the poor and needful of all nations; but it never, our author argues, could have been designed for those who are able otherwise to obtain the desired aid. Now, however, the fact of being an operative is held as a sufficient claim. 'The artisan never dreams of the possibility of rejection on the ground of being in full and regular employment, and being amply remunerated for his labour. He applies now as naturally to the charity when he is sick as to the tailor for the repair of his clothes, with this difference, that he would be perfectly astonished were any one to hint at the propriety of paying for the favours conferred by the former.' Our author argues against the following classes at least having any right to the benefits of the institution:—Single men in employment—married men with only young and small families—men with several children but high wages—men who have several sons and apprentices working along with them—servants in situations. All of these persons, excepting the last, must be able to provide medical attendance for themselves, if they economise their

resources. He presents a hundred cases of applications, being those within the few weeks before the time when he was writing, and out of these he shows that there were fifteen young single men, all of whom but two had been in employment till the time of their illness, twelve at well-paid crafts, and one as a labourer. Eleven cases were of married persons without children; and thirty-two applicants were married, with only one or two children. In some of the latter instances, 'the only child is a daughter eighteen or twenty years of age, who has never been allowed to go out to place, or to learn any business; in others, a son apprenticed to his father, and both in regular employment. In one instance, where the wife was the patient, the daughter was in a warehouse, and the son, a youth of fourteen years of age, was a day scholar in a respectable private academy in the town. The husband had received regularly twenty-four shillings a week for the last twenty years. Many of the thirty-two cases are even more flagrant instances of impositions on the charity.'

Certainly in the whole number of applicants for relief, as far as our author has described them, we do not find that proportion of persons likely to be in necessitous circumstances which might be expected. To support his views, he brings the testimony of the house-surgeon, who, in answer to queries put to him, says, 'The character and appearance of the patients generally are very different from what they were fifteen or twenty years ago. The patients are much more respectably dressed, and in better circumstances. Many now, not from inability to walk, are conveyed to the house in hackney-coaches. . . . They apply for much more trivial ailments than formerly.' The author, from the data afforded him, speaks of females who come to the institution in elegant cloaks, shawls, and elogs. Not one-half of the applicants have the appearance of indigence. 'The frequency with which they apply for very trifling ailments, such as slight symptoms of indigestion, coughs, or occasional pain, or, indeed, for the removal of disease which just perceptibly mars the beauty of the face or neck, is evidence that their situation in life is very remote from those circumstances which entitle them to the sympathy of the benevolent. *The really poor never apply for the relief of slight and unimportant complaints.*' Afterwards he adds—'In evidence of the trifling nature of many of the medical cases, we may state that one-half are often cured in ten days, and two-thirds in three weeks.'

The results of his inquiries at the dispensary are nearly the same. The great bulk of the applicants are either themselves artisans in the receipt of good wages, or the connections of such persons. They come in respectable apparel, and when visited at their homes by the medical men, are found to possess every appearance of domestic comfort. Recommendations from subscribers to the institution are necessary to procure admission; but these are given, in seven cases out of ten, by persons who have no knowledge of the circumstances of the applicants. 'A gentleman who, from his position in society, is often applied to, informs us that he always refuses, unless the individual bring a letter from his employer, stating that he is a necessitous object; and though promising to give a recommendation on this condition, *not one in twenty returns to receive it.*'

Facts still more remarkable are brought out by Dr Holland. 'The distresses of a community,' he says (meaning such a community as that of Sheffield, upon which he founds his opinions), 'will be admitted to bear a strict relation to the state of trade. When this is extremely depressed, many hands are thrown out of employment. When the trade is good, the demand for labour is great; wages advance, and the blessings of plenty are universally experienced. The amount of misery or destitution cannot be the same in these very different circumstances. It cannot be a fixed quantity floating in society. The idea is preposterous; and yet, if the registered demand for charity be any criterion of the misery existing, there is indeed a quantity subject to scarcely any variation whatever.'

## SOCIAL ECONOMICS OF THE INDUSTRIOUS ORDERS.

From midsummer 1835 to midsummer 1836, between which periods trade was better in this town than it had been known for years, the number of patients admitted on the books of the Infirmary was 3126. From midsummer 1836 to midsummer 1837, between which periods trade was exceedingly depressed, the number was 3431, being an increase only of 305 patients. Between the former periods the number of patients on the books of the Dispensary was 2888. Between the latter periods—that is, from July 1836 to July 1837—the number was 2576, being less by 313 patients. According to these returns, there were *eight patients more during a prosperous state of trade, recipients of medical charity, than during the severe depression of it.*

Dr Holland elsewhere states that healthy seasons are marked by no diminution of the number of applicants. 'We hesitate not to assert that, during the last twelve months, there has been less disease in this town and neighbourhood than has been known for many years, and yet during this period the demands on medical charities have increased.'

As a remedy to these evils, some benevolent persons, with the co-operation of a few of the more liberal of the medical profession, have instituted what are called *Provident Dispensaries*, the main feature of which is, that the working-man contributes a small sum weekly from his earnings, to entitle him to medical attendance and the requisite medicines, in the event of illness entering his household—the united contributions of a few hundred members being sufficient to engage a respectable physician, and defray all the other expenses. Such institutions have been tried with marked success at Coventry, Derby, and some other places. They are limited strictly to the class who are unable to fee medical attendants in the ordinary way, but who are yet anxious to keep themselves in all respects above the condition of paupers. Individuals wishing to belong to the provident dispensaries must join when in good health, as the object is in reality an 'assurance' against sickness, and the provident character of the institution could not otherwise be maintained. One penny a week is paid for each adult of the family, and a halfpenny for each dependent child. Individuals of the more affluent classes contribute without the design of benefit for themselves, in order to encourage the institution, and from them in general the directing body is chosen—the only part of the arrangement which we cannot fully approve of. From the proceeds a medical man is fed, and medicines are provided; and it is remarkable that a thousand sick persons connected with a provident dispensary have been found to cost considerably less than a similar number of patients resorting to the medical charities. The tendency of such institutions to maintain the moral uprightness of the working-classes is obvious; and it is already proved that, wherever they have been planted, applications for parochial relief have been diminished. It is to be lamented that medical men have a prejudice against them, probably from no other cause than that small copper sums are concerned in supporting them. But surely it is better even for medical men that the humbler order of patients should pay something within their means, and that regularly, than only pay in a few instances, and in others either resort to charities or leave a large debt unliquidated. Of the same na-

ture with these dispensaries is the practice, now pretty extensively adopted at public works where a great number of hands are employed, of compelling each workman to deposit a certain amount of his wages for the purpose of medical aid—a practice which has been attended with the best results in many instances which have come under our own knowledge.

Whatever may be the sentiments of the profession upon this point, it must be evident to all that, for the working-classes themselves, the provident dispensary is a most unexceptionable species of institution. It carries them over one great difficulty in their career with the preservation of their independence; it does more, for, being on the assurance principle, it encourages habits of foresight. Some other advantages presumed incidental to it are thus stated by Mr P. H. Holland, in the pamphlet above quoted:—'Assistance in sickness is much more easily accessible in provident than honorary dispensaries. The patient need not lose time, or degrade himself, by running about to beg a recommendation, but applies at once for an attendance ticket, and puts himself under the care of the medical officer of his own choice; in fact, procures assistance just as readily as the richest of the land. Consequently, as I am informed by Mr Nankivell, at the Coventry Dispensary, the cases being seen by the surgeons at the very outset, the probability of a successful result is much higher than in ordinary dispensaries: for instance, at Coventry, they have lost, out of 6094 patients attended, 92, or 1 in 66; at the Chorlton-upon-Medlock Dispensary, in the same period, out of 6438 patients admitted, 210 died, or 1 in 30.6. All who have had experience in ordinary dispensary practice, will know the advantage of getting the cases early; for, at present, very many patients, rather than undergo the trouble, unpleasantness, and painful sacrifice of honest pride, will not apply for a recommendation until they dare delay no longer; consequently, many cases are not under treatment until the only time at which it could be available is past, and it is this which renders dispensary practice so harassing.

It is probable, nay certain, that the large number of patients, in proportion to the deaths, is in a great measure owing to the very easy access to a provident dispensary, causing many to apply on very trivial occasions; but who shall say how many of these trivial cases would have become serious, or even fatal, if neglected! But this partial explanation will not at all account for the very gratifying result which, by the following analysis of the reports of the Coventry Self-Supporting Dispensary, I have elicited—namely, *that the average mortality among the members of that dispensary is considerably less than the average mortality of the country generally.* This is the more remarkable, as it is fair to presume that the sickly will be more ready to subscribe than those in robust health, and therefore we might have expected a mortality somewhat greater than the average. The mortality of a town like Coventry is about 1 in 50 per annum. The following table exhibits the number of members, upon the presumption that each on an average contributes at the rate of 3s. per annum, which must be very near the truth, as adult members pay one penny per week, and children a halfpenny, while any more than two in a family, below twelve years of age, are not charged:—

Years.	Calculated Number of Members on the Average of the whole Year.	Patients Admitted.	Deaths.	Computed Number of Members to each Death.	Number of Cases to each Death.	Amount of Honorary Subscriptions and Donations for Expenses of the Establishment.			Amount of Members' Subscriptions, from which Fund the Drugs are paid for, and the remainder.			Paid to the Surgeons.		
						£	s.	d.	£	s.	d.	£	s.	d.
1834,	2670	1568	90	183	77	143	6	6	400	12	0	268	0	0
1835,	2771	1565	27	109	59	114	4	0	415	13	1	287	2	0
1836,	2650	1490	17	155	83	194	6	2	897	9	3½	263	3	0
1837,	2614	1551	28	93	55	101	13	6	892	2	1	261	15	0
Averages,	2676	1523	23	121	68	120	17	3½	401	9	1	269	15	0

The average annual mortality among 2676 of the population, taken promiscuously, would be about 53; whereas the mortality among the Coventry Dispensary patients has been only 23. We must not suppose that the dispensary is saving lives at the rate of thirty a year, for much of this difference of mortality must be attributed to the circumstance of the members of the institution consisting almost entirely of the most frugal, industrious, and prudent of the work-people. Something ought perhaps to be attributed to there being probably a disproportionate number of adult members. "But if we are ever warranted," says Mr Nankivell in a letter to the author, "in ascribing to medical means the saving of life, most surely are we so among the patients of a self-supporting dispensary, where the members have medical advice at the very outset of disease, more promptly perhaps than any other set of persons in the country."

## MINOR ECONOMIC FUNDS.

The Hon. and Rev. S. G. Osborne, of Stoke Vicarage, Buckinghamshire, has published an account [*Hints to the Charitable.* Price 1s. T. and W. Boone, London.] of several small economic funds, which have been formed in his parish—a large agricultural one—for the benefit of the humbler classes, apparently in a great measure by the active and well-directed zeal of the author himself. They are worthy of notice.

One of these is a *Coal Fund*. The poor in Mr Osborne's district are generally ill off for coal during the winter months; and when the weather is unusually severe, it is found necessary in many parishes to subscribe to obtain for them a portion of that domestic necessary. In Stoke parish, the poor are induced to commence in June paying one shilling a week each into the parson's hands, until twelve shillings have been paid. Coal is there generally from 1s. 1d. to 1s. 5d. a bushel; yet the managers of the fund undertake that each person shall have twelve bushels of coal delivered to him, during the course of winter, at his door, free of all charge (a sack of three bushels being given every three weeks four times). The extra money required is contributed by the benevolent people of the neighbourhood. Charity is here partially employed; but it is to be remembered that the benefit is conferred upon a class who might otherwise be entirely dependent in this respect. Mr Osborne considers it a great matter that the poor are induced to contribute the larger share of the funds: their spirit of self-dependence is encouraged to that extent. The reverend manager of the fund endeavours to save a little in good years, in order to be the more able to succour the poor in bad ones. The poor complain of this, but he waits patiently till a bad year comes to show them the good of the system. In the severe winter of 1837-8, he had £24 in hand. "We thought the severity of the season such an extreme case, that we ought to do something more than usual for the poor. Accordingly, we took a part of the balance, and bought 114 sacks of coal, some of which we gave away, but sold the greater part at the low price of sixpence a sack. The poor were thus taught the advantage of having saved this balance, and we had the satisfaction of affording a most seasonable relief, without begging for a single sixpence from any one." It may be presumed that the parties on the coal fund will be more careful of fuel thus obtained than of that which is given them for nothing. "They can look forward to the winter," says Mr Osborne, "with one heavy care for it removed. When the winter comes, with little or any addition, the tired labourer may even find a comfortable fire at home to spend his evenings by; he is not forced to go to the beer-shop to warm himself."

The *Wife's Friendly Society* is designed to enable married women of the poorest class to have a small fund which they can draw upon, to defray the expense of a proper medical attendant at their confinements, and furnish some of the comforts required on those occasions. Generally, this class of persons have no provision for such occasions, and the consequences are

that they depend on charity, and sometimes suffer from the indifference which the midwives in that case employed are apt to feel where their care is not to be remunerated. A poor woman recommended to the *Wife's Friendly Society* pays 2d. weekly for a year to the treasurer (the vicar's wife), making 8s. 8d. in all. To this the society from charitable contributions adds 2s. 10d., making 11s. 6d. If she is confined that year, she gets an order for 10s., which serves as payment for her medical attendant. The remaining 1s. 6d. serves to furnish gruel and other little comforts—a small sum for such a purpose, but better than nothing. The person who recommended the member guarantees that, after this payment is made, she will continue to pay her weekly twopences till the end of the year. Should no confinement take place, the money is spent on clothes.

In the case of the *Penny Clothing Fund*, the proportion of charitable contribution is greater than in any other of Mr Osborne's schemes. The object is to encourage the poor to exert themselves to furnish decent clothing to their children. A benevolent person pitches upon some child belonging to a poor neighbour: the patron and the child each pay 1d. weekly into the fund; that is, 8s. 8d. annually. Some persons take two, three, or more children under their care. Mr Osborne speaks of 150 in all his parish being clothed by these means in one year. "The buying of the clothing is thus managed: a linen-draper attends with his shopman on a given day at the expiration of the year, with a large supply of all such articles of clothing as the poor most need for their children; the school-room is allotted to him as a shop for the day. In addition to the linen-draper, we have a person over from a neighbouring market-town, whose business it is to deal in ready-made clothing and shoes for boys; he has a room adjoining the school for his shop. Each lady (these clubs are almost always wholly supported by the female sex) appears with the children she has put in, together with their parents; they are served in turn, and it is the lady's duty to see that they have their 8s. 8d. worth of goods. The pence are received from the children weekly at the school; from the persons putting them in, at the end of the year.' Clothing for children being one of the things which the poor, amidst the various difficulties which beset them, are least apt to provide for, we can well believe that this fund is likely to do much more good than the practice of presenting blankets at Christmas—a blanket being an article which the parent couple feel the want of pressingly themselves, and are therefore eager to provide from their own means.

The *Endowment Society for Children* is the last of Mr Osborne's parochial schemes which are different from those already developed in these pages. The object here is to make a provision, by small payments, in the course of a few years, for an event connected with a child which will make a small sum of money necessary—as, for instance, to put him (or her) out to service or apprentice him, or to furnish him with tools for his trade when his apprenticeship is expired. One shilling, one and sixpence, and two shillings, are the various sums received, and they may be for two, four, or six years. The principle is the same as in a savings' bank, but the money is devoted to a particular object, and that a very interesting one, and a stimulus to saving is added. The managers of this fund place the money collected in the savings' bank; in the event of the nominated child dying, another is taken, or the money given back.

For further information on these economic institutions, we refer to Mr Osborne's little volume. It may be mentioned that he has published other pamphlets (T. and W. Boone, London) connected with the subject of this sheet, and all of which seem to us well worthy of the attention of those who aim at benefiting the poor by evoking their own best powers in their own behalf. Politically, socially, or morally, a man can be said to fulfil his proper function only when he trusts to his own right arm for the support of himself and family, and leans upon no one save in the general sense in which mankind are all mutually dependent.

## POPULAR STATISTICS.

STATISTICS is a science of comparatively recent date, but it is one which promises to be of considerable service to mankind. Whatever can be ascertained by *taking down numbers and instances, and making summaries of them*, may be said to be a proper object for this science. It is usually applied to such matters as the amount of population, the rate of mortality, the progress of commerce, manufactures, and agriculture, the increase or diminution of crime, the state of education, and the comparative social condition of the several classes which compose any given community. The benefit of coming to correct reckonings about these matters must be obvious; but we shall cite one instance to make it quite clear. From accounts which have been kept of the burials in England for the last fifty years, it appears that the rate of mortality (or number who die yearly in comparison with the whole population) diminished regularly down to 1821, but has since then been a little on the rise; showing that the condition of the people at large (mortality depending on condition) was improving till that time, but has since been slightly declining. When such a fact as this is ascertained, statesmen are put on the alert to discover, and, if possible, remove the causes. Thus it is seen a nation may be much benefited by taking a census, and the keeping of a correct register of deaths. The value of statistical operations, then, is manifest. Statistics may be said to be the account-book of a nation for ascertaining the condition of its affairs. One which keeps no statistical records may be said to be like a merchant who transacts business without keeping a ledger, or ever coming to a balance.

Statistics bears in a similar manner upon many of the interests of private life: of this we trust to be able to give some notable instances in the sequel. It is one of its least utilities, that it tends to substitute real and distinct knowledge in many matters for vague and general impressions. There are many things which, to the uninstructed mind, can only be mentioned to create a feeling of doubt—for example, the comparative likelihood of life in men and women. Ask an uninstructed person whether women or men in general live longest, and, at the best, he will only be able to answer from some obscure notion in his mind, the result of a few observations which he has happened to make. Statistics has ascertained, though only within the last fourteen years, that female life is *better*—that is, of longer duration, than male. Here is a thing which no individual could ascertain for himself, and about which all was doubt for hundreds and thousands of years, settled at last by statistics. We have now the satisfaction of knowing the fact distinctly, instead of only conjecturing, and perhaps wrangling about it.

On some of these vague questions proverbial wisdom is found to have made a conclusion for itself. For example, this oracle has long been clear, that an open winter is the most fatal to life, and that more die of surfeit than of want. Statistics finds both of these, and many like conclusions, to be exactly the reverse of the truth. It has here corrected decided error, which is better still than giving distinct knowledge where formerly there was only doubt. It is observable of almost all such proverbial notions, that they appear to have proceeded upon a principle of contradiction or paradox, the contradiction being generally to what is the most likely conclusion of the mind upon the subject. For instance, want seems at first sight a more deadly thing than over-abundance; but then it is also found, if we pause and look narrowly, that it is possible also to die of cholic and of pampering. The clownish oracle has the same wish to be novel, original, and striking, which is so much the bane of higher and more aspiring philo-

sophy, and it decides that the most mischief is done by the less obvious evil. To put an end to such modes of judging, by adducing the undeniable testimony of figures, is, we humbly submit, a worthy service, and this service is rendered by statistics.

There is one other service which statistics has rendered, of a more remarkable, though perhaps less directly useful, kind than the above. Almost all the occurrences which depend on the human will happen irregularly as to time, as far as an individual is concerned. A man commits some particular crime which he is not likely ever again to commit in his life—for instance, an assault with violence. It was, to all human apprehension, the merest chance which brought him into the circumstances which provoked or prompted him to commit the offence. Yet, strange to say, there is no offence so accidental as to individuals, or so unlikely to occur above once in an ordinary man's lifetime, but what statistics finds it to occur, with the greatest regularity, in a certain range of individuals and within a certain range of time. The returns of a particular crime, in such a country as England or France, are nearly the same for each successive year. In all classes of occurrences which appear occasional as to individuals, the same uniformity is observed when we go to sufficiently large numbers: even in the number of letters put into the post-office without addresses, there is a precise uniformity, if we take the office of a large city, and reckon year against year. Thus to find an order in the most casual of things, even in the wayward and fleeting movements of the mind, affords highly-interesting matter for reflection.

Statistical science has its quicksands and difficulties as well as its triumphs. Often, when an extensive range of facts has been accumulated, all, as is thought, tending to confirm a certain view, there may still be room to contend that they lead to directly opposite conclusions, or that they show the presence of totally opposite causes from those presumed to exist. There is a tendency in those who pursue the science to make inferences in accordance with their own prejudices, or to seek only for facts by which these are favoured: on fact, to pursue the prejudiced system of planting a theory, and then setting out in search of facts to support it, instead of the more philosophical method of first collecting facts from which to deduce a sound and practical conclusion. Such errors are particularly likely to be made in subjects where many causes are presumed involved, and which are so extensive that it is difficult to command a general view of them. As an example, we have only to remind the reader of the various notions which are usually entertained as to the causes of any distress which may take place throughout the country. The higher class of statisticians usually, however, are cautious in drawing inferences and tracing causes, believing it to be their best course, in all doubtful cases, to restrict themselves to the collection of facts. 'We are employed,' say the members of the Statistical Society of London in their Report for the year 1848-49, 'in narrowing the circle within which the final truths must lie, rather than in an attempt at once to seize them, in which we should fail, to the loss of that credit which is due to our exertions.' In this arduous and commendable labour many individuals are now engaged: Britain has her Office of Statistics; France her Bureau de la Statistique Générale; Belgium her Central Commission of Statistics; and, in fact, all the principal states of Europe have now their central offices in imitation of our own. Without a sustained effort of this kind, correct data can never be accumulated; and without a broad basis of facts, all attempts at generalisation are worse than useless.

# CHAMBERS'S INFORMATION FOR THE PEOPLE.

## BIRTHS.

### Proportion of the Sexes.

Many millions of observations have been made upon births in the various countries of Europe, from which one uniform result appears, that about 21 boys are born for every 20 girls. The proportion in different states is here exhibited:—

STATES AND PROVINCES.	Males to
	100 Females.
Russia, . . . . .	106.91
The province of Milan, . . . . .	107.61
Mecklenburg, . . . . .	107.07
France, . . . . .	106.53
Belgium and Holland, . . . . .	106.44
Brandenburg and Pomerania, . . . . .	106.27
Kingdom of the Two Sicilies, . . . . .	106.18
Austrian Monarchy, . . . . .	106.10
Silesia and Saxony, . . . . .	106.05
Prussian States ( <i>en masse</i> ), . . . . .	105.94
Westphalia and Grand Duchy of the Rhine, . . . . .	105.86
Kingdom of Wurtemberg, . . . . .	105.69
Eastern Prussia and Duchy of Posen, . . . . .	105.66
Kingdom of Bohemia, . . . . .	105.88
Great Britain, . . . . .	104.75
Sweden, . . . . .	104.62
Average for Europe, . . . . .	106.

Further inquiries have shown some curious modifications of the law which seems to preside over this part of the natural economy of the world. In illegitimate births, the over-proportion of boys is somewhat less, nearly approximating in some countries to a par with the number of girls. In France, says Mr Babbage, 'it was observed a few years ago, that out of 6,705,778 persons born, legitimate and illegitimate, there are 3,458,965 males, and 3,246,813 females, or nearly 16 males to every 15 females. Out of 460,391 illegitimate children, there are 235,951 males, 224,440 females. From these data it follows that, in France, for every 100,000 legitimate female children, there will be 106,534 legitimate males; but for every 100,000 illegitimate females, there will be born only 105,128 illegitimate males; so that the probability of a child about to be born being a female is greater if it is illegitimate than if it is legitimate.' It has likewise been found that there is a less over-proportion of boys from marriages in which the husband is the younger party, and in cases also where both parties are extremely young. If the husband, therefore, be much the younger party, we expect his family to consist chiefly of girls; and the same where both husband and wife are much under the age of twenty or twenty-one.

The average fruitfulness of marriages is not clearly ascertained, in consequence of imperfect registrations; but it is considered by Mr McCulloch to be in England in the ratio of 4 children to each marriage. The accounts of the Registrar-General for the six years ending 1842 give the proportion as 41.56; this, however, is too high a ratio, seeing that it includes illegitimate as well as legitimate births.

### Legitimate and Illegitimate Births.

The proportion of illegitimate to legitimate births is a point of great importance in political economy as well as morality, for illegitimate children are generally a burthen to the state, and have an inferior chance of growing up useful citizens. It is also a fact ascertained by statistics, in opposition to common ideas, that such children have generally less of the elements of health and vitality than other children. The proportion of illegitimate to other births is—for France, 1 to 12.5; Prussia, 1 to 13.1; England, 1 to 14; Sweden, 1 to 14.6; the preponderance of morality thus appearing in favour of the two latter countries. In cities the proportions are strikingly different. In Paris, for 28 legitimate there are 10 illegitimate births; in other and stricter terms, the latter are in proportion to the former as 1 to 2.84. In Stockholm, from the report of

a recent traveller, the proportion is 1 to 2.3; that is, nearly a third of the children born in that northern capital are illegitimate. In Berlin, the proportion has increased, since 1790, from 1 to 9 to 1 to 6.

### Still Births.

The proportion of dead-born to live-born children is found in European cities to be about 1 in 20, but in the country not above half that amount; showing apparently that rural life is most favourable to the health of women during pregnancy and to successful parturition. It is worthy of remark, that more male than female children are still-born; the proportion in Western Flanders has been found as 14 to 10, and the same result appears in some other countries. At Gottingen, in 100 births, 3 were of legitimate, and 15 of illegitimate children.

### Effects of Scarcity.

Times of scarcity and privation tend to reduce the number of marriages, and also of births, though generally not immediately. The great scarcity which occurred in England at the commencement of the present century, occasioned a diminution in the number of marriages to the extent of about 18 per cent., as compared with the previous years of abundance. In the Netherlands, wheat was at 9.56 florins per hectolitre in 1816, and the births in the year 1818 had sunk, from a previous higher number (195,862 in 1815), to 183,706; in 1819, wheat had fallen to 3.72 florins per hectolitre, and the births, two years thereafter, rose to 210,359.

### MARRIAGES.

The number of marriages per annum in proportion to the population, and the ages at which marriages take place in both sexes, form interesting subjects of inquiry.

In England and Wales, the number of marriages registered was 111,481 in 1837-8; 121,083 in 1838-9; and 124,829 in 1839-40. The number is believed to have been less in the first of these years than it otherwise would have been, in consequence of a popular error which induced parties to hurry on their nuptials before the commencement of the operation of the registration act. Taking the two latter years against each other, we find an increase of 3246 marriages upon the latter; but this is liable to a reduction of 1700 on account of the increase of population; so that, on the same number of people in 1838-9 and 1839-40, there was an increase of marriages, strictly, of about 1500. While there was thus an increase upon the whole country, the greater portion of the manufacturing districts in the west of England, where at this time commercial difficulties existed, showed a decrease, amounting in some districts to 6 per cent.; and in Manchester and Salford to no less than 12 per cent.

In England and Wales, the proportion of marriages to the whole population seems to have been diminished during the last fifty years. It is calculated that, in the period 1796-1800, there was 1 marriage annually to every 123 persons; in the period 1816-20, 1 for every 127 persons; in the period 1826-30, 1 for every 128. This seems to be nearly its present proportion.

Some years ago, Mr Finlaison made a calculation of the ages of women at the time of their marriage from an assemblage of 878 cases, which was too small for very satisfactory results. Enlarging the number to 1000 for the sake of arithmetical distinctness, he found the following to be the various ages at marriage:—

Age.	Age.
14 to 15, . . . . .	28 to 29, . . . . . 45
16 . . . 17, . . . . .	101 30 . . . 31, . . . . . 18
18 . . . 19, . . . . .	219 32 . . . 33, . . . . . 14
30 . . . 21, . . . . .	233 34 . . . 35, . . . . . 8
22 . . . 25, . . . . .	101 36 . . . 37, . . . . . 9
26 . . . 27, . . . . .	60 38 . . . 39, . . . . . 1

A calculation upon which more dependence may be placed was made by the Registrar-General, upon the basis of 10,019 marriages which occurred in different parts of England in 1838-9, reducing the proportions to 10,000. The following table gives the results:—

POPULAR STATISTICS.

Ages.	Men.			Women.			1838-9.	
	Bachelors.	Widowers.	Total.	Spinsters.	Widows.	Total.	Men.	Women.
15 and under 20, . . .	329	...	329	1815	1	1816	877	1416

Totals, . . . . .	8833	1187	10,019	9238	781	10,019	10,000	10,000

According to the preceding table, the average age of marriage in England is—for men, 27·4 years; for women, 25·5 years. It presents, upon the whole, a favourable view of the prudence of the English people as to marriage. Only 2·3 per cent. men, and 13 per cent. women, are wedded under the age (legal non-age) of 20. About one-half of both sexes are married between 20 and 26. Only about three-fourths of a per cent. of first marriages are contracted by either men or women after they reach the age of 44.

It seems to be clearly ascertained, that the tendency of the sexes to marriage is liable to be modified by a number of conditions. Above a certain point in education, comfort of circumstances, and respectability of position, the tendency diminishes, and we see men and women of the middle and upper classes living contentedly in celibacy, from a dread of the increased expenses of matrimonial life. Below that point, the tendency increases, from opposite causes. It is observably more powerful amidst a dense operative population than amongst a scattered one, and it reaches its extreme in the half-destitute class, however otherwise circumstanced. Statistics affords us some information respecting two widely-separated parts of the earth, one of which is remarkable for early and numerous, and the other for rare and long-delayed marriages—Glasgow and the parish of Montreux in Switzerland. In Glasgow, the marriages were, in 1839, in the proportion of 1 to 112 of the population; and this ratio rises much higher in unusually prosperous years, as, for instance, in 1825, when it was 1 in 84. Montreux is too small a district to afford basis for a calculation of this kind; but the people, who are all small labouring proprietors, are remarkable for postponing marriage to a late age, the average ages of men and women being 30 and 26·75 respectively. In Montreux, the births are as 1 to 46 of the population, and the deaths as 1 in 75, both uncommonly favourable proportions. Those of Glasgow will be found very different. It seems incontestable, indeed, that a multiplication of marriages in most situations is attended by an increase of mortality, and particularly an increase in the mortality of the young during the first years of childhood. We trust we may here venture upon a few general remarks of a social tendency with respect to marriage amongst the industrious orders.

It is a familiar saying among the industrious orders, that 'the mouth never comes without the meat for it;' by which they encourage themselves to marry, or console themselves when, having married, they find their family increasing upon them more rapidly than they can well see how they are to provide for it. This fallacy has been in some measure brought to the test of figures. Dr James Philips Kay, an assistant Poor-Law Commissioner, instituted in the year 1838 an inquiry into the actual income of agricultural labourers in the counties of Norfolk and Suffolk. Returns to the circulars which he issued for this purpose enabled him to make the following abstract of the annual earnings of 539 families;—

	Average annual income.
36 single men,	£25 1 4½
64 married men, with no children at home,	30 12 10½
166 married men, with 2 7-8ths children, all under 10 years of age,	32 13 2
120 married men, with 3 7-10ths children, 1 of whom above 10 years,	35 9 0½
92 married men, with 4 9-10ths children, 2 of whom above 10 years,	40 10 1
44 married men, with 5½ children, 3 of whom above 10 years,	45 11 9½
15 married men, with 7 children, 4 of whom above 10 years,	50 18 6
1 married man, with 5 children above 10 years,	42 12 0
1 married man, with 6 children above 10 years,	52 0 0

The first question suggested by this table is—How much of the increased income of the men with families was owing to their working more steadily, from a sense of their families being dependent upon them? and how much to the earnings of their wives and children flowing into the common stock? This does not directly appear, but the returns afford means of arriving pretty near the truth by calculation. Out of the 539 male heads of families, 475 earned annually by daywork £7382, 5s. 2d., which gives the average annual earnings of each man by this means at £15, 10s. 10d., or within a fraction of 6s. a week. The earnings by taskwork are specified in 350 cases, and amount in all to £5018, 17s. 7d., which gives the average earnings of each man by this means at £14, 6s. 10d. annually, or 5s. 6d. a week. There are enumerated at least 286 cases in which the labourer obtained earnings in both ways; but it would give too high an average to add the two sums together. We are enabled to approach to the truth in another direction, by deducting the amount of earnings said to be made by women and children from the average incomes of the families. The sum of all the annual earnings of all the families (counting each single man as a family), in the table given above, is £19,129, 16s. 5d.; and this gives an average annual income of £35, 10s. The men are stated to have earned on an average £5, 8s. by harvest work, in addition to their regular wages: the average earnings of wives are about £2, 12s. 7d.; of children able to work, £8, 1s. 11d.; and the value of gleanings by the younger children is £1, 1s. 10d. Deducting these sums from the average family income, leaves £17, 4s. 4d. for the average annual earnings of the man by ordinary task and daywork; and this, when we take into consideration the number of men, and the amount earned in the year by these routine kinds of labour, seems by no means an improbable estimate. This £17, 4s. 4d. added to the £5, 8s. of harvest wages, gives £22, 12s. 4d. as the average annual earnings of a man (7s. 8d. per week), or only 13s. more than the average earnings of the unmarried men; from which we infer that the additional income of the married men is derived from the labour of their wives and children.

Deducting the earnings of the unmarried men from the whole amount, and dividing the remainder by

the number of married men, we get an average of £36, 7s. 2d. for the annual earnings of each married man and his family. But whereas the £25, 1s. 4½d. is allotted exclusively to the maintenance of one person only, the income of £36, 7s. 2d. has to provide for an average of 3·5 persons. Unless the married man can support a wife and 3·5 children upon £11, 5s. 9½d. per annum, he must dispense with luxuries, comforts, it may be conveniences, in which the unmarried man can indulge. And the average income is raised to this height by taking into account those families which, having three, four, five, and six children above ten years of age, have an average income of about £45 per annum. To reach this highest grade, even they must have passed through years of greater pinching, when their children were growing old enough to take care of themselves and earn a little. The mill through which they have been ground may be conceived by taking into account these facts. The average annual earnings of a wife with no children were £3, 8s. 9d.; of a wife with 2½ children under 10 years of age, £2, 9s. 10½d.; of a wife with 3½ children, one above 10, £2, 11s. 7½d.; of a wife with 4½ children, two above 10, £2, 5s. 7½d.; of a wife with 5½ children, three above 10, £2, 19s. 1d.; of a wife with 7 children, four above 10, £2, 3s. 10d. From which it appears, that a woman with a family is only able to earn about two-thirds of what a woman without that encumbrance can earn. The earnings of the children also fall to be taken into account. In families with 2½ children, none of whom were above 10 years of age, the average annual earnings of each child were 15s. 3½d.; in families with 3½ children, one of them above 10, the average earnings of each child were £1, 1s. 9½d.; in families with 4½ children, two above 10, the average earnings of each child were £1, 13s.; in families with 5½ children, three above 10, the average earnings of each child were £2, 2s. 5½d.; in families with 7 children, four above 10, the average earnings of each child were £2, 17s. 8d. An additional head of income must, in strict accuracy, be mentioned—namely, the value of corn gleaned by the children. As might be expected, the amount increases with the number of children; but as the age of the latter does not much affect their ability to glean, the increase is very gradual, and of small amount:—

VALUE OF CORN GLEANED.

Families.	Average Annual amount to each Family.
46 with no children, . . . . .	£0 17 10½
110 with 2 7-8ths, all the children under 10, . . . . .	0 18 7½
97 with 3 7-10ths, one child above 10, . . . . .	1 0 6½
85 with 4 9-10ths, two children above 10, . . . . .	1 5 6½
37 with 5 3-4ths, three children above 10, . . . . .	1 9 6½
13 with 7, four children above 10, . . . . .	1 6 9½

These figures demonstrate that the married labourers incurred in general an additional amount of expenditure, which their additional income by no means compensated. The kind of expense incurred by the married men, as well as the amount, is different—childbed outlay, education of children, and the increased chances of sickness as the numbers of a family increase. It must be remarked, too, that the cases selected to illustrate this point are, in so far as the unskilled labourers of the country are concerned, favourably circumstanced. Of the 539 families enumerated, 397 had gardens (averaging 19½ rods); 136 had some fuel free of charge; 259 had each a pig; and 20 each a donkey. The average of their house-rent (£3, 11s. 4½d.) did not rise above the average level throughout the country; while in a rural district provisions are cheaper than in towns. Above all, the engrossment of their parents' attention by labour was not so dangerous for the children as in densely-populated towns, where, when left at all to themselves, they are in constant danger of falling in with instructors in crime, and are placed in a situation where greater opportunities present greater temptation. If, then, among individuals who, for the class to which they belong,

may be considered in easy circumstances, marriage be a step which must render increased exertions and self-denial necessary, what must it be for those who are in more difficult circumstances! Let the experience of a committee appointed in Glasgow in 1837, to afford relief to the industrious poor in a season of severe pressure, answer the question:—

Out of 3072 adult males who applied for relief and were furnished with work, 2273 were married. The number of the children of those married applicants was 6302, or nearly 3 children to each family. No less than 532 of those married men were under 30 years of age: of the children, 3994, or nearly two-thirds, were under 10 years of age. Of the 2273 married men, 2171 were weavers; and the account given by Mr Charles Baird, in a paper read before the Statistical Society of London, in February 1838, of the condition of that class even in times of no extraordinary pressure, may serve to show with what prospects they had rushed upon the hazardous responsibilities of marriage.—‘The great bulk of the weavers in Glasgow and its suburbs,’ says he, ‘are in extreme poverty. Their wages which, even in 1819, were as low as 12s. gross, or 10s. 8d. nett (the deductions being for loom-rent, winding, &c.), now average only 8s. 4d. gross, or 7s. nett per week; and even for this miserable pittance they are obliged to work from 14 to 16 hours per day. Their houses, which are generally in the suburbs, are of the poorest description, barely furnished, and the food and clothing of the inmates, as might be expected, not only of the plainest description, but also quite inadequate.’ It is apparent, that they who, in the best of times, can barely procure a subsistence by 14 or 16 hours of daily toil, must, by the slightest and shortest stagnation of trade, be reduced to destitution, and, under such circumstances, to incur the charge of a family is madness.

This is a consideration which has of late been much urged upon the poorer classes—not always, it is to be feared, in the most judicious manner. Leaving out of view that the deductions of Malthus (see POPULATION, No. 83), whose disciples have been the most busy in giving this kind of advice, are based upon statistics remarkable both for vagueness and inaccuracy, and tainted by the polemical bias of his mind when he first published them, the form in which they have generally been submitted is of all others the least calculated to make an impression upon uneducated minds. Abstract reasoning, geometrical and arithmetical ratios, convey no tangible ideas calculated to influence their conduct; and the subordinate discussions into which some of these philosophers are fond of diverging, repel by inspiring disgust. Advice may be sound, however, although it be given in an uncouth form and by unamiable persons. In regard to improvident marriages, the industrious poor would do well to consider.

Marriage has its attractions, and, what is more, its moral advantages. It is the only institution which reconciles with the stability and good order of society one of the strongest impulses of our nature. If it add in some degree to a man's expenditure, it repays him by conferring blessings unattainable without it. The unmarried man is isolated; the married man, if ordinarily well-conducted, has a permanent hold on the affections of a portion of his fellow-creatures. A judicious selection of a helpmate ensures him comforts at home which no price could otherwise secure for him. If he act wisely, he will find his family affections the best of moral teachers. The state of marriage is honourable, and is desirable. And now let us turn to the considerations which every man, properly desirous of entering such a state, ought to weigh duly beforehand:—It is mainly by her domestic industry that he ought to expect his wife to contribute to his comfort—by her judicious aid in making what he earns to go as far as possible. She may at first have some time to spare for earning, but when a family comes upon her, that and the household together will take up by far the greatest part of her time. Children must for a time be a mere draft upon his industry. Great and just complaints have been raised of the ex-

treme labour exacted from infants in factories. Granting that the employers of such infants are culpable—what are their parents! The father who allows his child to be precociously employed in labour beyond its powers, calculated to destroy it physically and morally, and render all its future life one long disease, is consenting to the crime. There is no legal pressgang to sweep children into factories. A conscientious man, who contemplates marriage, will take these facts into consideration, and ask himself whether his position and prospects are such as entitle him to expect to be able to support a wife and children as they ought to be supported, for a number of years. He must estimate the possible earnings of his wife at a very low figure—as something that may at times enable them to indulge in an extra luxury, but not as contributing to the necessary household expenses. He ought to assume that his children, before their tenth year, will earn nothing, and that for some years after their earnings will amount to a mere trifle. The sources of his income being thus ascertained, he must next look his expenses fairly in the face. It is a duty he owes to himself and society to aim at procuring for himself a sufficient allowance of nourishing food, comfortable clothing, the means of preserving cleanliness, so requisite to health, and weather-tight, well-ventilated lodgings, with the necessary fuel. The same comforts which he aims at for himself, he becomes bound to procure for her whose time after their union ought to be mainly directed to caring for the comforts of him and his children. And for those children he is bound, by every natural feeling, to provide while they are unable to provide for themselves, in such a manner that they shall start upon life with hale constitutions and a fair elementary education. From his knowledge of his own expenses as a bachelor, and from what he can learn of the expenses of his married neighbours, he can form a tolerably near estimate of what marriage is likely to cost him. He must take it for granted that unforeseen accidents are more likely to occur in a family consisting of two, three, or four, than in a family consisting of one; and on this account ought not to venture on the married state unless he or his intended has some little stock of savings laid up in the event of contingencies. This being provided for, he must next take into account whether his earnings can cover the certain steady outlay of a family, and deposit a trifle at intervals in the savings' bank; and whether there is a fair prospect of their continuing to increase, and at least not to fall off. If every prospect is favourable, he may take the step; if not, he incurs the almost certain danger of reducing himself and his family to a state of destitution—of increasing by his rash act the number of sufferers in society—of adding to the number of that class which is at once miserable in itself and the cause of misery to others.

When we ask all who have not a reasonable prospect of being able to rear and instruct a healthy family to abstain from marriage, we only ask of them to consult their own happiness; the benefit of their abstinence will be reaped by society at large as well as themselves; the bad effects of their rashness will be felt by society as well as themselves, but the deepest, bitterest dregs of the harsh draught will fall to be drained by them. We only ask them to submit to a necessity which it is in vain to struggle against. If they ask why they are to deny themselves a gratification which they see others indulge in, the answer is, for the same reason that they forego many other pleasures they may wish for, but cannot earn by honest industry. Marriage is a fruitful source of happiness when judiciously set about; but, like all other goods of this life, it must be earned, and those who are not in a condition to earn it (whether for want of employment or want of ability), ought in conscience to forego it. To rush blindly upon the cost of marriage, without forethought, encouraging their rashness by such groundless remarks as, 'When God sends mouths he sends meat,' is not even to snatch a pleasure they have not had it in their power to earn, for such inconsiderate matches have more of a curse in

them than of a blessing. A bachelor state may be less happy than a good marriage, but it is better than a rash one, which precipitates all parties into destitution.

It is the more necessary to impress the importance of the lesson, 'Learn to abstain,' because it is the most difficult to practise, on account of the strength of the impulse to be overcome, and the weakness of those subjected to it, from its reaching its intensest power at an age when the judgment is yet immatured and experience empty; and also because rash marriages are the great promoters of a destitute, and consequently a demoralised, unhealthy, and miserable population; and because the man who has taught himself, by struggling against inclination, to make his instincts bend to his reason in this matter, has strengthened himself to resist almost any other temptation. It is men (and women too) who know how to earn and how to practise self-denial—who know what it is to appreciate pleasures, but are able to reconcile themselves to abstinence—in whom inclination and will are under the control of judgment and reflection—who constitute the sound and useful portion of society. In proportion as this class preponderates, will it be possible to keep the healthiness and morality of the community at a high average.

## DEATHS.

A human being born with a sound constitution is calculated to live seventy years or upwards, under favourable circumstances; but, as we well know, all of us are surrounded more or less by circumstances unfavourable to life, by which, practically, our term of years is liable to be greatly shortened. Existence, as to duration, is proverbially the most uncertain of all things; and this because, from ignorance, incautiousness, and accidents, life is constantly coming into collision with the conditions calculated to destroy it. The conditions unfavourable to life come into operation, we have seen, before the human being has seen the light. They continue in operation throughout the whole of its appointed period; so that, out of any large number born, a certain proportion die in the first year, a certain proportion in the second, the third, and so on, until all are gone—only a certain comparatively small number attaining the full age which nature promises to sound life maintained in favourable circumstances.

The conditions necessary for healthy and protracted existence are institutions of Almighty wisdom; they are briefly enumerated in the article PRESERVATION OF HEALTH (No. 45), to which we refer. They vary in different countries, according to climate, civilisation, and political arrangements; and, as necessarily follows, are different in the same country in different ages.

## Table of Mortality for England.

During the eighteen years from 1813 to 1830, there were registered as buried in England and Wales 3,938,496 persons, of whom 1,942,301 were females. The ages of all these persons were, as far as possible, ascertained and stated; so that it was possible by these means to ascertain the rate of mortality at the different ages, for that period, and in that country. The table consequently formed is given at the top of next page.

It appears from this table, as it has done from others constructed in other countries, that while the births of males to females is as about 21 to 20, the deaths are in an opposite relation; that is to say, female life in general is of longest duration.

## Mortality at Various Ages, and Expectation of Life.

The great mortality of the early periods of life is very remarkable. One-fifth of the whole of the children born in England and Wales, appear from the above table to die in their first year. (A Belgian table represents no less than a tenth of the entire mortality as taking place in the *first month of life*.) The disproportion between the deaths of males and females, appears also to be greatest under the fourth year; a fact which confirms the common remark as to its being more difficult to rear boys than girls, and which, it may further be observed, is in harmony with the disproportion of still births.

From a table of mortality, a calculation is easily made with regard to the probable duration of the life of any person. The calculation is made, with regard to any particular age, by adding up, in a table of mortality, all the deaths after that age, and dividing the sum by the numbers living at that age. The quotient is the *expectation of life* of a person of that age. A table of the expectation of life, for service in life-assurance and annuity business, is formed by doing this with regard to every age, and putting the whole in proper succession. We here present such a document, formed from the above mortality table, but only showing the expecta-

tion at every fifth year; joined to which is a similar table formed from the Million Tontine of 1695, and indicating very clearly the improvement of life in England during the last hundred years:—

Diseases.

Of the specific causes of mortality, it is difficult to procure anywhere a proper estimate, on account of the imperfection of most systems of registration, and particularly the want of precision and uniformity in naming various diseases. The system of registration now established in England is conducted upon enlightened principles, and appears to have hitherto been managed with great regard to correctness. It has enabled its able director, Mr Farr, to draw up very minute and comparatively satisfactory tables of the fatality of diseases in England and Wales for several recent years. The registered deaths of 1838 were 342,529, of which 175,044 were of males, and 167,485 of females. The causes of death were assigned in 330,559 instances; assuming that the other cases might be distributed proportionally among the assigned causes, a table was constructed, of which the following is a summary:—

Age.	Million Tontine of 1695.		Parish Registers, 1812-1830.	
	Expectn. Males.	Expectn. Females.	Expectn. Males.	Expectn. Females.

POPULAR STATISTICS.

The healthy occupations of the country make a difference in its favour in the general mortality; but this appears larger than it really is, in consequence of the flocking of the worn-out and miserable to large towns, and the occasional resort of sick persons thither for the sake of medical attendance, in the course of which life is in many instances cut short. In 1838, out of equal numbers in town and country, the deaths in the former appeared to be 101,019, and in the latter only 70,410. The average of life in the country would thus seem to be 50, and in the city 37; but if the above modifying causes are taken into account, the disproportion must be deemed considerably less. As might be expected, diseases are of different fatality in country and in town. Taking similar amounts of population in each, Mr Farr found that, for 1'00 in the counties, there were in the cities, 'by asthma, 3'80; erysipelas, 2'71; convulsions and teething, 2'57; cephalitis and hydrocephalus, 2'41; hydrophobia, 2'37; pneumonia, bronchitis, and pleurisy, 1'99; delirium tremens, 1'98; typhus, 1'88; small-pox, 1'73; heart disease, 1'73; childbirth, 1'63; syphilis, 1'59; rheumatism, 1'58; gout, 1'55; hernia, 1'48; purpura, 1'46; sudden deaths, 1'45; liver disease, 1'45; hepatitis, 1'35; tetanus, 1'32. The excess of mortality in cities was of less amount in the following cases:—By consumption, 1'24; croup, 1'23; violent deaths, 1'17; stone, 1'11; mortification, 1'10; malformations, 1'07; apoplexy, 1'07; hæmorrhage, 1'02.' Of some other diseases, the fatality was greatest in the counties. The 'mortality to 1'00 in the counties was, in the cities, by paralysis, '99; dropsy, '99; jaundice, '99; diabetes, '97; cancer, '92; hydrothorax, '88; hæmatemesis, '79; debility (frequently premature birth), '75; atrophy, '75; scrofula, '46.'

London is, upon the whole, healthy for a large city, the annual mortality being 1 in 42 of the population—a proportion very little above that of England and Wales (1 in 46). But the general healthiness of London is in some measure deceptive. It contains districts and kinds of population widely different; and the effects of wealth, spacious accommodations, and comparative cleanliness at the west end and in the suburbs, makes up in a summary for the opposite conditions of the eastern parts. This is rendered clear by the following statement:—

	Annual Deaths per cent.	Or
Whitechapel, . . . . .	3266	1 in 36
St George's, Southwark, . . . . .	3297	1 ... 30
Bermondsey, . . . . .	3123	1 ... 32
St Pancras, . . . . .	2698	1 ... 49
Camberwell, . . . . .	1925	1 ... 52
Hackney, . . . . .	1826	1 ... 54

It is to be observed that all these results rest, not upon the population as actually known, but as computed hypothetically from the census of 1831. Their accuracy of course cannot be entirely depended on, but they may be received as good approximations. The effect of crowding is shown by a table, exhibiting the mortality, and the number of square yards of space to each person in three groups of metropolitan districts.

	Square Yards to each Person.	Annual Morta- lity.	Mortality from Typhus alone.
1st group of ten districts, 25	3428	349	
2d ... .. 119	2786	181	
3d ... .. 180	2289	131	

Hence we perceive that typhus is nearly three times as fatal in the first or crowded group as in the third or open one.

Glasgow is believed to stand lowest amongst British cities in point of health, and for some years its unhealthiness seems to have been steadily on the increase. In 1831, the rate of mortality was 1 in 39 and a fraction; in 1831, it was 1 in 30 and a fraction; in 1838, 1 in 26 and a fraction. In 1821, the deaths of children under ten years of age in this city were 1 in 75; in 1839,

they were a little under 1 in 48. The extreme mortality of Glasgow is readily accounted for by the existence of a vast horde of miserable people in the meaner and closer parts of the city. Mr Symons, an English gentleman who had taken pains to make himself personally acquainted with the subject, states as follows:—'It is my firm belief that penury, dirt, misery, drunkenness, disease, and crime, culminate in Glasgow to a pitch unparalleled in Great Britain.' This class becomes a focus of typhus fever and other pestilential disorders, which emanate from it to the rest of the inhabitants, and generally prove very fatal. In 1839, the deaths from typhus fever alone reached 2180. It may be remarked that statistical science, which has been cultivated to an unusual degree in Glasgow, gives an unfavourable view of the city in a number of respects. In the five years previous to 1831, the average births in Glasgow were 1 to 29'47 of the population; the burials 1 to 30'91; and the marriages 1 to 105; the respective average numbers for entire England during the same period being 1 to 37, 1 to 54, and 1 to 129. It thus appears that there are in Glasgow more marriages, more births, and more deaths than in the country generally. In the parish of Montreux, where the births are 1 to 46 of the population, nineteen out of twenty complete the first year of life, and very nearly four-fifths of those baptised have been observed to live to receive the sacrament of communion.

A similar correspondence between many marriages, many births, and many deaths, is shown in the returns from Liverpool, as appears from the following passage in Dr W. C. Taylor's work, 'England in the Nineteenth Century:—'The site of Liverpool is low, and we regret that, upon examining the returns of the population for 1841, and comparing them with those of the births, marriages, and deaths, we should have found such a startling result—a result not so surprising to us as it would be had we not seen some of the older returns. In 1662, the baptisms were 30, and burials 30; in 1700, as above, the former 131, the burials 125; in 1800, the baptisms 3033, burials 3157. The births registered in 1839, when a close approximation to correctness in the returns took place, were 7128, deaths 7437; in 1840, with a population of 223,054, the returns showed 9990 deaths to 9925 births. We then went farther, and made calculations upon a basis every way favourable; for we applied to the Population Returns of 1841 the Registrar-General's return of births and deaths for 1840 in Liverpool, consequently we applied them to nearly the tenth part of a clear increase more than we ought, and the result, compared with the totality of England exclusively of Wales, made from a table in which the decimal surplus population was deducted from England alone, gives the following figures:—

	Births to Population.	Deaths to Population.	Marriages to Population.	Births to Mar- riage.
Population of all England reduced to June 30, 1840, 14,767,751, . . . . .	1 to 31'07	1 to 44'45	1 to 125'29	4'03
Liverpool, 223,054,	1 ... 22'47	1 ... 22'62	1 ... 60'6	2'6

'Here are startling anomalies,' remarks Dr Taylor; 'double the deaths and marriages, and little more than half the number of births [to a marriage], averaged in the totality of England.'

Effect of Seasons.

Seasons affect mortality very considerably. We have already adverted to the popular notion that a mild winter is the most fatal to life, and mentioned that it is the reverse of the fact. Severe weather in reality affects life to a much greater extent, particularly in some classes of ailments, than could be supposed likely. One table, prepared from the Belgian registers, shows a surprisingly gradual decline of mortality as the spring and summer advance, and then an equally gradual increase towards the middle of winter, the influence being rather more marked in country than in town:—

## CHAMBERS'S INFORMATION FOR THE PEOPLE.

Months—1815 to 1826.	Deaths.	
	Town.	Country.
January, . . . . .	69,892	116,129
February, . . . . .	56,267	114,738
March, . . . . .	84,277	114,244
April, . . . . .	81,818	107,264
May, . . . . .	48,911	93,714
June, . . . . .	46,607	84,464
July, . . . . .	45,212	77,555
August, . . . . .	47,033	78,692
September, . . . . .	80,191	85,131
October, . . . . .	61,649	89,814
November, . . . . .	52,908	89,525
December, . . . . .	55,631	98,705
Average, . . . . .	51,700	95,822

In 1838, the weather at the commencement of the year was more than usually cold, and in certain classes of diseases the mortality of that year in the metropolis for the different seasons was as follows:—

Causes of Death.	Winter.	Spring.	Summer.	Autumn.
Paralysis, . . . . .	234	181	135	187
Apoplexy, . . . . .	299	241	201	246
Asthma, . . . . .	760	325	97	331
Hydrothorax, . . . . .	90	73	43	79
Bronchitis, Pleurisy, } Pneumonia, }	1690	870	545	1154
Influenza, . . . . .	31	18	3	11
Diseases of the Heart, &c.	973	159	177	211
Diabetes, . . . . .	12	4	1	6
Dropsy, . . . . .	501	427	375	465
Mortification, . . . . .	84	50	85	66
Sudden Deaths, . . . . .	216	165	105	146
Old Age, . . . . .	1383	969	778	961

The disproportion, it will be observed, was greatest in diseases of the respiratory system, which, of course, was that most liable to be affected.

### Effects of Wealth and Civilisation.

The progress of wealth and civilisation takes a prominent place among the conditions either causing or accompanying a reduction of mortality.

The number of deaths that occurred in the city of London in 1697, was 21,000; a century later, in 1797, the number was only 17,000, notwithstanding the increase of the population. About the middle of last century, the annual mortality in the same city was as high as 1 in 20; in 1830, it was 1 in 41. Of course, in the metropolis of a great nation, an increase in the number of inhabitants is not necessarily a proof that the indigenous population is increasing; but the average of deaths being in London 1 for every 41 inhabitants in 1830, and the average of registered baptisms (everywhere in this country less than that of births, and most of all in London), being in the same year 1 in every 31, we know that, independent of the increase from immigration, the population of London has been steadily augmenting. The statistics of the city of Amsterdam present a remarkable contrast to this picture. In 1727, the annual average of mortality was 1 death for every 27 inhabitants; and the average for the twelve years preceding 1832 was the same. During these twelve years, too, the average of deaths in a year was 7336; the annual average of births only 7282. If during that period the population of Amsterdam did not positively decrease, it must have been kept up by immigration.

There is another point of difference in the career of these two cities for a century back. Whilst the wealth of London has been increasing almost in a geometrical ratio, the commerce of Amsterdam, and with it the opulence of the city, has been diminishing. Here, then, we have two striking examples of an increase in the mean value of life attendant upon augmented wealth, and, at the least, a stationary condition of that mean value attendant upon a diminution of commercial prosperity. The analogy is marked, and not surprising.

between the fortunes of communities and individuals: in both cases, opulence (that is, the comforts of which opulence gives command) has a tendency to improve the general health and prolong life. This, however, is taking but a superficial view of the question; to enable us to turn such knowledge to account, we must go more closely to work, and examine in what manner the beneficial change is produced. If we do this, there are facts established by the statistical inquiries which have of late years been made in Europe (although the science of statistics can scarcely be considered as far advanced beyond its mere infancy), which will show us that the increased wealth of a community is rather an attendant upon its increased health than a cause. They are both mutually causes and consequences—both the results of advancing civilisation, and both contributing to carry on that civilisation to a yet higher pitch. A recapitulation of some of the most striking circumstances either attendant upon, or productive of, the increasing health of a community, will be found fraught with useful practical lessons.

The ascertained facts regarding the rate of mortality in our own country, since the commencement of the reign of George III., invite to investigation. 'The annual number of burials,' says Mr Rickman, in the preface to the Population Returns of 1841, 'as collected in pursuance of the population acts, authorises a satisfactory inference of diminished mortality in England; the average number of burials not differing materially from the year 1780 to the year 1815; the first five years of that period, the last five years, and the whole period of thirty-six years, giving the same average result of 193,000 registered burials, the population having increased 3,300,000 in the meantime.' It appears from a subsequent part of the preface, that the annual mortality in 1780, as near as could be ascertained, was 1 in 34 or 35 of the population; that in 1820 it was 1 in 49. On the other hand, the same authority states—'The mortality of the inhabitants of England appears to have sunk to its minimum in the decade preceding the population abstract of 1821; and since that time it seems to have risen as fast as it descended after the year 1800. The census of 1841 gives one death annually for every 44.5 persons.' According to the Registrar-General's reports, the average mortality in England and Wales for the six years ending 1844 was 1 in 46—showing again a slight improvement. The extremes vary from 1 in 37 in Lancashire, to 1 in 55 in Surrey, Sussex, and North Wales.

In general terms, it may be remarked that the commencement of the diminished ratio of mortality is nearly contemporaneous with those inventions which contributed to give such an increased power to the productive industry of the nation. The Duke of Bridgewater and Brindley constructed the Worsley and Manchester Canal between 1758-60, and the Liverpool and Manchester Canal between 1762-67. In 1769, the connection between Boulton and Watt for bringing into play the patent obtained by the latter for improvements in the steam-engine was formed. In 1775, the partners obtained from parliament a further extension of the patent, which shows that they were then only beginning to reap the advantage of the improvements. Arkwright obtained the first patent for his spinning machinery in 1769, and his second patent in 1775. His first water-mill was erected in 1771; but five years elapsed before he began to derive any profit from it. The influence of these improvements was, from their commencement, of the most marked kind, and it ramified over the whole country.

By means of these inventions, conveniences and luxuries were brought within the reach of incomes which previously could not afford them; and the extraordinary cheapness and goodness of British manufactures, with such advantages, so increased the demand for them in foreign markets, that the manufacturers found the supply of labour insufficient. The national wealth was not only increased, it was diffused through all classes of society. Increased incomes, the spirit of

rivalry, prompted all classes, the labouring-class as well as others, to live more comfortably; better clothed, housed, and fed, men became liable to fewer diseases.

From the middle of the eighteenth century, a stimulus had been given to the popular intellect, and the English were becoming a reading nation. The great inventors were themselves chiefly members of the middle and humbler classes, and the earliest of the great manufacturers were so likewise. Sunday schools, book-clubs, and the diffusion of newspapers, were perhaps amongst the most serviceable means of enlightening the people of England during the reign of George III. At last came Joseph Lancaster and his cotemporaries with their cheap apparatus for the elementary education of the masses. When we find such circumstances accompanying the diminution of mortality in England, we cannot refrain from supposing them in some measure connected.

We deem it, then, tolerably clear that the great promoters of the health of individuals are—increased affluence, relieving the mind from despondency or harassing care, and furnishing the means of cherishing the body; and increased intelligence, teaching how to derive the most advantage from this affluence, and laying the foundation of habits of judicious self-control; and that the great promoter of the health of communities is the extension of these advantages to as many of the individuals or classes composing them as possible. The possession of affluence, and the intelligence requisite to acquire, retain, and use it aright, is the main distinction between what are called civilised and savage men. In the common practice of sinking the individual in the class—speaking of nations as resembling or contrasted with nations—we are apt to overlook the fact, that every civilised nation is not necessarily composed exclusively of civilised human beings. In every nation, even in our own, there are many who grow up, live, and die, unreflecting creatures of impulse, scrambling day after day to snatch a precarious livelihood—now gorged, more often starved—ignorant of responsibility to God or man—in short, as complete savages as are to be found among the woods of America or in the bush of New Holland. The detrimental influence of a numerous class of this kind being left in any society is not confined to itself. Its existence does not merely lower the average of virtue and comfort in a country by diminishing the ratio its sum bears to the total of the whole population; the contagion extends to the civilised or comfortable classes, who are, by proximity, brought into contact with it. From the squalid dens in which this class congregates, emanate contagious diseases that penetrate into the dwellings of the wealthy. Its numbers compose what an eminent statist has aptly called ‘the dangerous classes of large cities;’ the ranks of our thieves and housebreakers are perennially recruited from among them. They constitute, in times of domestic contention, the brute instruments of the wicked of the *civilised* class. They are a chronic disease in the social body; and a nation can be healthy only in proportion as they are diminished in number, or become humanised by a participation in the comforts of their more favoured brethren.

The advantages which society has derived from augmented wealth and extended education, may be distributed under three classes, according as they proceed from greater facility of procuring physical comforts, owing to their greater abundance, or from the greater power of contributing to their own enjoyment by regulating their moral conduct, which men derive from intellectual cultivation, or from the union of both these causes. We proceed to illustrate, by some brief statistical details, the mode of operation in each of these three classes:—

The advantages which the whole community derive from an increase of wealth, and its source, more efficient application of industry to the natural wealth of the country, are of two kinds—those in which all participate, even those who do not exert themselves; and those of which individuals acquire a share by their per-

sonal exertions. Of the first kind are the benefits resulting from drainage in town and country. The stimulus given by the inventions adverted to at the outset has extended to agriculture; and the efforts which have been made to render land which was not productive, or productive of little, more fertile, have indirectly contributed to promote the public health. The draining of the fen counties on the east coast of England, has banished a class of diseases which were most destructive in these districts. The fevers of Essex used to be inferior in virulence, but scarcely inferior in frequency, to those of the Pontine marshes. With the drainage of the marshes of that county these fevers have disappeared. ‘The intermittents,’ says Mr Rickman, ‘which, heretofore, under the name of ague, infested the country very extensively (especially the fen districts), are no longer spoken of.’ In the time of Richardson the novelist, as we learn from his published correspondence, the scourge visited periodically even those families which were in easy circumstances. The change for the better is of course most manifest in the positively unhealthy districts, but it is experienced in the diminution of chronic rheumatisms, wherever surface drainage and underground drainage have extended. The exertions of the more wealthy classes in large towns, to promote by sewers and other aids of public cleanliness their own health and comfort, has in like manner indirectly tended to promote the health and comfort of all classes. There are nooks and corners in London, inhabited exclusively by the poor, which are still badly enough off in this respect; but we do not, even in them, find ‘the kennels running blood two days in every week,’ as Dr Johnson has left on record was the case in Southwark in his day; nor do we find ‘pigs bred and fed in the houses or back-sides of paved streets,’ routed out in droves by the constables in the fashionable purlieus of St George’s, Hanover Square, as was the case in 1761.

The advantages which each individual must acquire for himself by his own exertions are, generally speaking, superior household accommodation, clothing, and food. Previous to the impetus given to national industry in the early part of the reign of George III., the following are the rates of wages which the labouring-classes of England had in their power to earn per week:—*Men*—In the iron works at Rotherham, 10s.; in the cutlery and plating trades at Sheffield, 13s. 6d.; in the cloth manufactures at Wakefield, 10s.; the colliers in that neighbourhood, 11s.; in the manufacture of cloth at Leeds, 8s. 3d.; at the alum works at Ayton, in Cheshire, 7s. 6d.; in the lead-mines at Fremington, in Yorkshire, 7s. 6d.; the colliers of Newcastle, 15s. 6d.; in the manufacture of cottons and checks at Carlisle, 9s.; in the manufacture of stockings, cottons, and linsley-woolseys, in the tanneries at Kendal, 9s. 5d.; in the making of pins and shoes at Warrington, 8s. 7d.; in the manufacture of fustians, checks, hats, and small-wares at Manchester, 7s. 1d.; in the potteries at Burslem, in Staffordshire, 9s. 6d.; in the manufacture of piece-goods at Witney, in Oxfordshire, 11s.; making carpets at Wilton, in Wiltshire, 11s.; pins in Gloucestershire, 11s.; says and burying-crape at Sudbury, 7s. 6d.; says and calimancoes in Suffolk, 5s. 9d.; flannels and linseys at Salisbury, 8s. *Women*—In the lace manufacture at Bedford, 4s. 6d.; in the cloth manufacture at Leeds, 3s.; in the lead-mines at Fremington, 6s.; in the Kendal manufactories, 3s. 3d.; in making pins and shoes at Warrington, 4s. 6d.; making shoes and hats at Newcastle, 4s. 6d. *Children*—In the porcelain and glove manufactures at Worcester, 2s. 6d.; of shoes and hats at Newcastle, 1s.; boys in the potteries at Rotherham, 3s.; boys and girls in the Fremington lead-mines, 3s. 3d.; children at Kendal, 2s.; children at Manchester, 3s. 5d. The medium rate of the wages of manufacturing labour was—in the east of England, 6s. 6d.; in the south, 9s. 4d.; in the west, 11s. The medium rate of agricultural wages was 8s. in the eastern counties; 6s. in the southern; and 5s. 10d. in the western districts. These rates were ascertained by Arthur Young

in his tours of 1768 and 1770. Young estimates the population of England and Wales, in 1770, at 8,500,000: of these he gives 2,800,000 as the number engaged in agriculture—the landlords, with their families and dependants, amounting to 800,000; and the number engaged in manufactures, 3,000,000. This, on a rude estimate, would give the numbers of the population dependent upon the wages of labour for subsistence, of that time, at less than 4,000,000. He estimates the non-industrious poor at 500,000.

The information given by Mr Jellinger Symons in his 'Arts and Artisans at Home and Abroad,' published in 1839, enables us to contrast with Young's statements the capability of earning possessed by the labouring-classes of England in our own day:—*Men*—In Manchester, a spinner can earn from 20s. to 25s. a week; a man in the card-room, 14s. 6d. to 17s.; a weaver by power, from 13s. to 16s.; by hand, from 7s. to 13s.; dressers earn from 28s. to 30s.; and mechanics from 24s. to 26s. The wages at Sheffield vary from 25s. to 35s., and often amount to 40s., for workmen in the skilled departments; in the iron-works of the Birmingham district, wages average from 20s. to 30s. for the common labourers; in the Leeds flax-mills, men earn from 17s. to 19s. a week; in the Gloucestershire cloth-factories, from 12s. to 14s. In other trades, the average wages per week throughout England are—iron-founders, 28s. to 30s.; machine-makers, 26s. to 30s.; sawyers, 24s. to 28s.; carpenters, 20s. to 25s.; stone-masons, 18s. to 22s.; bricklayers, 17s. to 20s.; spadesmen, 10s. to 15s.; porters, 14s. to 16s.; colliers, 3s. 6d. a day; stocking weavers in Leicester, 8s. 3d. per week. *Women* earn per week, at Manchester, as spinners, 10s. to 15s.; in the card-room, 9s. to 9s. 6d.; weavers by power, 8s. to 12s.; by hand, 6s. to 12s.; in the Leeds flax-mills, 5s. 6d. to 6s. 6d.; in the Gloucestershire cloth-factories, 4s. to 5s. Children can earn in the Manchester factories from 1s. 6d. (scavengers) to 7s. a week; in the Leeds flax-mills (when nine or ten years old), 3s. 6d. to 4s. 'Agricultural wages,' says Mr Symons, 'in England vary so little, and are so well known, that I need hardly do more than state, that in the Coteswold districts, for instance, a shepherd receives 10s. weekly; a carter, the same; day-labourers, 8s. in summer, and 6s. in winter; in addition to which, they earn 3 guineas at harvest time, which will pay their rent. Women receive 6d. a day in winter, and 8d. in summer, and 1s. in time of hay and harvest. Perhaps these are the lowest wages paid in any district in England. From 8s. 6d. to 10s. 6d. will be throughout the average wages of the great bulk of adult male agricultural labourers of England. These rates of wages are taken at a period when the remuneration of labour is retrograding in a marked manner. Even under this state of affairs, however, they show that the increase of national wealth has at least given individuals of the labouring-class the command of a greater money income.

The labourer's power of commanding the comforts of life can only be partially known from a statement of his earnings; attention must be paid to what these earnings can purchase. The principal expenditure of the labourer, as already stated, is in house-rent, clothing, and articles of domestic consumption. By the improvements of machinery, all classes are enabled to procure better clothing at a lower price than they formerly paid for an inferior article. The extent to which this change has been carried, may be inferred from one or two facts regarding our manufactures. In 1787, when the mule-jenny first came into common use in Bolton, Paisley, and Glasgow, the manufacturers paid for their fine yarn at the rate of 20 guineas per lb.; the same quality of yarn has of late been sold at from 13s. to 15s. a lb. The cotton twist, which sold in 1786 for £1, 18s. per lb., is now sold for 3s. The process of reduction in the price of manufactured goods is still going on, and in the linen as well as in the cotton trade. Canvas, No. 27, an article, the quality and dimensions of which do not vary, which sold in 1814 at 30s. a piece, had fallen in 1833 to 18s. In the woollen manufac-

tures, a great reduction of price compared with quality has also taken place. The consequence is apparent in the style of dress adopted by the working-classes of Great Britain, so different from what prevails on the continent, and did formerly prevail here. As to houses, every person who has attained to middle age must have remarked the improvement in many districts of the accommodation for the labouring-classes in this respect; and yet the money rental seems to have remained nearly stationary. Young states the house-rent of the working man to have been in his time—at Leeds, £2; Wakefield, £2, 5s.; Newcastle, £2, 12s. 6d.; Hatfield, £2, 15s.; North Mines in Middlesex, £3, 10s.; Kensington as high as £5. In 1839, the average rental of a labourer's cottage in the country near Penzance was about £3; in the town, £5; in the county of Rutland, £1, £1, 10s., and £2. In Suffolk, in 1838, the house-rent of 539 labourers' families averaged £3, 11s. per family; in Northumberland, the average rent of a labourer's cottage was estimated at £2, 10s. Even the price of provisions, which is generally supposed to have been so much lower in former times, has not increased, if it has increased, so much as is supposed. The average prices of butcher meat, beer, cheese, milk, and butter, throughout the kingdom, do not materially differ now from what they were in 1760; bread is somewhat dearer, but improved in quality, and potatoes in ordinary years are much cheaper. Tea, coffee, sugar, and pepper, have been greatly reduced in price; and now, instead of scarcely ever appearing in the weekly bills of the labourer, are standing articles of his expenditure.\*

This improvement in the quality of the accommodations procurable by a moderate income must always be kept in view, when comparing what a man can earn now with what he could earn formerly.

It would, however, convey a false impression of the amount of social advantage at any time derived in Great Britain from the great increase in the productive powers of industry, were we to leave unnoticed the large and increasing class which has never yet been reached by these benefits. Even in the most busy marts of industry, numbers are to be found, and these not always entirely unable or unwilling to work, who are in a state bordering upon destitution. We have a remarkable example of this class in the city of Limerick, where a large district is in a manner given up to them. In England, it is to be observed, the mean value of life among the more comfortable portion of the working-classes is now as high as that of the middle classes in last century: this appears from comparing the experience of the Amicable Insurance Office, established in 1706 for the benefit of the middle classes, with the table of mortality collected by the Society for the Diffusion of Useful Knowledge, which embraces the history, as to mortality, of 24,323 years of life among the labouring-classes from all parts of England, from 1823 to 1828. In Limerick, on the contrary, while the deaths in the three tontine societies there founded in 1807, 1811, and 1814, and with lives injudiciously selected, show respectively one death annually in 108, 61, and 182 persons, the annual mortality among the poor is 1 in 19. This is not all. 'The frightful excess of epidemic and endemic diseases among the poor of Limerick may be gathered from the following fact, that while the per-centage proportion of this class to the whole number of deaths in England and Wales in 1838 was under 20 (19·8); in the metropolis and Leeds, 26·1 and 26 respectively; in Manchester, 23·2; in Birmingham, 20; and in Liverpool, 19·8; it is in Limerick not less than 40, or nearly five times as great as the proportion of deaths from diseases of the respiratory system, to which, among a healthy population, it ought to be nearly equal.\*' Among the families of

\* 'Wherever the absolute mortality is low, the number of deaths in the epidemic class is less than the number in the pulmonary class; and on the contrary, wherever the deaths in the first class exceed or equal those, it may be affirmed that the absolute mortality is high.'—*First Report of Registrar-General.*

## POPULAR STATISTICS.

this class who come under the notice of Dr Griffin—' Out of 66 who had more than 10 children born alive, 18, or one-fifth, had lost 11 or more of those children; and the aggregate mortality of those families was 159, or 12 each, which, if distributed among the same number of families who had the greatest number of children born alive, amounts to 79 per cent., and was probably higher.' He adds—' It has been remarked that production is often most rapid among a population in extreme wretchedness; and I strongly suspect that this is a consequence of the high mortality which occurs in such circumstances. It is the character of any influence which tends greatly to depress the powers of life, that it always bears heaviest on the tenderness of infancy and the feebleness of age. Now, as I find that the poor nurse their own children, there is generally an interval of about two years between the birth of one child and that of the next; but if a child dies early on the breast, this interval will be much shorter; and if this occurs often, there will be a certain number born, as it were, for the purpose of dying.'

### Effects of Increased Wealth and Knowledge in Combination.

Some results from the combined influence of increased wealth and knowledge may now be adverted to. It is to be observed that the rich could at all times command many comforts favourable to life; but it is only when knowledge suggests a right employment of the means afforded by opulence, and opulence on the other hand exists to avail itself of the aid of knowledge, that the full benefit of the conditions we have been reviewing can be said to be realised. The following illustration may make our meaning more clear:—

It is commonly believed that there is more danger to life from lithotomy than from amputation; but statistical inquiry shows that death more frequently follows the latter than the former operation. The results of 640 cases of amputation of legs and arms, in hospitals and private practice, in France, Germany, United States, and Great Britain, were in 150 cases fatal—a ratio of 23½ per cent.\* It is to be kept in view, however, that the mortality in cases of amputation very frequently arises from the injury or disease on account of which the operation is resorted to; whereas the mortality from lithotomy is almost invariably the direct defect of the operation alone—the surgeon having it in his power, in the latter case, to choose a time when the patient is in the best condition to endure the suffering, which he can rarely do in cases of amputation. When we reflect upon the intimate acquaintance with the human frame, and the confidence in his own skill, which the surgeon can only acquire by dexterity, the result of much practice and the traditional experiments of his predecessors, we are able to form some idea of the importance of knowledge in alleviating the miseries of humanity. And when we add the consideration of the cost of instruments, medicines, and the time and trouble requisite to constitute a good surgeon, we are able to form some idea of the extent to which stored-up capital is necessary to men having been able (in the first instances at least) to give and receive this alleviation.

Another example of the benefit of the co-operation of increased national wealth with increased knowledge, is the diminished risk of life in cases of child-birth. It may appear that we are wandering from the consideration of wealth, seeing that the examples we are about to subjoin are selected from the returns of lying-in hospitals—the only trustworthy statistics on this point. But it must be kept in mind, that a nation must be wealthy before it can support such institutions; that the improvement so marked in the case of the poor, must be *a fortiori* greater in those who can afford continued watching and the best assistance; and that the affluent classes must have enjoyed the benefit before it could be extended to the poor. The process by

which a share in this and other privileges of the rich has been extended to the poor, is a question for after investigation. With this explanation, we submit the following quotation from M. Quetelet's 'Treatise on Man,' to show the mortality of women in child-birth, and their children:—

'According to Willan, the mortality in the great lying-in hospital in London, into which about 5000 women were annually admitted, was—

	Of mothers.	Of children.
From 1749 to 1758, . . . . .	1 in 43	1 in 15
... 1759 ... 1768, . . . . .	1 ... 50	1 ... 30
... 1769 ... 1778, . . . . .	1 ... 55	1 ... 43
... 1779 ... 1788, . . . . .	1 ... 60	1 ... 44
... 1789 ... 1798, . . . . .	1 ... 268	1 ... 77

According to Casper, the mortality of confined women at Berlin has been—from 1758 to 1763, 1 in 95; from 1764 to 1774, 1 in 82; from 1785 to 1794, 1 in 141; and from 1819 to 1822, 1 in 152.'

The same author supplies us with an estimate of the sanatory influence of vaccination:—In most civilised countries there are enactments on vaccination, of greater or less severity, which are enforced with proportionate rigour. According to Casper and several other savans who have written on the ravages caused by the small-pox, it would appear that formerly generations were decimated by this scourge—that is to say, one-tenth of the human race died from it. Duvillard has found—1st, That in the natural state, of 100 individuals of 30 years of age, scarcely four individuals have escaped an attack of small-pox; 2d, That two-thirds of all infants are attacked by it sooner or later; 3d, That small-pox, in the early years after birth, destroys, on an average, one out of every three who are affected with it; 4th, And one dies out of every seven or eight affected, at whatever age it may be. Such was the state of things before the discovery of vaccination; it has since been much ameliorated. However, in 1817, 745 persons died in Paris of small-pox; in 1818, 993; and in 1822, the number was as many as 1084. Also, at St Petersburg, in 1821, 408 deaths took place from it; and at Vienna, 238 in 1822; whilst in London, in that year, there were 712. Prussia has been much better dealt with than other countries: during the two years 1820 and 1821, taken together, only 1 in 7204 persons died; whilst France lost 1 in 4218 the last two years. The following are the data of Berlin for almost half a century:—From 1782 to 1791 inclusive, 4453 deaths; from 1792 to 1801, 4999 deaths; from 1802 to 1811, 2955; from 1812 to 1822, 555. The number of deaths for the last period, which is extremely small in comparison with the preceding years, would be still less if the deaths for 1814 and 1815 were subtracted, during which time vaccination was neglected. Indeed these two years had 411 deaths from it; so that during the others there were only 114. But we should fall into a serious error, as M. Villermé has said, if we counted as gain to the population all those individuals who had been vaccinated, and not carried off by the small-pox. "An epidemic, or any other malady against which we endeavour to secure ourselves," says M. Villermé, "indeed suppresses one cause of death; but from that circumstance the probability of dying from some other disease becomes greater. In other words, by closing one of the gates of death, we open the others wider, so that more persons pass through these latter; which is not saying that mortality should be equally rapid. Consequently, vaccination, and every preservative against epidemic disease, or any disease whatever, does not increase the population of old Europe directly, but, what is still better, it alleviates the lot of those whom it snatches from the chance of the small-pox, it diminishes the number of the blind, it preserves the native beauty of the person, and increases the average duration of life."

This will scarcely be called an exaggerated estimate of the advantages resulting from the discovery of vaccination. In the three examples which have been adduced, the reader may see how far knowledge and afflu-

\* The recent application of anæsthetic agents in surgical operations is expected to diminish in a notable proportion the ratio of fatal to successful cases.

ence combined have served as preservatives against tangible dangers. But in so far as the affluent classes are concerned, this is but a small portion of the benefits they have conferred. The habits generated in these classes by the advancement of knowledge, at a time of increased diffusion of knowledge, have been favourable to a general healthy condition of the individual system, alike calculated to ward off the attacks of disease and to baffle them when they are incurred. Any person whose memory can carry him back for forty years, and who has had opportunities of observing, may remember the deficient ventilation, the small rooms, and the number of inmates in each room, which characterised even the houses of the landed gentry. In towns the evil was still greater. But it would require to carry the retrospect still farther back—to the time when Rousseau in France, and Davy and Edgeworth in England, commenced their crusades against unhealthy absurdities in the dress and manner of living of the wealthier classes—to imagine the whole amount of the improvement which has been effected in this respect. The improved taste of the wealthier classes has contributed to improve their morals; and, in return, the better regulation of their conduct has tended to improve their general health. The practice of deep drinking, which universally prevailed, has almost ceased to exist among the affluent classes. Literary and scientific pursuits, if they do not always guard against low debauchery, save many from it, and enable still more to recover, after yielding for a time to temptation.

An interesting paper, published by M. Benoiston de Chateaufort, entitled 'On the Duration of Life in the Rich and in the Poor,' corroborates these views. The author has made, on the one hand, an abstract of the deaths of 1600 persons of the highest rank, among whom are 157 sovereigns and princes; on the other hand, he has taken from the civil registers of Paris, the deaths of 2000 persons in the 12th arrondissement, which contains a population of workmen of all kinds—ragmen, sweepers, delvers, day-labourers, &c.—a class subjected to pain, anxiety, and hard labour, who live in want, and die in hospitals. Out of these materials he has constructed a table showing the per-centage of mortality among the two classes at different ages, and has added a column indicating the per-centage among the middle or easy classes. He found that, between 25 and 30, the deaths per cent. were—among the rich, 0; among the common class, 1.41; among the poor, 2.22: from 50 to 55—among the rich, 1.81; among the common class, 2.68; among the poor, 2.58: from 75 to 80—among the rich, 3.09; among the common class, 10.32; among the poor, 14.59. At this last age the column showing the deaths among the poor stops for want of materials—they had all died off; the column showing the deaths of the common class extends to the age of 90; that of the rich to 95. The same conclusion is indicated by contrasting the annual mortality shown by the annual average of deaths among the English middle classes who have insured their lives with the Equitable Society, and the annual average among the negro slaves. Among the former, it was only 1 in 81.5 from 1800 to 1820; whereas it has been calculated that one negro slave dies annually out of 5 or 6.

Some facts would almost seem to show, that the education enjoyed by the more affluent classes—the cultivation their minds received, partly from direct tuition, partly from their social circumstances—gave the mind an increased power of vitality. An officer of high rank in the service of a German state made this remark to the writer, when speaking of the disastrous retreat from Moscow, in which he had taken a part. The officers, he said, uniformly stood out longer than the privates, although the previous habits of both parties had led him to expect the reverse. Literary men, and artists who have attained to anything like a competence, are also a long-lived generation. The remark has been often made, of the greater facility with which young men, belonging to the class vaguely called 'gentlemen,' generally attain to superior adroitness in athletic ex-

ercises. Whenever a party of Etonians are pitted at cricket or running against a party of lads of a lower class, the difference is at once perceptible. Again, the facility with which the young men educated at Oxford and Cambridge—unapt though the system of education pursued in these two great seminaries be to prepare them for the real business of life—work their way into the routine of legal or diplomatic business, is well known. There is something in the strengthening influence of good and delicate feeding, clothing, and lodging, combined with exercise of the physical and mental faculties, sufficient to strengthen, not to exhaust, persevered in for generations, that ennobles the race of the human animal, just as careful grooming and crossing the breed judiciously, ennobles the horse. What is here spoken of, is not the power of such a process to confer genius, or true nobility of disposition; but to bring out in perfection all the average commonplace qualities of the human being. In any country, a superiority of this kind is discernible in the dominant caste; and as mere human animals, there is no country in the world that can produce a race equal to the young gentry of England.

#### Limits to the Effects of Wealth.

The limits to this favourable condition of the affluent classes in England, are to be sought partly in deficient knowledge and deficient habits of self-control; partly in a redundancy of numbers compared with property, which affects them in common with all other classes, though not exactly to the same extent. The deficiency of knowledge may be detected in several noxious practices still persevered in, such as tight-lacing on the part of the fair sex. The want of proper habits of self-control is a more deeply-rooted evil, inasmuch as it has its root in a physical fact too much overlooked by reasoners upon morals. When named, it will be found to be a very commonplace fact: it is, that every successive generation begins the world with as little experience as that which preceded it. Every one of us starts from as mere a state of ignorant barbarism as the child of the savage. We are forewarned of much by the instruction of those who have been taught by their own experience, or the experience of those who went before them; but there is much of which it seems impossible to forewarn us. The passions are fully developed before the reflecting powers; and every individual seems destined to experience a period of his existence in which imagination and passion are strongly and thrillingly awakened, while the guiding power of reason is yet dormant. This is the most dangerous, as it is perhaps the most pleasant, period of life; and it is one which is most dangerous with regard to that very class which is so highly favoured in other respects. Penury, or the necessity of daily labour, may restrain the less affluent classes at this period of life; but the younger branches of the affluent class have no such substitute for the control of reason; and in proportion as their general healthiness is higher, so their passions are developed, it may be, with greater intensity. It is at this period that many of the more favoured class make shipwreck of their health, incurring diseases which cling to them through life, if they do not bring it to a premature close.

The influence of economical circumstances upon the affluent classes, in regard to their moral and physical welfare, is quite as striking as their influence on the less fortunate classes, though somewhat different in kind. The anxiety occasioned to the upper classes by the prospect or actual pressure of pecuniary embarrassment, is of a much more harassing and exhausting kind than what is suffered by the poor. Pride, and all the other secondary feelings, with ranging imagination, add to their torments; and their occupations generally demanding a steady exercise of the faculties of combination and investigation, and keeping their minds continually on the stretch even in the time of prosperity—this addition renders their burthen more than they can bear, and the whole man breaks down

POPULAR STATISTICS.

beneath the weight. Excessive mental exertion, even under the most favourable circumstances, is known to be productive of fatal effects. Even children of affluent and fortunate parents have been sacrificed to the vanity which was gratified by their displays of precocious talent. The cupidity which grows upon men struggling to maintain their place in society, increases this evil by forcing on the acquirements of children, in the hope of seeing them able, at a comparatively early age, to provide for themselves. Caspar of Berlin published in 1834 a tabular statement of his observations on the sanitary tendency of various occupations, which serves to throw some light on this intricate question:—

Of 100 Theologians, there have attained the age of 70 and upwards, . . . . .	43
Agriculturists and Foresters, . . . . .	40
Superintendents, . . . . .	35
Commercial and Industrious Men, . . . . .	35
Military Men, . . . . .	33
Subalterns, . . . . .	32
Advocates, . . . . .	29
Artists, . . . . .	28
Teachers, Professors, . . . . .	27
Physicians, . . . . .	24

That physicians should stand lowest in this scale of vitality, is not, considering their exposure to contagion, to be wondered at; and the high grade of theologians is equally intelligible, from their certain though moderate income, and the equanimity favoured by their pursuits. It is, however, startling at first view to find the average duration of life among commercial men so little elevated above that of military men, in a table constructed in a country where war had raged at no remote period. The last fact seems to establish that the agitation of mind produced by mercantile uncertainties and difficulties is scarcely a less destructive agent than the sword.

There is perhaps a point in the development of national wealth and civilisation at which mortality shows a tendency to increase. Such an idea is naturally awakened when we learn that the mortality of England is now slightly greater than it was some years ago. The proportion of deaths to persons in the decade 1821-31, was 1 to 49; that of the decade 1831-41, according to the population returns, 1 to 44·5; and that of the six years ending 1844, 1 to 46.

EDUCATION.

The statistics of education have an obvious value in their connection with many questions regarding the civilisation of countries.

It is clear, however, that the state and amount of education in a country is a highly complex question; for, first, there may be much education of a poor and inadequate kind; and second, there may be conditions favourable to education in some countries, and not in others—as, for instance, the natural character of the people, the tendency of the political and social institutions, and the direction which the energy of the people chiefly takes, as towards war, commerce, or art. The numbers at school are also liable to be affected by the ratio of the increase of population; for where there is a rapid increase of people, there is always a greater than usual proportion of the young.

Prussia, where the most perfect of all national systems of education exists, as far as organisation is concerned, contained, according to a census taken some years ago, 12,726,823 inhabitants, of whom 4,767,072 were under fifteen years of age. It is reckoned that, out of 100 children from one day to fourteen years of age complete, there are 43 of full seven and upwards—a legal age for attendance at school in Prussia. This would give 2,043,030 children in Prussia liable by law to attend school. It was found, in point of fact, that 2,021,421 did attend, being only a shortcoming of 21,609, a small enough allowance for contingencies. Thus if we were to take Prussia as a criterion for old states, where the population does not advance rapidly, and consider the years between 7 and 15 as those pro-

per for school attendance, we should conclude that about one-sixth of the whole population of such a country should be at school.

Most of the German states make an approach to the organisation of the Prussian system; and we find that in Austria there was, a few years ago, one school for every 275 families. But the object of the governments in supporting education in Prussia and Germany generally, is said to be of a narrow kind—a species of drill, for the purpose of conferring the accomplishments of reading, writing, and arithmetic, and to train the young to a subserviency to the government itself.

Education was in a low state in France till the general peace of 1815, since which time it has become a government object, and made a rapid advance. The elementary schools instructed 737,369 pupils in 1815; in 1828, this number was raised to 1,500,000; being one-twentieth of the population. It is calculated, however, that more than one-fourth of the people of France are still unable to read or write.

In England and Wales, in 1818, there were 4167 endowed schools, 14,282 unendowed schools, and 5162 Sunday schools, educating in all 644,000 children, or one-sixteenth of the population. Of 11,000 parishes, 3500, or nearly a third, had no school whatever. Since then the number of both schools and scholars has been greatly increased. In 1838 the following returns were made to parliament:—

Attending Infant Schools, . . . . .	89,005
"    Daily Schools, . . . . .	1,276,947
Total, . . . . .	1,365,952
Attending Sunday Schools (supposed to be an exaggerated statement), . . . . .	1,546,800

Under the annually increasing grants for educational purposes, probably from a tenth to an eighth of the people of England and Wales are now receiving school instruction. Nevertheless there are still from 800,000 to 1,000,000 of young persons unprovided with the means of elementary tuition.

The registration of marriages, by which the parties are required to sign their names on being united, has supplied within the last few years a means of testing the proportion of those ignorant of writing throughout England and Wales. Of the 121,083 couples married during the year ending June 30, 1839, there were 40,587 men, and 58,959 women, who, being unable to write their names, were obliged to sign by marks. The proportion of men unable to write was thus 33, of women 49 per cent.; medium, 41. The number unable to write was least in the metropolis, and next to it in the northern counties; and greatest in Lancashire, Bedfordshire, Monmouthshire, and Wales. The trustworthiness of this test was confirmed by the registration of the ensuing year, when amongst the 124,330 married couples, 41,812 men, and 62,523 women, were found to sign with marks; and the proportion in the various districts was also nearly the same. It is to be remarked, that a large portion of the married couples recorded in these years must have consisted of persons who passed their educational years in times when the means of instruction were much less extended than they now are. A few years hence, the proportion of both men and women attesting the marriage-register with 'marks' will probably be much diminished.

Scotland, unlike England, possesses a national system of education, there being a legally-endowed school in every parish, under the care of the clergy. Returns to parliament in 1834 gave the following view of education in Scotland:—

	Schools.	Pupils.
Parochial, . . . . .	1047	68,293
Private, . . . . .	3995	154,160
Total, . . . . .	5042	222,453

The whole emoluments of the teachers of the parochial schools was £55,339, being at an average an income of 557

£45, 11s. 9d. to each. The aggregate sum was composed of—endowments, £29,642; fees, £20,717; other emoluments, £4979. Taking 68,293 as the number of pupils in the parochial schools (it was, however, the greatest attendance), each costs the public 15s. 7d. per annum. In the same year, the Sabbath School Union for Scotland taught 68,326 children.

The proportion of children taught *out of the parochial system* was unexpectedly great. It was greatest in certain counties, as follows:—

	Parochial Schools.	Private Schools.
Edinburghshire, . . .	82	460
Aberdeenshire, . . .	98	347
Lanarkshire, . . .	72	322

—and there was no county, except Peebles, where the parochial schools were the most numerous. Only one-fifth of the teachers and one-fourth of the scholars were under the parochial system. It is also to be remarked, that some of the schools returned as parochial were merely under the care and patronage of parochial clergymen, by whom they had been established. The returns were considered as not quite complete, and the number attending school in 1834 was *computed* as being more probably 523,154, the proportions in the two different classes of schools being nearly the same.

Notwithstanding the political agitations and poverty which have long depressed Ireland in many respects below the level of the sister kingdoms, it has certainly for many years been above at least England with respect to the elementary instruction of its people. The ability to read and write is observably much more diffused in Ireland than in England; and it is often remarked with surprise, of Irish peasants of the humblest appearance, that they possess an acquaintance with the classics and the elements of geometry.\* Till 1831, education in Ireland was chiefly left to private enterprise and the efforts of a few religious societies: the government in that year established a Board for National Education, which has since been a channel for the application of a considerable amount of public money to this purpose. In 1835, a return to the Commissioners of the Education Board gave a computed total of children attending school in Ireland at 633,946, the population being at the same time computed at 7,954,100; so that the proportion under school instruction appeared to be about 1 for every 12.5 inhabitants. Since then, the national system has made great advances. The following synopsis, drawn up from the reports of the Commissioners, shows the progress down to December 31, 1848:—

Reports of the Commissioners of Education.	Number of Schools in actual operation.	Number of Children on the Roll.
1834, . . .	789	107,042
1836, . . .	1181	153,707
1838, . . .	1884	169,548
1840, . . .	1978	223,560
1847, . . .	3825	402,632
1848, . . .	4109	507,469

The average number of pupils in each school is 125, and it is hoped that this will increase as the prosperity of the country revives. The number of applications for grants to new schools in 1848 was 636, of which 402 were granted and 234 rejected. The total amount of salaries paid to teachers for the year 1848 was £57,013, being an increase of expenditure, as compared with the year 1847, of £6621. The appointment of paid monitors has been found a very successful experiment, and the number has accordingly been increased, the salaries varying from £4 to £7 a year. The Irish

\* Of an edition of Euclid published by the editors of the present work, by far the largest proportion of copies is sold in Ireland. Mr Bichens, in a report on the Poor-Laws, asks, 'Where in England could the ordinance surveyors find persons amongst the lowest class to calculate the sides and areas of their triangles, at a halfpenny a triangle, as they do in Ireland, and plenty of them?'

national system at first met with great opposition, in consequence of religious party-spirit; but this obstacle, we are happy to observe, is gradually giving way.

Education is actively conducted in America, and it is calculated that about a seventh of the population are at school. In most of the states, schools are supported by a tax on property, and the superintendence is intrusted to committees of the rate-payers. In those of New England, the schools are as one to every two hundred of the inhabitants—a proportion, perhaps, exceeded in no part of the world. The education imparted is under a general, not party or sectarian management; and every attempt made by religious denominations to acquire a special control over the public schools has been promptly checked. The affected belief that this unsectarian education would lead to irreligion and discontent has been completely falsified. 'It is acknowledged by the rich,' says Sir Charles Lyell in his recent 'Visit to the United States,' that when the free schools have been most improved, the people are least addicted to intemperance, are more provident, have more respect for property and the laws, are more conservative, and less led away by Socialist or other revolutionary doctrines. So far from indolence being the characteristic of the labouring-classes, where they are best informed, the New Englanders are rather too much given to overwork both body and brain. They make better pioneers when roughing it in a log-house in the backwoods, than the uneducated Highlander or Irishman, and the factory girls of Lowell, who publish their "Offering" containing their own original poems and essays, work twelve hours a day, and have not yet petitioned for a ten-hour bill.

In surveying the statistics of education, we must keep in mind a few considerations by which the character and effects of education are liable to be much affected. Education is not certain to produce good effects, but only those which its directors contemplate and seek to bring about. It is a means of conferring certain accomplishments upon the mind, and modifying it to certain ends, inclinations, and habits of thinking and feeling. Its efficacy, even where well directed, is liable to be greatly modified by the character of the people amongst whom it is operating: for instance, a European people of good stock, and amongst whom all refining social agencies have long been at work, will show better results with a certain apparatus of school instruction, than a people newly emerged from barbarism. Above all, our expectations of moral results must be governed by the degree in which the moral department of education is attended to. Intellectual education gives only aptitude and information; it requires a training of the moral being, of the heart as well as head, to produce good conduct.

It has been seen that Prussia stands at the head of all the countries adverted to, with respect to the proportion of the population attending school. It is excelled in this respect by the United States of America, where, it is computed, there is a school for every 200 souls. England and Scotland have probably a ninth of their inhabitants at school—a considerably smaller proportion. But reckonings of schools and scholars are only a means of ascertaining a portion of educational influences. It cannot be doubted that, besides all the benefits, such as they are, of school learning, the youth of this country enjoy an immense advantage in the influence which the free institutions, the humanity, and the tone of mind resulting from an old-established civilisation, must exercise upon them. In a national system of education, the central government should possess but a slight, if any influence, and the business of both arranging and supporting should be left as much as possible in the hands of the people themselves. We beg to submit the following general views on this subject:—Anything done by government, as the organ of society, to promote universal education, must be based upon the actual state of educational efforts in the country. The people must everywhere be encouraged, invited, stimulated, to take a portion of the task of edu-

## POPULAR STATISTICS.

education into their own hands. With communities, as with individuals, education cannot be a one-sided matter, in which the instructor arouses the pupil; there must be exertion on the part of the latter also. The mistake of some governments, especially the Prussian, has been to hold the people as entirely passive: they have drilled rather than educated. Almost everything that has been hitherto done in Great Britain to promote education has been the result of private enterprise: even the majority of endowed schools are the fruits of private enthusiasm in the cause of education. A paper by Mr Long, in the second volume of the 'Journal of the Central Society of Education,' estimates the annual income of endowments in England, for purposes of education, at £1,500,000; and shows the want of a proper power, invested in some individual or body, for the purpose of assisting, directing, and correcting all who are intrusted with the management of such charity property. Educational amateurs may be deficient in skill, but funds left to support schools require some one to administer them, and to adapt the mode of dispensing them to the perpetually altering circumstances of society. A table of the Mechanics' Institutions and other popular associations in England for promoting and diffusing science and literature, has been published in the 'Statistical Journal.' It is defective, but it shows approximately what has been done by private effort for the higher education of the people. The total number of societies is stated to be 112; of 91 of these the annual income has been ascertained, and it amounts to £36,793, 14s. This is a slender provision for the intellectual wants of the adults of England, and what is more, its influence is limited in a great measure to those who, strictly speaking, do not belong to the working-classes. In the Glasgow Mechanics' Institution, a majority of the attendants on the lectures are shopmen, individuals employed in warehouses, and even some students—the middle-classes. Of the operatives who attend, the mechanics form a considerable proportion. The Mechanics' Institution of Liverpool, one of the most flourishing institutions of the empire, is, both in its elementary schools and its lectures for adults, frequented and supported almost, if not quite, exclusively by the middle-classes.

The facts mentioned seem to justify these conclusions:—That national education requires the operation of government only as public trustee, and of the people themselves, trying to procure the kind of education their wants prompt them to seek; that the duty of government is to insist that education shall be universal, and to provide such superintendence and means of general control as are necessary for enforcing this precept; that the duty of the people, in their respective districts, is to carry into effect the general directions of government. The business of government is to see that the necessary funds are provided, the necessary establishments for training teachers and pupils kept up, and the attendance of children enforced. The business of the people is to appoint teachers, and to take precautions for their discharging their duties conscientiously. The details of tuition are best left to the teachers, care being taken that they are previously educated for their profession. Success in teaching depends, in a great measure, upon the enthusiasm and ability of the teacher; and the most successful method is that which is best adapted to the peculiar character of the teacher. Some teach more efficiently by one method, others by another. The public judge most correctly of a teacher's ability by looking at results—at the kind of scholars he turns out. Some such organisation of the whole country for educational purposes, as is indicated in these general terms, would, by giving a controlling power to government, insure equal diffusion of education; by leaving to the people the appointment of teachers, and by leaving, to a certain extent, to individuals the choice of what should be taught, would keep alive the interest which men take in their own handiwork; and by leaving the methods to the choice of well-trained teachers, would give scope for progres-

sive improvements being effected in the art of education by those who were practically acquainted with it. The importance of leaving a certain latitude of choice to individuals (parents, or the more advanced young men or women), is apparent from the experience of the Glasgow Mechanics' Institution. The most uniformly successful classes have been those of mechanics (or natural philosophy) and chemistry; and a large proportion of the operatives who attended them have been engineers, and others engaged in processes which are best conducted by those who understand something of their principles. Human beings are most easily seduced to undergo the toil of learning (for though to pick up fragments of information be agreeable, to devote the continuous attention necessary to understand a subject thoroughly is at first a task) by the conviction that what they are learning can be turned to profitable account. Having learned one subject thoroughly, they acquire a liking for the effort, and are more easily induced to extend their researches. It is sound philosophy not to attempt too much at first. Get every one to learn something that may benefit him in his occupations; none, who have learned this thoroughly, be it what it may, will stop there.

### CRIME.

Crime is the result of various causes—as, first, the natural or original disposition of the culprit; second, the moral atmosphere in which he has lived; and third, the temptations placed before him. Generally, all of these causes are more or less concerned in crime, so that it becomes a very complex question. When we apply statistics to the investigation of crime, we are met by the further difficulty, that only a certain portion of the whole of the offences committed are known to us, and that the proportion known must vary in different countries according to the efficiency of the legal apparatus applied to the detection of crime. Statistics has, nevertheless, afforded some curious and valuable knowledge on this subject.

The number of persons annually committed or bailed to take their trial in England and Wales, has for a number of years past been rather on the increase; but chiefly, it is believed, in consequence of the increased efficiency of the laws. For the five years before 1839, it was 22,174 on an average; in 1840, it was 27,187. The last sum was an increase of 45 per cent. on the number for 1830, which was 18,657. In 1842 the number was 31,309; in 1843, 29,591; in 1844, 26,542; in 1845, 24,303; in 1846, 25,107; and in 1847, 28,833. It is important to observe, that these are not summaries of the whole offences of their respective years. There is, besides, a larger number of offences, which are tried summarily before magistrates. For example, in 1837, in addition to 17,090 persons convicted upon regular trial, there were 59,374 summary convictions.

By far the greater proportion of English crimes are against property. Taking the average of the five years before 1839 (22,174), it appears that 84.5 per cent. were thefts and frauds, the small proportion of 7 per cent. of these being accompanied by violence. Of offences against property and person, in which malice was involved, as murder, maiming, arson, and injuries to cattle, there were about 6 per cent. A class called sexual offences gave 2, and offences against the State, in which was included coinage, 6½ per cent.

The counties in which committals are year after year fewest are those of Wales, the four northern ones, Cornwall, and Derby; those in which they are most numerous are Middlesex, Essex, and Warwick.

There are some crimes which women are not, from various causes, liable to commit; but the gentler does not appear to be the honester sex; for the proportion of female to male committals for theft without violence, is as 84 to 73 per cent., a difference of one-sixth against females.

In the inquiries which have been made with regard to the age of offenders, wonderfully uniform results have been found, as will appear from the following table, giving the centesimal proportion at each period of life:—

CHAMBERS'S INFORMATION FOR THE PEOPLE.

	1836.	1837.	1838.	Greatest Difference.
Under 12 years, . . .	1 84	1 52	1 58	0 32
From 12 to 16, . . .	9 71	9 72	9 72	0 21
... 17 ... 21, . . .	29 03	29 23	29 13	0 20
... 22 ... 26, . . .	31 42	31 74	31 24	0 50
... 31 ... 40, . . .	14 43	14 56	14 75	0 32
... 41 ... 50, . . .	6 76	6 65	7 02	0 37
... 51 ... 60, . . .	3 33	3 24	3 00	0 33
Above 60, . . .	1 40	1 55	1 58	0 18
Not ascertained, . .	2 08	1 79	1 78	0 30
Total, . . .	100 0	100 0	100 0	

The large proportion at the periods of adolescence and youth must be considered as strictly owing to a greater tendency to crime; for the proportions of human beings at those ages to the whole population are different, the persons from 16 to 20 being as 10 per cent., and those from 20 to 30 as 15 per cent., of the entire nation. It is calculated that amongst the persons living in England and Wales, from 17 to 21 years of age, there is one committal for 232; while from 41 to 50 there is one for 941; and above 60 one for 3391 individuals. We thus see how great an influence the strong and unregulated feelings of youth exercise in inducing criminality.

The connection of education or non-education, and of poverty, with crime, has excited much attention during the last few years. It is abundantly clear that some school-learning may exist where the moral department of education has been neglected, or where the temptations to error may be very great. The education of mere reading and writing may only supply the means of committing a crime—as forgery—instead of tending to restrain from it. Yet it certainly does appear that criminals are generally uneducated in all ordinary respects. Mr Rawson, secretary of the Statistical Society of London, has found that, of every 100 offenders in England and Wales, 35 4 per cent. could neither read nor write; 54 2 per cent. could read and write imperfectly; 10 could read and write well; and only 4, or less than a half per cent. had received a good education. In Scotland, a late return showed that out of 8907 offenders, 20 2 per cent. could neither read nor write; 59 2 per cent. could read and write imperfectly; 18 2 per cent. could read and write well; and 2 4 per cent. had received a superior education.

Mr Bentley, author of a History and Directory of Worcestershire, has shown the relation of non-education to crime in a different way. It appears from his tables, that the six English counties having the greatest proportion of schools are Cumberland, Durham, Middlesex, Northumberland, Rutland, and Westmoreland, in which the schools are one for every 727 inhabitants, and the criminal offenders one for every 1156 inhabitants. The six counties that have the smallest proportion of schools are Chester, Dorset, Hereford, Lancaster, Northampton, and Somerset, in which the schools are one for every 1540 inhabitants, and the criminal offenders one for every 528; that is, out of a people having twice the number of schools, there is not in proportion half so many criminals as where the schools are deficient. A comparison of the number of schools in the six most criminal, and the six least criminal, of the English counties, leads to the same conclusion. In Essex, Gloucester, Hertford, Chester, Somerset, and Warwick, we find one criminal offender in the lists of government for every 499 inhabitants, and only one school for every 1069 inhabitants; on the other hand, in Cornwall, Cumberland, Derby, Durham, Northumberland, and Westmoreland, we have only one criminal to every 1309 inhabitants, while we have one school for every 839 inhabitants. In other words, there are six counties in England which have nearly three times the amount of crime found in six other counties; and the counties in which the least crime is found have one-fourth more schools than the counties in which crime abounds.

The different distribution of educational acquirements among the convicts of England and Scotland is striking, and requires for elucidation some inquiry into the proportional diffusion of knowledge among

the whole community in each country. Among the affluent classes, it is much the same, but among the working-classes it is materially different. According to the factory returns, there exists a more widely-diffused instruction in Scotland than in England: in the former country, out of 29,486 operatives, 95 8 per cent. could read, and 53 per cent. could write; while in the latter, out of 50,497 operatives, only 86 per cent. could read, and 43 per cent. could write. We have seen above that, in proportion as education was diffused through the whole community, the proportion of criminals to the total of the population was diminished; and this holds good in Scotland. But the mere extension of intellectual education to individuals of a class in which improved economical circumstances and self-education in moral respects has not induced that moral sense shown to be elicited in civilised communities, does not raise these individuals to the same elevation in the moral scale that the same education would do under more favourable circumstances. To produce the full benefit of education, it is the *class*, not merely the *individual*, that must be educated. An educated individual, belonging to an uneducated class, either continues to associate contentedly with his original companions, and retains their comparatively low standard of morality, combined with the increased power lent him by education—he has as feeble a restraint upon his conduct as they have, with much more power to do harm—or he attempts to associate with those above him in circumstances, though only equal in acquirements, and, failing in the attempt, sinks down to his former social level, soured against society, and prepared for any act of outrage. The petty pilferers are for the most part supplied by the destitute and uneducated class; the more daring and dangerous offenders by those who have moved in a more affluent sphere, and fallen from it by their imprudence or vices. The lesson conveyed by the different degrees of education possessed by Scotch and English criminals, is the necessity of educating *classes* as well as individuals.

When we come to speak of educating classes, we are brought to the consideration of their economical condition. In Bristol, an inquiry into the educational statistics of the city showed that, out of nearly 10,000 adults, taken indiscriminately among the working-classes, 22 5 per cent. could neither read nor write; 25 6 could read only; 51 9 could read or write. In a wretched part of the parish of Marylebone in London, it was found that 25 per cent. could neither read nor write, and 75 per cent. could either read, or read and write; and in two other portions of the same parish, inhabited principally by Irish labourers and their families, 49 per cent. could neither read nor write, and only 41 per cent. could read, or read and write. Among 1022 able-bodied and temporarily disabled paupers above the age of 16, the inmates of several Union work-houses in Norfolk, Suffolk, and Kent, whose attainments were ascertained with precision, 46 5 per cent. could neither read nor write, 18 read imperfectly, 30 2 read decently, 5 3 read in a superior manner; and of the same, 66 4 could not write, 15 4 could write imperfectly, 16 9 write decently, and 1 3 write well. It would appear, then—taking statistics in their present imperfect state as our guide—that poverty and want of education, as well as crime and want of education, are intimately if not inseparably associated.

On the last point it is necessary to guard against a misconception. There may be a district poor in resources and with respect to the style of living of the inhabitants, and yet crime may not abound in it. The department of Creuse is one of the poorest in France, yet it presents the fewest crimes. M. Quetelet draws the important distinction, that a set of people living steadily on small means, but knowing no better, and contented with what they have, are not poor, in the sense in which a people are poor who, seeing wealth and luxury around them, and exposed to the severest sufferings from the occasional failure of employment, are thereby demoralised.

## EDUCATION.

TILL within the last few years, the idea commonly entertained with respect to general elementary education, comprehended only certain branches of instruction familiarly known by the terms *reading, writing, and arithmetic*. A 'liberal' education added ancient and modern languages and mathematics. Such formed the entire round of accomplishments which were supposed, with the accident-directed moral training of the domestic circle, to be sufficient to fit the youth of even the highest classes for entering upon the varied duties of life. Nor was this scanty education thought requisite for all. A vast class was allowed to exist without the least tincture of school learning of any kind, as not being supposed to require any knowledge beyond that which immediately fitted them for the laborious duties by which they earned their bread.

The active period which has elapsed since the conclusion of the last war (1815), has been distinguished by nothing more than by the enlargement of our ordinary ideas with respect to education. It may be said to be now universally acknowledged that all—all, from the peer to the peasant—ought to be educated, however there may still be differences of opinion as to the *means* of educating, and what education should consist of. It is also generally admitted that *reading, writing, and arithmetic*, even when effectually taught, constitute but a branch of education, being merely instrumental accomplishments, the acquirement and cultivation of which tend in a certain degree to improve the intellect. The study of the ancient classical languages, while still admitted by candid persons to be also a means of improving the intellect, is now no longer upheld, excepting by a few, as the grand instrument of liberal education, the character in which it was generally regarded a few years ago. It is now seen that this study gives to the youth of the middle and upper classes but a portion, and in many instances not the most requisite portion, of what they should know on entering the world. The old elements of education may therefore be said to have sunk from their former character of all-sufficiency, and to have now taken their place as only parts of a complete education.

The primary meaning of the term *educate*, from the Latin *educare*, to lead or bring out, does not ill express the first great principle of the science. It may be held to assume that the human being is naturally in a comparatively rude and inert condition, and that external forces must be applied to draw forth his faculties into their full activity and power, and bring them to their highest degree of refinement and nicety of application. This is, in reality, a large part of the business of education, taking even the widest view of its purposes. A full definition would further include the regulation and discipline of those moral feelings on which our actions are mainly dependent, and also the communication of such sections of knowledge as the circumstances and prospects of individuals may render necessary.

Before correct views can be entertained with regard to education, or proper steps can be taken for working it out in practice, it is obvious that a distinct notion ought to be attained as to the character of the being to be educated. Man is this being; but the question 'what is man?' is one to which science does not yet enable us to give an answer that all would acknowledge as right. For this reason it is totally impossible for any writer to present a theory of education which would be generally received as a perfect science. The subject must needs partake of the obscurity and uncertainty which as yet rest upon at least the mental character of man; and it will only advance in clearness

and precision in proportion as progress is made in a correct system of mental philosophy.

While fully acknowledging the difficulty under which every candid writer on education must lie, the present would humbly endeavour to make the nearest approach to a correct system which his views of the natural character of the human being will admit of. He considers the race as exhibiting a definite mental constitution, in all its parts harmonising with the surrounding universe. He considers this constitution as embracing a variety of faculties, for sensation and action, which it is the business of the educator to awaken, strengthen, and regulate, so that each person may arrive at the best condition of which his character is susceptible, and most thoroughly fulfil the design of his being in all its various respects. He views, in the first place, the faculties of the physical frame as requiring to be duly exercised, so as to bring them to the utmost limit of their native power and health. Of the mental system, he views those faculties which constitute the intellectual powers as requiring to be drawn out, exercised, and instructed, so that they may operate readily and efficiently for all the various purposes which they are designed to serve; and those, again, which constitute the moral feelings as calling for the exertion upon them of all external moral influences—at the head of which stands the revealed will of God with regard to human destiny—in order that the best possible state of feeling may be attained with regard both to the affairs of the present and to a future state of existence. Upon these views of man's character a scheme of education may be founded, which rational persons, as yet unprepossessed by other notions, will, he thinks, generally acknowledge as accordant with common sense, however unprepared they may be to trace it to its foundation. He will therefore, without further preface, proceed to describe such a scheme, adopting the appropriate divisions into *physical, moral, and intellectual*, and combining, as far as his space permits, practical directions with what may be called the philosophy of the subject.

### PHYSICAL EDUCATION.

The object of physical education is to insure, as far as possible, that sound and vigorous frame of body which, while all must feel it to be one of the greatest of blessings, appears to be an essential concomitant of a sound condition of the mind itself. Physical education comes into operation before any other department, for one of its first concerns is to take care that the human being shall be brought into the world in the enjoyment of a perfect organisation. The mother is here the educator. She is required, during pregnancy, to order her life, with respect to food, dress, and all other habits, according to certain rules, found to be conducive to the welfare of her future offspring. Judicious medical men recommend that at this time the food taken should not greatly differ from what is taken at other times. The dress should be loose and easy. Moderate exercise should be regularly, as far as possible, indulged in; and it is of the greatest consequence, that while ordinary duties are attended to, a quiet, cheerful, and easy state of mind should be maintained. Departure from these rules, indulgence in late or otherwise irregular hours, and exposure to the excitements produced by violent passions, or the frivolities of fashionable life, are calculated to occasion deplorable effects on the being yet to be brought into the world.

INFANCY.—The physical education of an infant involves simply the means of keeping it in health. For this purpose nature has made one signal provision, in

the tenderness which she has infused into the female heart—a feeling which insures an unflinching kindness towards the young. But something besides kindness is required to rear children successfully. It is necessary that those who have the duty of nursing the young, whether mothers or substitutes for mothers, should have some knowledge of the physiology of the infant body, or at least be acquainted with the rules of management which result from such a knowledge. The sad effects of ignorance on this subject are sufficiently conspicuous; for we cannot doubt that, of the great mortality of the young (about four-tenths of them dying under five years of age), much is owing to erroneous methods pursued in the nursery.

Here the leading rules only can be indicated. An infant should never be plunged into cold water, or exposed in any other way to cold, because, the circulation being comparatively languid in the infant subject, he can less endure cold than grown-up persons; and an attempt to produce hardness may only undermine health. It is of the greatest consequence that an infant should be kept constantly clean and dry, that its hours be early and regular, and itself be as far as possible habituated to a periodic recurrence of all its wants. The mother's milk is the most appropriate food; next, that of a nurse about the same time confined; next, cow's milk warmed and diluted. Farinaceous, or any other kind of solid food, is unsuitable to the stomach of an infant under six months old. A child ought, if possible, to be nursed about eight months, and somewhat longer if weakly, or when the period of eight months terminates in the dead of winter. After weaning, the food should be farinaceous—that is, of substances composed of grain, potatoes, arrowroot, &c. Animal food should be avoided till the period of infancy may be considered as nearly at an end, and even then it should be of the tenderest fibre, and administered in very simple forms and moderate quantities.

The food and general habits of the nurse are of great and direct importance. The child is immediately dependent in all respects upon the person who suckles it; thrives with that person, and also declines with her; suffers when she suffers, and is well when she is well. So remarkably is this the case, that an act so simple on her part as the taking of a hasty draught of cold water, will probably give the infant a stomach-ache within two hours. It is therefore of the greatest consequence to the welfare of the young, that those from whom they draw their sustenance should observe all the rules proper to their condition. A nurse should live a quiet and regular, but not inactive life, using simple wholesome diet, avoiding stimulating drinks, and preserving, as far as possible, a cheerful mind. Fermented liquors, as porter and ale, are only to be resorted to when her strength would otherwise sink under exhaustion of her system. In ordinary health, a light beer is perhaps the most suitable beverage.

For the due development of the muscular system of an infant, its dress should sit light and easy upon its person, and its limbs should be allowed free play on all possible occasions. The restless movements of an infant, the tossing about of its head, arms, and limbs, are to be considered as merely impulses of nature, directing it to exercise, and consequently strengthen, its muscular system. These movements should therefore be rather encouraged than repressed. Care should be taken that it is not too soon allowed to bear its own weight, as the natural consequence is bending the as yet soft bones of the legs, which may thus become deformed for life. Whenever a child of proper age is unable to bear its own weight, or walk without this effect following, we may be sure that its general health is defective; and it is a more immediate and pressing duty to take measures for remedying this defect, than to attempt to keep the limbs straight by mechanical appliances.

The general health of an infant may be described, in a word, as to be secured (supposing a good constitution at first) by food appropriate to its organs, warmth, cleanliness, regularity in sleep and other wants, a well-

aired nursery, and occasional walks out of doors, protection from all injuries through the medium of the nurse and otherwise, and the muscular exercise of which its system is capable. (\*)

**CHILDHOOD, YOUTH, AND MANHOOD.**—Physical education ought to be continued till the body is brought to the utmost degree of perfection, in all its functions, of which it is capable. The improvement of all the systems and functions of the body may be called the *education* of these systems and functions; hence recent writers on the subject speak of the education of the skin, the education of the lungs, of the digestive organs, of the muscular frame, of the brain.

In a former number of this work—that on the **PRESERVATION OF HEALTH** (No. 45)—most of the matters which fall under Physical Education are carefully treated. By reverting to that paper, the reader will find of how much importance must be the formation of habits of bodily cleanliness, seeing that the skin is a system which only can have a healthy function when it is thoroughly free from impurities, and that nothing is more indispensable for general soundness than the particular health of this part of our frame. In the same paper, the value of a due supply of pure air for the health of the respiratory organs is insisted on; as also the proper regulation of the appetite for food. The education of the muscular system implies a competent knowledge of the structure, attachment, and conditions of action of the muscles; the operation of arterial blood and nervous influence on the muscles, and other matters, for which we refer to our number (8) entitled **ANIMAL PHYSIOLOGY—THE HUMAN BODY**.

Under this branch of physical education falls all the science of exercise—walking, riding, running, leaping, swinging, skating, dancing, fencing, cricket, ball-play, &c. The importance of these to health, in the full development of the muscles and improvement of the frame, has long been known, and by some nations steadily practised. The perfect forms of the Greeks and Persians were the result of this branch of education receiving a large share of national attention. Ample provision for such exercises should be made in all seminaries of education, infant and more advanced. What are strictly called gymnastics are more violent and trying than any we have mentioned, consisting of climbing poles, leaping bars, swinging by the hands, and maintaining difficult positions. These require much caution in the watchful educator, and should not be allowed in slender and weakly boys. They ought not to be overdone by any youth whatever, seeing that, even in the robust, strains and ruptures have been occasioned by them. (See **GYMNASTICS**, No. 95.)

#### MORAL EDUCATION.

The training of our moral nature for the due performance of our part as members of society, is that branch of education which the great majority of those who have reflected on the subject consider as by far the most important. It is a great mistake to suppose that this is a branch which the advocates of improvements in education have generally overlooked. As far as we have observed, all but a small sect of this class of philanthropists acknowledge its paramountcy. This is the part of education which, in a national system, would call for the most attention, because, while degrees of intellectual attainment are proper for different classes of men, there is no class of whom it can be said, that a *right and perfect moral development* is not of the utmost consequence both to themselves and the society of which they form a part. Beside such a benefit, that of an acquaintance with the mere elements of literature sinks into insignificance. There is no need,

\* The numbers introduced in this manner refer to volumes of *Chambers's Educational Course*, according to a list (as far as published) given at the close of the section 'Intellectual Education.' It will be understood that the volumes referred to either treat that department of the theory and practice of education fully, or is a school-book in which the subject is embodied.

however, to exalt any department of education at the expense of another. It may be true that intellectual development is not expressly moral development; but it must be clear to every candid person that the refinement and expansion of mind obtained from intellectual culture are favourable to the moral nature. A thinking man is not on that account likely to be the less a virtuous man; else much of our common observations of life must be a blindness and delusion. We would therefore say, let no department of education be considered as calling for exclusive or disproportionate cultivation; but let all go on in harmony together.

Moral education can have no definition from us but the development and regimen of the moral nature of those who are to be educated. Of the perplexity which attends this part of our being, it is unnecessary to speak. Let us only see if we can settle upon any principles by which it may be beneficially affected. It appears to include a variety of native feelings, of various strength and tendency to activity in every different person, yet all of them liable to be acted upon by appropriate external means, to good as well as to evil. In a mind totally untrained, the good dispositions are not without some energy; but generally, where there is a want of regulation of the feelings, and of certain principles to which the character of emotions and actions may be referred as to a standard, the moral being is a scene of deplorable confusion—the more so, of course, in instances where there is a considerable natural endowment of the inferior feelings. We have then the coarse, sensual, and selfish conduct which has been the mark of the rude and uneducated throughout all ages. On the other hand, we cannot doubt that many natures, not originally of a high cast, thrown under influences which tended to check the less worthy tendencies, to strengthen and develop the good, and to induce regularity over all, must have been thereby enabled to pass through life in a creditable manner, if not with some higher result less open to observation.

One principle thus strikes us at the outset as of very great consequence—namely, the circumstances, or, so to speak, the moral atmosphere, in which the being to be educated is placed. It is but matter of every-day observation, that a child reared amidst gross scenes, where no restraint is imposed upon any of the feelings by those around him, will prove, in all likelihood, a very different being from one brought up amidst virtuous and gentle people. Such a difference, we cannot doubt, would exist even where no attempt has been made by the latter parties to fashion the moral character of the young creature committed to their charge. It is exactly a difference of this nature which exists between the youths native to the vale of the Missouri (or those of the not less savage classes which social circumstances produce in most great cities) and those of civilised countries in general: circumstances decide the one set to be barbarians, and the other to be tolerably well-behaved persons. This *education of circumstances*, though so powerful, is unfortunately not always within the command of well-meaning parents. Individuals are here generally able to do little of themselves, if the persons by whom they are necessarily surrounded be not of the character that is desirable. Thus it often happens that a poor though well-disposed man is obliged to live in a part of a city where his children can only breathe moral contamination; and we can scarcely imagine a greater hardship. Yet these are just reasons why every effort should be made to promote a universal improvement of society; and it must rarely happen that some arrangements cannot be made, of a character likely to operate favourably on the young persons who are the objects of care.

We would here impress the importance of removing temptation as much as possible out of the way of young persons. There is a notion amongst some that a little temptation is not amiss, as a means of training the young to withstand greater assaults. But this is, we are convinced, an ill-founded doctrine, and most fatal policy. It is of the nature of every one of our feelings

to be awakened into activity by the presentation of its appropriate object; and it is the equally natural result, that the frequent activity promotes the power and the tendency to activity of those feelings. By presenting, then, what are called temptations, we are taking a direct means of educating and strengthening the inclinations towards error. On the contrary, a feeling allowed to lie dormant, loses in power, and becomes always less and less liable to act. There is perhaps a confusion of ideas at the bottom of the objectionable theory. The true plan seems to be to remove all actual temptation, but to give the intellect and the moral feelings proper warning against all such dangers, and thus prepare them for resistance when the time of unavoidable trial arrives. We would say, then, do not allow the young to see or touch evil things, or even to be in company where such things are to be spoken lightly of, from an idea that they are thus to be hardened against temptation. Be content to inspire a salutary horror of such things by your own report, if you only are so fortunate as to be able to keep your young charge exempt from positive contact with what is discommendable. An error may of course be committed in speaking too strongly against what you disapprove of, in which case the young person no sooner discovers the exaggeration, than, from a principle of contradiction, he is inclined to embrace the vice. But discretion will save from this mistake. Upon the whole, it may be set down as a most important rule in education, to reduce temptation within the smallest possible bounds.

Nearly connected with the education of circumstances is the *education of example*. Here personal conduct in the educating party is all in all. Children are remarkably disposed to imitation. They imitate instinctively, without having necessarily any discrimination of the character of the act which they are imitating. The general nature of their conduct is therefore ruled very much by the nature of the conduct presented to their observation. So much is this the case, that if a child be carefully watched, he will be observed to contract a tendency to scolding and beating, from that very discipline by which, most erroneously, an endeavour is made to correct his errors. It must obviously, then, be of the greatest importance that the demeanour and general actions of the educator, and of the family in which a child is reared, should be models of all that is proper. Just the more amiable and correct in all respects that this conduct is, so will the young be the more likely to form those habits which their best friends could wish. We will not pause to consider the effect which a positively vicious course of life is calculated to have on such of the young as witness it. The kind of bad example which we have here a chance of helping to abolish, is that which shows itself in acts far within the circle of positive vice. Such are the use of offensive and uncivil language, wranglings, domineering, low and sordid habits of all kinds. If parents and the other grown-up members of a family do not restrain themselves from all such acts in the presence of children, there cannot be a doubt that the children will likewise be addicted to them. It may be a somewhat startling doctrine, but we nevertheless declare our full conviction that there is not the least need for ever using, in the presence of or towards children, any language which might not be addressed by a well-bred person to a perfect equal. All ordering, dragging, scolding, and, much more, all violence, exerted for the purpose of managing, or punishing a child, are unmitigated errors and evils. A child has feelings to be wounded and roused up into contradiction by harsh usage, as well as any grown-up person; and it is well known that such means are not serviceable for gaining any end with our fellow-creatures. A civil request, if reasonable, will succeed with a child as with a man. Gentle and respectful language gain as much upon an uncorrupted child's nature as upon a man's. Such treatment can have no chance of *spoiling* a young person: it will only tend to his advancement as a rational well-bred being, instead of making him a wrangler or a tyrant.

The *preceptive part* of moral education, though the lowest in power, is not to be overlooked. A good maxim or a sound advice, well-timed, and made thoroughly intelligible and thoroughly acceptable, will rarely fail to have a good effect. Even supposing it to be little regarded at the time, it may remain in the memory, and come into play on some future occasion, when perhaps more necessary than now. In such moral seeds there is a vitality like that of the seeds of plants, which may have been buried too deep for germination for thousands of years, and yet, when placed in the proper circumstances, visited by sap and heat, will send up as goodly specimens of their kind as if they had been shed from a parent stem of last year's growth. It will therefore be proper, from time to time, to inculcate moral lessons appropriate to the capacity of the child. This may be done directly, by giving good maxims to be learned by heart; but it will be done better by means of narratives showing the virtues in action. This is because a child much more readily apprehends a series of incidents than an abstract truth. It will also be well to allow the simple narration, in the first place, to be received into his mind, and then to allow himself, if possible, to make out the moral. Call his own moral feelings, as far as may be, into judgment upon the case, and only tell him whether he is right or wrong, till he fully comprehends it in all its bearings. Thus his own good feelings, as well as his judgment, are brought into exercise, and thus a far deeper impression is made than if the whole case, including the moral, were merely related to him. (\*) It is a duty of preceptive education to warn against and check evil, as well as to inculcate good. When anything wrong is done, we but imperfectly correct it by saying, 'Don't do that,' or inflicting censure or punishment. It is necessary that we should convince the understanding and move the feelings of the child to a sense of the impropriety of his conduct. This may be done by mild argument and illustration, calling upon himself ultimately to say whether such conduct is commendable or not, and whether it ought to be repeated or avoided. He thus becomes judge upon his own case, and is forced to condemn himself, where, if condemned by others, his opposite feelings might have only presented resistance and defiance. At some schools, including those for infants, it has been found possible to impress such lessons by means of a kind of trial, the schoolfellows being the jury. The case is stated to the assembled children: they are asked to say if such conduct is right or wrong. They invariably give a sound decision, and the effect is most powerful. Obdurate natures, to which a reprimand from master or parent would at the moment be as nothing or worse, are found unable to resist the force of the *public opinion of their own society*—as is every day found to be the case with grown-up people, such being, in fact, a law of human nature.

Circumstances, example, precept, are all inferior in effect to *Training*, which is more particularly the novel feature of modern education. This principle may be said to have its natural basis in the law of habit. It is indicated in the text, 'Train up a child in the way he should go, and when he is old he will not depart from it;' and in the maxim, 'Just as the twig is bent, the tree is inclined.' We are so constituted, that when accustomed to do anything, we do it almost without the governance of our will or judgment. We do it easily, and generally well. If accustomed, for instance, to a particular class of intellectual operations, we acquire a facility in going through them which generally strikes others with wonder. If accustomed to the exercise of a particular class of feelings, be they good or bad, they in time awake unprompted, and we become their almost passive instruments. To habituate the feelings to the exercise and regulation which is productive of the best results, constitutes moral training.

\* The Moral Class-Book, here referred to, supplies a variety of narratives, showing the virtues in action, together with a selection of moral maxims from Scripture and other sources.

The feelings are of very various character. Proceeding upon Dr Gall's description of them, which seems to us to be the best, we find the first class described as selfish, yet necessary for the preservation of the individual and the species; others directed to objects apart from self, yet as liable also to misdirection and abuse. It seems altogether a strangely-mingled web, yet not without a certain definiteness of constitutional arrangement and of purpose. Here it may be at once admitted, as a fact not less obvious from philosophical inquiry than from revelation, that perfection in the complicated operations of our moral nature is not to be looked for. It is equally certain, however, that there are influences which may act advantageously in regulating, directing, and harmonising these operations.

The selfish or lower feelings are the first in the individual to call for attention, and they may therefore be first treated in this place. That early developed instincts which regards food is so liable to be over-indulged by a mistaken kindness, that we feel particularly called upon to give a warning with regard to it. The unavoidable effect of such over-indulgence is to produce pampering and fastidious habits, equally degrading to the moral as they are dangerous to the physical system. The food of the young should never be otherwise than simple, if we were merely to regard their health; still more should it be so, if we would preserve in them manly and hardy habits. On the rare occasions when a little treat is afforded, care should of course be taken that it is of a nature in all respects harmless. Comfits should be few and far between, if ever given at all; and rewards and punishments should never have reference to edible things. As to liquor of any kind, such as men are themselves but too much accustomed to indulge in, certainly one drop should never enter the lips of a young person on any pretext whatever. There are few sights more distressing to a reflecting mind, than that of parents handing the so fatal wine-cup to their children. The quantity of food given to the young should never be stinted from penurious or ascetic motives; but it is very certain that great errors are committed in giving too much and too frequently. Eating is altogether much a matter of habit, and that with regard to quantity as well as quality. The amount actually required for the efficient support of the system is, under natural circumstances, not great: it is generally much exceeded. There is therefore room for a judicious restriction, within the range of common practice. It is but a result of the general law, that a systematic moderation at this period of life will lead to an easily-maintained temperance in future days, and thus be productive of the greatest blessings.

The combative and destructive dispositions of children are also early manifested. The great activity of these faculties in boys is particularly remarkable, being shown as much in a wild spirit of adventure, for innocent objects, but often leading into danger, as in any direct form of violence. The superabundant vitality of this period of life seems to be a cause, or at least a necessary accompaniment, of the energy of these faculties. No peril intimidates; little compunction is felt in dealing with either man or beast. In all this there is no doubt a good end in view; but it still remains for the educator to regulate these dispositions. The *contendative* spirit may be directed to the overcoming of difficult tasks, the taking of energetic exercise, and the visiting of places and objects the examination of which may be useful. The other feeling, instead of being allowed to show itself in rage, passion, and resentment, to inflict pain on harmless animals, to torture or oppress companions, or take delight in defacing and destroying inanimate and perhaps ornamental or useful objects, may be trained to reserve actual manifestations of its energy for objects clearly noxious. It is to be lamented that education, as heretofore, and still in many places, conducted, rather tends to foster than to regulate or moderate this propensity. The old notion, that to be able to fight is essential to a youth, still, we fear, in some measure guides directors

## EDUCATION.

of education, at least so far as to induce their taking little pains to prevent scenes of outrage where only youthful good-humour and kindness should prevail. The oppressive system of flogging is also still, to the disgrace of our age, allowed in some of our public seminaries. It is well, no doubt, that he who is to find life a thorny and difficult path, should not enter it with too gentle or timid dispositions; but surely it is not impossible to draw a distinction between quarrels, blows, and tyranny, and the encouragement of a spirit sufficiently manly and energetic for all the common needs of our social existence.

The first object of the educator with regard to these feelings, ought to be to impress the lesson that their exercise is good or bad just as they have good or bad objects in view—that they must in all cases be under the guidance of the moral sentiments and judgment. The pupils should be trained to check every impulse of these feelings which they are conscious has not a legitimate object in view, and only to allow them any freedom when careful reflection has satisfied them that such a course is entitled to the entire sanction of the moral law. Particular regard should be paid to the suppression of the spirit of wanton cruelty, of malice, of revenge, of uncharitableness. And one important means of working out these ends will be to allow no example of harshness, cruelty, or quarrelsomeness ever to appear before the eyes of the young. It is very desirable that those who conduct schools in which the children of the humbler classes are educated, should address themselves particularly to the formation of habits favourable to humanity. Large sections of the humbler classes, particularly those who have anything to do with animals, are habitually cruel. Much might be done to mitigate this distressing characteristic by carefully impressing at school the wickedness involved in every description of cruelty to animals.

The secretive disposition calls for a large share of attention from those who would bring up a child well. This tendency of our nature appears to have a legitimate operation in dictating such a reserve as may be necessary for the restraint of our ordinary feelings, where their expression would be disagreeable or mischievous; but it is liable to great abuse, and particularly amongst the young. The first impulse of all unregulated minds, young and old, is to conceal the truth, if such expedient seem calculated to save them any harm or inconvenience. It is only when the greater evil of lying is thoroughly understood that this tendency ceases. It becomes, therefore, of great consequence to check the first instances that are observed in the young of a disposition to conceal the truth for selfish or base purposes, and to seek to establish principles and habits of a contrary character. For this end nothing is so necessary as a mild and just treatment of children under all circumstances, seeing that when severity or injustice is to be apprehended, a direct and far too great temptation is given for secretive conduct.

It is difficult to legislate between the evils of blabbing, and the equally notorious evils of a habitual system of conspiring for the concealment of truths which conscientiousness would direct being told. There can be little doubt that the 'don't tell' practices of the nursery and school are calculated to implant and foister the seeds of disingenuousness in the youthful mind. Yet it is not less true, that to encourage a tale-bearing habit would be destructive to all manly and honourable feeling. Here caution, judgment, and a careful discrimination of cases, must be the chief guides of the educator. We would for our part deem it a duty to lean as much as possible to the principle of having the truth told at all hazards. The educator may do much by a rigid system of inspection, and omitting no opportunity of breaking up all confederacies against the truth. As he never will allow *shirking*, if he can help it, so also he will never, on his own part, be guilty of the meanness of *winking*. The more open and candid his own conduct in all his relations towards his pupils, the better will it be for them. There exists a school on

improved principles, where the most lively mutual confidence exists between the masters and their pupils, and on the part of the pupils towards each other, with the best effects on all hands. Honour is thus so habitually observed, that the desks containing the little property, letters, &c. of the pupils need no locks. There is much evil in families from children being brought up in non-confidential habits with their parents and with each other. The family parlour and table should be a scene where all can unfold their ordinary thoughts without fear of censure or ridicule. It is the best means of insuring that the young people will act with the concurrence of their parents, when they come to take any of the more serious steps of life.

The acquisitive feeling requires much more educational care than it has usually received. We need not detain the reader with an exposition of the legitimate use of this faculty, which prompts man to accumulate or store up the goods of life, for regular instead of precarious use. To this impulse capital owes its existence, without which there could be no civilisation. The Author of our being has stamped importance on this faculty, by the strength of the propensity. None more requires modification, regulation, and right direction. It is often too strong for conscientiousness, and is the source of by far the largest amount of crime. But, besides this, it is even with the honest too much manifested in abuse. Its objects are made the paramount pursuit of life, and in its intense selfishness it withers to dust every generous and kindly feeling of the heart. In a commercial country like our own, it deeply degrades a large proportion of the community, and leads to much individual and social suffering.

These evils are the consequences of the natural strength of this feeling, the absence of regulating education, and the presence of positive mis-education. Selfish and exclusive appropriation of desirable things, either to eat or hoard, is a lesson taught the youngest, both by precept and example; and there is none more easily learned. Here bribery operates, till infant morality becomes mere matter of barter, and good conduct and attentive study are estimated by the infant merchant by what they will bring. Perhaps we err in so soon introducing children to the use of money; it is at least desirable that they should not be accustomed too soon, or at any time, to an engrossing sense of its value and importance. It is well to accustom them to take care of anything that is their own, but not to set too great store by their little possessions, or to be too exclusive in the use of them. A habit of scrupulous regard to the distinction between *mine* and *thine*, is one which cannot be too early formed, at the same time that children are accustomed to make a generous use of whatever is their own.

Self-esteem and love of praise or approbation are early awakened feelings, and the more call for regulation that they are so liable to be called into exercise by the procedure of education itself. Here it is particularly important to keep in mind what are the legitimate uses of these feelings. A well-regulated self-esteem obviously gives that confidence in ourselves and our powers which is necessary for all our efforts in life; while a moderate regard to the opinions of others is useful in prompting to such efforts, and in restraining us from many displays of caprice and absurdity to which we should otherwise be liable. It will of course be well to encourage these feelings, as far as they tend to give necessary confidence, and to maintain a decent regard for character in the world, but no further. Their vices, pride and vanity, too much reliance upon self, and too abject a regard to the world's opinion, are to be sedulously guarded against. In the procedure of education, they are so readily available as means of stimulating to exertion, and encouraging good (that is, not troublesome) behaviour, that it is not surprising that they are so extensively made use of for those purposes. The whole system of place-taking, prizes, medals, &c. is founded on them. It cannot be doubted that educators are thus guilty in many instances of

fostering invidious and even destructive feelings in those under their charge; the whole system is unquestionably a selfish one. Feeling strongly these objections, some modern educationists advocate the entire abolition of all marks of *emulatively comparative* proficiency or good behaviour at school, retaining only an accurate register of individual advancement, to enable the pupil to mark his own progress. Theoretically this is right; and we may hope that, when education is fully organized on a right footing, and supported by an improved adult society, the whole system of competition, including every kind of rewards and punishments, will be dispensed with. Meanwhile we must leave educators to act on these points according to their best discretion, only strongly recommending them to dispense as far as possible with all these inferior, and, to a certain extent, degrading and corrupting influences.

**Cautiousness**—a feeling intended, in its right direction, to prompt to foresight and the avoidance of unnecessary dangers, but in its excess, pusillanimity and cowardice—calls for a careful treatment. Amongst unthinking persons, it is mere sport to frighten children with narratives, objects, and exclamations calculated to inspire terror. Thus their imaginations are filled with bugbears, which harass them constantly, and make it the severest punishment to be left at any time alone, or to be in the dark. In cases where a predisposition exists, the most serious consequences sometimes flow from this irrational treatment. An enlightened educator never allows an ideal terror of any kind to enter the mind of his child or pupil. As the feeling may be strong or weak in the particular case, he seeks to moderate or to foster it, giving encouragement and stimulus if it be defective, and prompting to caution if it be otherwise. He carefully impresses the lesson that danger and hazard may be laudably encountered for a good object, but that it is folly to undertake the least risk when no end is to be gained by it. For example, he would approve of his pupil perilling his own life to save a friend from drowning, but not of his going across a lake thinly frozen, merely to make a demonstration of his courage.

The selfish feelings appear in a natural subordination to those which are usually called 'higher,' and sometimes, by excellence, 'the moral sentiments.' These are what mainly give the characteristic, 'goodness,' to an individual, and so rule the social machine, that general movements are usually of a virtuous character, and vice is obliged to remain in nooks and corners, or put on the garb of virtue when she appears. It is to the proper training and regulation of this class of feelings that the educator chiefly looks for the result he aims at—namely, the right formation of character.

**Conscientiousness**, the conscience, the moral sense, or by whatever other name it is called, is that innate feeling which gives the disposition to follow right and avoid wrong in all circumstances. To bring this feeling into its full force, it is necessary to train it with the aid of intellect to lend it discrimination. The pupil must be accustomed to observe its rules, as to the property of others, their reputation, their comfort and happiness, the right decision of every question in which their interests are concerned, and also with regard to the truth in all things. He thus becomes fixed in equitable, disinterested, and ingenuous habits, beyond all the powers of ordinary temptation. It will be no exercise to this sentiment to tell the young to avoid certain acts, because they are mean, and only practised by the vile, or because they will procure universal odium. That is an appeal to love of approbation, not to conscientiousness, to the development of which it will be rather unfavourable than otherwise. To fortify conscientiousness against what is wrong, we must directly address itself, by an endeavour to show the actual unjustice or baseness of any particular course of conduct, or the integrity and purity of the opposite; taking care to induce an act positively conscientious on all possible occasions, as in the acting upon a sentiment does the means of improving it chiefly lie.

So also with benevolence. We must not content ourselves with presenting ideal pictures of the distresses of our fellow-creatures to the minds of the young, thinking that to excite their commiseration is enough. We must endeavour to induce them to perform acts of kindness and charity—we must endeavour to make them give, from their own means, or at some expense of self-denial, succour to the unfortunate; and for this reason it will be proper that they are occasionally brought to witness cases of actual suffering, and made to administer relief with their own hands. It was a beautiful old custom of Christian princes and princesses, to have a number of poor persons occasionally brought before them, that they might minister to their relief and comfort by washing their feet with their own hands. It was its least good effect to humble rank to the level of mortality: the better one was to give activity to the sentiment of benevolence, too apt in such persons to become dormant, from their very elevation above all spheres in which human suffering exists. Benevolence is also to be shown in what is called an obliging disposition, a readiness to sacrifice ourselves and take some trouble whenever our doing so can at all promote the happiness of our fellow-creatures. It is likewise shown in mercy towards the weak, including animals, and in a forgiving placable temper. 'Teach your children,' says Mr Goodrich in his admirable treatise entitled "Fireside Education," 'never to wound a person's feelings because he is poor, because he is deformed, because he is unfortunate, because he holds a humble station in life, because he is poorly clad, because he is weak in body and mind, because he is awkward, or because the God of nature has bestowed upon him a darker skin than theirs.'

Justice and kindness to others have a worthy associate in respect or veneration for others who are of superior worth, and for superior objects in general, including the objects of religious faith. This is also a native sentiment of the mind, and one which sends a beautiful light throughout the world. The scoffing and undervaluing propensity is its opposite—a disposition rarely found associated with estimable qualities. The sentiment of veneration is that on which all social grades depend; it is the spirit of subordination itself. It is a folly when exercised with regard to mere artificial rank unattended by worthy qualities; but with regard to persons elevated either by their native good qualities, or the function which has been intrusted to them to execute, it is as much due as is our pity and succour for the unfortunate. It is perhaps this feeling which chiefly gives a regard for the feelings of others; for we must think our fellow-creatures of some consequence, before we will be disposed to go out of our way on their account. The feeling, therefore, eminently deserves the care of the educator; but great pains must be taken to give it right direction. We must teach the young to discriminate judiciously as to objects really entitled to their reverence. It may here be remarked, that the feeling of veneration is one which may prove of great importance in certain contingencies to which the educator is liable. When a child has been indulged or mis-trained to such an extent that he defies all the rems to which he has been accustomed, it will generally be found that removing him to a new scene, and into the charge of individuals who, whether from their character or from the force of novelty, excite the veneration of the young delinquent, is attended with a good effect, which it only requires firmness, discretion, and kindness on the part of the new teacher to follow up, for a complete reformation.

The above may be said to be the natural means of cultivating and forming the moral character of those intrusted to our hands. And these natural means are of great consequence, and entitled to all the respect we can give them; for they are in reality means of Divine appointment, designed to serve in the great work of mutual improvement. But the most powerful means of modifying human character is that other revelation which has come to us in a more direct manner, and

## EDUCATION.

which is fully disclosed in the pages of Scripture. As soon as this can be made intelligible to the young, it should be imparted, not under those rudely familiar circumstances which too often attend religious education in the school-room and at home, where the child is conscious of little besides a struggle to commit certain texts and dogmas to memory, but in the quiet of confidential converse, when the thoughts are called home, and the soul is open to awe, love, hope, and all the gentler emotions of our nature. Then may we hope to convey some just impressions of the grand yet tender relation in which man stands to his Creator, his destiny on earth, and the appointments for the future. Then only may we hope to impart just feelings with regard to the inscrutable scheme on which the weal or woe of an eternity depends. It is obvious that, if we succeed in these things, we must awaken in the moral nature a self-sustaining influence infinitely more powerful than precept, example, training, and all the other natural machinery of a moral education. Yet it should never be lost sight of, that neither means will singly be operative. Upon a mind which has been left rude and unregulated, the efforts which ultimately take the name of religious education can make little impression. The words which have been learned will probably remain only as words, without producing any real religious feeling, much less any improvement of conduct. Indeed, both the morals and the intellect must be cultivated to a considerable extent, before religion can be anything but a passing sound. There must be a prepared intellect to understand it, and prepared moral feelings to give it a reverential reception, and entertain its behests in the spirit due to them, not to speak of acting upon its precepts.

To recapitulate—the moral nurture of the young is to be accomplished by a variety of means: first, by placing them in a pure moral atmosphere, presenting what is good and nothing evil of human conduct before their sight, familiarising them with every sound precept, and giving their various feelings due regulation, exercise, and training; next, by imbuing them, under the circumstances most calculated to be effective, with those religious truths which so infinitely transcend all others in importance. In order to impress these lessons still more pointedly, we beg to append some express directions which we think may be advantageously followed in the management of the young, more particularly those at the infant stage:—

Anticipate and prevent fretfulness and ill-temper, by keeping the child in good health, ease, and comfort. Never quiet with giving to eat, or by bribing in any way, still less by opiates. For the first few months avoid loud and harsh sounds in the hearing of children, or violent lights in their sight; address them in soft tones; do nothing to frighten them; and never jerk or roughly handle them. Avoid angry words and violence both to a child and in its presence, by which means a naturally violent child will be trained to gentleness. Moderate any propensity of a child, such as anger, violence, greediness for food, cunning, &c. which appears too active. Show him no example of these. Let the mother be, and let her select servants, such as she wishes the child to be. The youngest child is affected by the conduct of those in whose arms he lives. Cultivate and express benevolence and cheerfulness; in such an atmosphere a child must become benevolent and cheerful. Let a mother *feel as she ought*, and she will *look as she feels*. Much of a child's earliest moral training is by looks and gestures. When necessary, exhibit firmness and authority, always with perfect temper, composure, and self-possession. Never give the child that which it cries for; and avoid being too ready in answering children's demands, else they become impatient of refusal, and selfish. When the child is most violent, the mother should be most calm and silent. Out-screaming a screaming child is as useless as it is mischievous. Steady denial of the object screamed for is the best

cure for screaming. In such contests, witnesses should withdraw, and leave mother and child alone. A child is very ready to look round and attract the aid of *foreign sympathy* in its little rebellions. Never promise to give when the child leaves off crying: let the crying be the reason for *not* giving. Constant warnings, reproofs, threats, and intreaties—as, *let that alone—be quiet—how naughty you are*, &c. all uttered in haste and irritation, are most pernicious. No fixed or definite moral improvement, but the reverse, results from this too common practice. Watch destructiveness, shown in fly and insect-killing, and smashing and breaking, quarrelling, striking, &c. Never encourage revenge. Never allow a child to witness the killing of animals. Counterwork secretiveness by exposing its manoeuvres. Regulate notions of property—one's own and another's. Never strike a child, and never teach it to strike again. Never tell a child to beat or threaten any animal or object. Corporal correction may be avoided by judicious substitutes. Set an example of cleanliness, order, punctuality, delicacy, politeness, and proper ease of manner. This is better than *teaching manners*, as it is called. Inculcate early, and manifest in yourself, a delicate regard for the rights of others and their feelings, in contrast with selfish vanity, arrogance, and exclusive attention to one's own ease, comfort, and gratification. Prevent all indelicacies and slovenly habits at table—touching the utensils, stretching for what is wanted, sitting awkwardly, &c. Study early to gain a child's confidence by judicious sympathy in its joys and sorrows. Have no concealment with it. Govern by love, and not by fear: the contrast between children governed by the one and the other is truly instructive. Never forget that kindness is power with man and beast. *The Arab never strikes his horse*. Cultivate truth, justice, and candour in the child, and manifest them in yourself. With a child whose firmness is apt to run into obstinacy, never contend; in doing so, you aggravate the feeling by manifesting the same feeling in yourself; and by further showing your combativeness, exciting the child's opposition. Divert the child from the object, and put in activity its benevolence, justice, and reason. Never frighten to obtain a child's obedience: threats of hobgoblins, and all false terrors, are most injurious in their direct effects, and being generally discovered to be falsehoods, operate most immorally.

We beg to conclude the section with the following remarks from Dr Combe's excellent manual for the management of infancy:—“It is a common and pernicious error in modern education, that the passions and moral emotions implanted in the human mind are the results of intellectual cultivation; that intellectual discipline will suffice to regulate them. Under this mistaken notion, parents are often disappointed and displeased with a child, when, after a full explanation of the impropriety of the feeling or passion, it still, on the recurrence of the temptation, gives way to it as much as before. I have known a father, under this false impression, lecture, and threaten, and punish his child, and take every way to correct it but the right one. Fortunately for mankind, however, morality and religion have a much more solid foundation than a mere deduction from an erring intellect. They are based on feelings implanted in the very nature of man, and which mere intellectual cultivation or neglect can neither generate nor destroy; and their real strength and authority will not be fully recognised, till they are cherished and developed in strict accordance with their natural constitution. Like the external senses, they must be habitually exercised upon their appropriate objects—in worshipping the true God, and in doing justice, and loving mercy—before they can attain their proper influence over the character, and their true authority in regulating human conduct. From almost the first hour of existence, this principle should be systematically acted upon, and the utmost care be taken to secure at all times a healthy moral atmosphere for the young. To do perfect justice to the infant, there is required,

on the part of the mother, a combination of cheerful activity, good sense, knowledge, readiness of resource, and unflinching kindness and impartiality, which is not often to be met with. But by aiming at a high standard, we shall make a nearer approximation to what is required than if we rest satisfied in indifference with whatever occurs. It is lamentable to reflect how numerous are those mothers who, from indolence or other causes, leave the entire control of their offspring to an unqualified attendant, and even themselves give way to expressions of anger or caprice, which cannot fail to act injuriously upon the infant mind. Let us, then, not deceive ourselves, but ever bear in mind, that what we desire our children to become, we must endeavour to be before them. If we wish them to grow up kind, gentle, affectionate, upright, and true, we must habitually exhibit the same qualities as regulating principles in our conduct, because these qualities act as so many stimuli to the respective faculties in the child. If we cannot restrain our own passions, but at one time overwhelm the young with kindness, and at another surprise and confound them by our caprice or deceit, we may with as much reason expect to gather grapes from thistles, or figs from thorns, as to develop moral purity and simplicity of character in them. It is vain to argue that, because the infant intellect is feeble, it cannot detect the inconsistency which we practise. The feelings and reasoning faculties being perfectly distinct from each other, may, and sometimes do, act independently; and the feelings at once condemn, although the judgment may be unable to assign a reason for doing so. Here is another of the many admirable proofs which we meet with in the animal economy of the harmony and beauty which pervade all the works of God, and which render it impossible to pursue a right course, without also doing collateral good, or to pursue a wrong course without producing collateral evil. If the mother, for example, controls her own temper for the sake of her child, and endeavours systematically to seek the guidance of her higher and pure feelings in her general conduct, the good which results is not limited to the consequent improvement of the child. She herself becomes healthier and happier, and every day adds to the pleasure of success. If the mother, on the other hand, gives way to fits of passion, selfishness, caprice, and injustice, the evil is by no means limited to the suffering which she brings upon herself. Her child also suffers, both in disposition and in happiness; and while the mother secures, in the one case, the love and regard of all who come into communication with her, she rouses, in the other, only their fear or their dislike.

#### INTELLECTUAL EDUCATION.

By intellectual education we hold it to be implied that the human intellect, originally a mere instrument ready to be exerted, requires, for the full development of its powers, and subsequently, for the ready use of those powers, the application of certain external stimuli, and the force and regulation of a certain discipline; also that the intellect, besides being thus improved in its own character and energies, requires to be possessed of certain knowledge and certain accomplishments, in order to a proper performance of the various duties of life. We shall not stop to make a nice investigation as to the various powers of the intellect and their modes of acting, but at once assume that, with senses serving as media for the access of impressions from the external world, it includes powers which can take cognisance of things, or perceive, and powers which can compare things, and trace their connection in cause and effect (reflecting); these having various modes of action recognised as memory, association, &c.; and that these various media, powers, and modes of operation may all be improved by use and exercise. (See HUMAN MIND, No. 71.)

Intellectual education properly begins with the first symptoms of consciousness in the infant—the first indications that the senses and internal observing powers,

the germs of which exist in the youngest infant, are beginning to operate.

The senses require the earliest attention of the nurse. Sight, hearing, and touch are, in a very short time after birth, in obvious activity; but they require at first to be very delicately treated. Exposure to bright lights, and sudden loud sounds, has produced blindness and deafness for life. Both senses should be brought on gradually. These, as well as touch, should then be judiciously exercised upon their own objects, placed at different and increasing audible and visible distances, till at great distances objects can be seen and slight sounds heard. Objects should also be touched blindfold, and discriminated. Smell and taste are improvable by similar means. It would form an extremely interesting occupation to an intelligent nurse, for many a moment of ennui which she now endures, in her care of an infant, to exercise its senses on their appropriate objects. When nothing is done, or when the child is shut up in a small room with no range of vision, not only is no progress made, but there is great danger of short-sightedness being either induced or aggravated.

Leaving the external senses, and advancing to the internal faculties of the mind—the powers of feeling, observing, and thinking—we may remark that the brain, which is as much the instrument of these powers as the eyes and ears are of their respective external senses, is at birth, and for some time after it, too imperfect and delicate in its substance for active manifestation. The desire of food, and sensibility to bodily pain, alone appear, and are indeed all that are then necessary. But the more delicate the brain, the more delicately ought it to be treated; for an injury to it may produce idiocy or imbecility for life. In the exercise and cultivation of the intellectual organs, it has been found, from experience, that great caution is required. It is here that the brain is most apt to be overworked; and it is here that that premature activity, called *precocity*, appears. Under the head *Precocity*, Mrs Barwell gives the following emphatic counsel:—'When a child appears to be *over-intelligent*, or too *clever* or *wise* for its age, this is a symptom of unnatural development of the brain; it is a kind of disease which often ends fatally. Avoid, therefore, exercising the child's *ability*; treat it as an animal, with nutritive food, muscular out-door exercise, and plenty of sleep; and do this, and *this only*, for some years.' We allude to the subject of *precocity* thus early, in treating of intellectual training, because its indications often appear in very early infancy, and erroneous treatment cannot be too soon avoided.

Before two years of age much important intellectual education is going on. It is not the education of books; it is gradual introduction to surrounding objects. How early the eyes are used to gaze at, and the hands stretched out to grasp and become familiar with, everything presented or observed, need not be here insisted on. A judicious nurse will direct this impulse of nature, and much assist this self-education, so that the earliest impressions may be made by such objects as form the materials of existence, and their qualities, never to be effaced in after-life; while the observing faculties will have a healthier growth, by means of an easy and pleasingly-directed exercise. Modern educationists have often complained of a prevalent want, in people of all ages, of what may be called *observativeness*—the power or rather habit of noticing what is before and around us. Multitudes pass through life, of whom it may be said that they have missed four objects in five which came in their way. This could be met in early infancy by taking the proper means of establishing habits of observation. 'Look here;' 'see this;' 'feel that;' 'weigh the other thing;' 'what beautiful colours;' 'smell that flower;' should be the simple and constant lessons of the nurse; and she would find both the intellect and dispositions of the child improved by such exercise. The contrast in after-life between children so trained, and those who never observe anything, would be both striking and instructive. (1)

## EDUCATION.

FROM TWO TO SIX YEARS OF AGE.—Intellectually prepared by the nurse up to the point at which we have arrived—when the child has reached the age of two years, and when, if it can by any means be so arranged, he or she should join an Infant School—the intellectual education will, so to speak, take a more scholastic form. The lessons will be somewhat more systematic, and suited for the simultaneous attention of numbers. But still the caution will never be lost sight of, that, from two to six, the intellectual exercises should be light and attractive, and never long continued at one time; air, exercise, and play, regularly alternating with instruction. The paramount object at that period of life, let it never be forgotten, is *moral* training; to which object companions of the same age, in considerable number, are as essential as light is to the exercise of the eyes, or air to that of the lungs. Benevolence, truth, justice, honesty, attachment, all imply companions. Although at that age the intellectual training is secondary when compared with the moral, yet, without tasking the infant faculties, without giving to the pursuits any character less attractive than regulated play, a great degree of intellectual acquisition and improvement may be realised.

The introduction which the child has received in the nursery to the material world, will form a stage in his progress for the more systematic teaching from two to six years of age. *Objects* will still be the *material* of his studies; but they will be so arranged and classed as to conduct him through a complete knowledge of the external features, qualities, and uses—short of their chemical composition—of nearly all the objects with which ordinary life is conversant: simple objects, parts of objects, objects natural and artificial, mineral, vegetable, animal, with their parts, conditions, differences, agreements, manufacture, and abstract qualities, and classification of objects by resemblances and differences. In these exercises several hundred useful ideas may be imparted; all of them made real by the connection of each with some material type.

Simultaneously and incidentally, the words expressing the objects and their qualities, &c. will be given, and, in connection with the object, will never be forgotten. Incidentally, too, the word will be exhibited printed, and so read as well as pronounced, and likewise spelled. The letters of the alphabet will be separately taught as objects. This learning of things and words together will be found beneficial as to both. When the senses are explained, which we assume has been done, the exercise will be easy and improving which connects the objects with each sense, or with several at a time; in other words, whether the pupil has seen, heard, touched, smelled, tasted, or weighed the object or its quality. Thus without a task, almost insensibly, and as it were at play, the child in four years will have attained a sum of knowledge of great extent and value, which will form the basis of an enlarged mind in after-life, and prepare for the future acquisitions of science and philosophy. The rule should be rigidly observed, that no object in nature or art should ever be spoken of to a child without an endeavour being made to present it to him either in reality, model, or drawing, and this practice should be continued till the object has become familiar to him.

Between two and six, besides the acquisition of knowledge of objects, much elementary knowledge may be gradually, easily, and almost insensibly, imparted: the simpler geography—arithmetic by means of Wilderspin's ball-frame, or *arithmeticon*—the pence-table—weights and measures—letters, syllables, words, lessons on pictures, of animals, &c.—lessons on maxims moral and prudential—anecdotes and stories with a moral and improving tendency, told elliptically—that is, by words being left out for the children to supply, &c. At this age the vocal powers and musical ear should be exercised, which is both amusing and instructive to the children; many of the lessons may be sung. Much knowledge of common and useful things connected with life and manners may be communicated at this age

with an impression that will never be effaced. Lessons, too, connected with exercise in the practice, may be given on the benefits of cleanliness, ventilation, temperance, with all the evil effects of their contraries; while prejudices, fallacies, tyrannies, cruelties, unfairnesses, selfishnesses, bad habits, &c. all of which operate so mischievously on society, may be met by anticipation in lessons and counter-practice, so as to be avoided in after-life. It is plain that the moral and intellectual training must proceed hand in hand. (2)

FROM SIX TO FOURTEEN YEARS OF AGE.—In a rightly arranged and complete course of elementary intellectual education, it is presumed that the period from two to six years of age has been spent in an Infant School. The effect which such a preparation has in facilitating the subsequent operations of the teacher is so great, that every effort should be made to give children the advantage of it.

From six to fourteen is the period of the elementary schools. This is the time during which children, besides having their moral education carried on efficiently, are to be introduced to those branches of instruction which are necessary for the business of life—a process which includes within itself the exercise and development of the intellectual faculties, and the formation of habits of intellectual application and taste.

The two great questions are, what is to be taught? and how are we to teach it? Mother tongue—the power of reading it, acquaintance with its grammatical structure, and with the exact meanings of its words, and the power of composing it with fluency and elegance—is certainly entitled to the first attention. There are three modes of teaching it:—*First*, the old practice of instructing children in it by rote, without regarding whether they ever thoroughly comprehend a single syllable of it, or are ultimately able to make the least use of it. *Second*, what is called the Explanatory Method, now uniformly practised in all well-conducted seminaries, whereby it is at least secured that the pupils have some synonyme for every term that comes under their notice, so as to give some reason to believe that they understand it. *Third*, the Exhibitory Method, which adds to other expedients that of showing, in all possible cases, the objects referred to in lessons, or at least presenting drawings of them on a black board or otherwise. Considering how little the young are prepared for the abstract, and how eagerly, under a natural impulse, they grasp at the tangible, we need scarcely remark that the last method appears to us as one of which advantage should be taken as far as possible.

The first step may be a regular series of lessons on the consonants, single and compound, as they occur both at the beginnings and ends of words. In the selection of monosyllabic words for this purpose, care should be taken, for obvious reasons, to avoid such as refer to coarse and mean ideas. The powers of single vowels being thus also taught, it will be proper next to advance to words in which double vowels or digraphs are exemplified; and so on, as in the work here referred to. (3) The lessons for practice should consist of sentences of such a nature as to admit of amusing explanation and illustration by sketches on the black board, and by sensible objects.

1. *Names of things* will perhaps be best explained by showing the object itself, or its picture, and by asking the children to tell what they know about the object. Their own simple definitions are very often the best.

2. *Names of qualities* may be taught by requesting children to name objects that have the quality. For example, to explain *deep*—'Tell me anything that is deep?' The following have been named.—'The sea, a well, a coal-pit, a canal.'

3. *Names of actions*, by performing the action named, or describing it by some interesting anecdote, so as to show practically the meaning of the word.

These suggestions may by some be considered trifling and childish, but a proper trial is requested, and the result will show whether children make more real im-

prevention by the above simple and obvious expedients, or by being 'crammed' with etymological crudities and dictionary definitions. (4)

Grammar will incidentally accompany the reading, in the form of parsing. By what is called the *incidental method* much advantage is gained: knowledge of an object and its qualities is obtained; its name is pronounced, written down, and read; while its description is read and parsed; all which exercises, instead of impeding, actually aid and facilitate each other. A judicious extension of the incidental method may be made one of the most important means of advancing popular education. Learning to spell orally columns of a book, is a waste of time, and an irksome labour. We spell only when we write; and the power is really not attained by the old school exercise of spelling, but by reading; the words become familiar to the eye as *specific forms*. No one who reads much can remain a bad orthographer; and no one writes much who has not previously read a great deal more.

*Simple Lessons in Reading.*—The child may now make a step forward in the art of reading and spelling, and be prepared for more methodical intellectual culture. At the same time, in order to *assure*, and induce reading for *the pleasure it communicates*, the subjects of the lessons should be of that species of narrative which delights the infant mind, bearing, in each case, a reference to the perceptions of the pupil, or tending to encourage in him a love of the beautiful in nature. Instead of the old unprofitable reading and spelling in schools, the improved plan of instruction in English consists of—*First*, Correct reading, dividing and spelling of words; meaning by spelling not the laborious and useless committal to memory of whole columns of spelled words, but, 1, naming letters singly by their powers, grouping them into syllables, and these again into words, so as to read a language; 2, putting down letters on paper, in proper number, order, &c. so as to produce a combination expressive of sound, and thus *write* a language. Spelling is acquired by constant practice in reading, writing from dictation, copying pieces from good authors, composing and correcting original essays, and performing systematic grammatical exercises. *Second*, Understanding what is read—proved by searching examination, and illustratively aided by real objects. What is called the *elliptical method* is here much used, the child supplying the omitted words, and receiving, according to the skill and information of the teacher, much collateral information. Very simple ideas only ought to be called up, and such matters alluded to as may be supposed to interest and encourage the dawning faculties. We cannot too earnestly recommend the practice of illustration by pictures and sensible objects. The *black board* and chalk should be in constant use, and every teacher should qualify himself to draw ready off-hand sketches. The rudest outline done on the spot excites more interest than the finest engraving. The lessons themselves, in detail, are given in the work here referred to. (5) The curiosity of young persons is necessarily first excited by the things which lie most immediately around them, and the circumstances and procedure of familiar life. These are the subjects of their earliest inquiries, and it is extremely desirable that clear, distinct, and correct explanations of them should be invariably given. Most parents of intelligent and well-regulated minds take care that such should be the nature of the answers given to the first inquiries of children; but it is needless to point out, that many persons who have children under their care, either possess not the ability, or have not the necessary leisure, or will not be at the pains, to give correct and satisfactory answers. Lessons should be given which aim strictly at an explanation of *external appearances* in the natural and social world. *Principles* are for subsequent study. The subjects may be such as the following:—Of God and the works of creation; of animated creatures; of mankind; of the country; processes of husbandry; common inanimate objects; and the more familiar arts. (6)

In elementary education, after some progress has been made in the power of reading, the different conditions of a child at about seven, and at from ten to fourteen years of age, suggest the necessity of *two series* or courses of instruction—one of an elementary or primer-like character, the other more advanced, but both going over nearly the same ground. This is the more necessary, as so many children are taken into school about ten years of age. In the construction of a series of school-books, already more than once quoted, we have proceeded so far upon this arrangement, most of the volumes of the advanced section of the course being foreshadowed in that which may be called its *preliminary*. We observe the same arrangement on the present occasion:—

#### Preliminary.

*Introduction to Geography.*—The pupil having, in the Infant School, had some instruction in the simplest elements of geography, may, in his seventh or eighth year pursue the study more regularly. Lessons may now be given which will suit those whose education allows but a small portion of time for geography—lessons calculated to impress a fair measure of that most useful knowledge even on the future manual labourer. They need not give copious lists of localities, capes, bays, districts, and towns, it being presumed that the learner has maps before him on which he will be exercised. He cannot, moreover, be introduced too early to the *Globe*, for the spherical as well as relative position of its great divisions, with their latitude and longitude. Proportion should also be impressed upon him; this is apt to be confused by maps of different sizes. The relative situation of countries need not be much alluded to, that being best learned on the maps. The chief attention should be devoted to the *character, physical and political, of the countries*. The plan should be followed of treating, generally, in the first place, of the plants, animals, and races of men, in the different regions; and in the second, of the most important particulars peculiar to each country, which cannot be brought under general heads. With the maps and globe always before the pupil, much useful information may by this method be conveyed. (6-30)

*Writing.*—This is entirely an art, to be acquired by practice, with the assistance, first of a skilled teacher, to train to the mode of sitting, of holding the pen, &c.; and second, of suitable exemplars of the various kinds of writing (42-45). A free and bold practice on sand tables or with chalk upon a black board, would probably form a good introduction to the art of calligraphy. It was by such means, under the guidance of his father, that the celebrated Person acquired that accomplishment of singularly elegant writing, for which he was scarcely less remarkable than for his extraordinary attainments in classical literature.

*Introduction to Arithmetic.*—The simplest elements of arithmetic are presumed also to have been taught in the Infant School, by means of the instrument called the *Arithmeticon*. In this early school period it may be pursued by means of regular exercises wrought upon slates, according to the rules presented in an appropriate book. An active teacher may also do much for this part of school education by conducting mental exercises, or exercises in which no sensible figures are used. It is found an excellent discipline for giving habits of attention and concentration. (14)

*Introduction to English Composition.*—The pupil may be at this early period introduced to English composition. We recommend the modern plan of teaching the rules last. Let the pupil successively compose and write down nouns; then their qualities, or adjectives; then the action or change, or verbs. He has been a *composer* from the moment he began as a child to practise. Let him go on, and he will insensibly infer the essential laws of language, by his own experience and his teacher's hints, more rationally and more thoroughly than from a system of grammatical rules, necessarily dry, irksome, and repulsive. In giving these lessons on composition,

the following suggestions will be attended to:—1. It is suggested that, previously to a pupil's entering on composition, he should spend a few weeks in copying, with great accuracy, short pieces in prose from some good author. This will give the habit of neatness and exactness in the use of points, capitals, &c. and if carefully managed, will form an excellent preliminary exercise. 2. Each pupil should be provided with a quantity of common paper for the scroll copy, an exercise-book for transcribing, and this text-book. 3. Let the teacher place fifteen or twenty familiar objects on a table or desk before the class, and request the pupils to comply with the direction in the first lesson, by writing on the spot the names of the articles; and so on with the other lessons, in order. 4. When the lists are finished, they should be exchanged, and each pupil should correct the spelling, &c. of his neighbour's work. 5. This done, the papers may be returned to their owners, for the purpose of their reviewing the criticisms; and all should be encouraged to protest against false corrections. 6. The teacher should then pass round the class, deciding disputed points, explaining the ground of each decision, questioning the pupils, and allowing them freely to question him. 7. The scroll-copy thus corrected should be taken home by its owner, neatly transcribed into the exercise-book, which, duly dated, should be handed to the teacher next day. 8. The teacher may then mark the errors in the transcript, asking the pupils to show the cause of each correction. 9. The exercise-book should then be returned to the owner, with a number (in the teacher's handwriting) indicating the rank of the exercise. 10. At the end of each lesson, the pupils should be questioned on the parts of speech employed, meaning of words, knowledge gained, &c. 11. The pupils should use *black* ink in writing the exercise, and *red* in correcting. The teacher's criticisms, remarks, and numbers should be in *blue* ink. These distinctions, though apparently trifling, will be found important. 12. Three or four lessons may be given weekly, according to circumstances. Less than half an hour will suffice for writing each exercise, and little more than that time will be required for correction. The lessons will proceed from objects to qualities and actions, each embracing a very wide field of exercise. (8) The derivation of words from other languages, technically *ETYMOLOGY*, both simple and compound, may at the same time be an incidental exercise. (11)

*Introduction to the Sciences.*—The pupil has hitherto been conversant with the *external* features of objects, and the ordinary uses to which they are put. At the age of nine or ten he may be gradually introduced to philosophical *principles*—to a connected and systematic view of nature, the most obvious parts of which it is composed, and the laws by which it is governed. The subjects will be—the extent of the material world; the stars, solar system, the earth as a planet, the moon, eclipses, masses of matter—their attractions and motions; the earth—its general superficial features, its structure; the soil, the atmosphere, heat, light, electricity, and magnetism; evaporation, clouds, rain, frost, ice, snow, the winds; elements of matter—their combinations; the vegetable creation; animal creation; man—his general character and history, his bodily nature, his mental nature. (9)

*Rudiments of Music.*—About this stage of education, the pupil may be introduced to the principles and rules of vocal music. This is invariably a branch of education in several continental countries, and is attracting marked attention in Britain. In the Infant School we have already recommended simple singing by the ear; the pupil may now not only study musical rules, but learn to sing from notes.

Advanced.

*Geography.*—A year or two after the pupil has mastered the Geographical Primer, he may proceed to study geography in a more enlarged and generally informing manner. (31–32) Taking England as the first of a

series of countries, he will study its situation, extent, division, and general detail of localities; after which will come its physical geography, including superficial features, climate, soil, and vegetable productions, minerals, animals, natural curiosities; next, its historical geography, including remarkable events, antiquities; its political geography, including its civil state, revenue, army and navy, and ecclesiastical state; its social geography, including its national character, language, literature, arts and sciences, manufactures and commerce. In thus studying the geography of particular countries, a constant reference to maps is necessary. By having these sufficiently large, and the natural features strongly marked, as in the series here referred to (47–48), a whole class can learn at once.

*Arithmetic and Grammar.*—These branches are now pursued on more comprehensive plans, and with a deeper investigation of principles. In connection with the former (15) stands book-keeping (16); with the latter (10) etymology and composition—all of which will now be thoroughly mastered, as technicalities of the greatest importance for the business of life.

*Drawing.*—This is an art, of the same character as writing, less imperatively necessary, but yet entitled to more attention than is generally paid to it. Its elements may be acquired by all, and are calculated to be useful in many circumstances throughout life. These may be taught by the use of chalk upon a black board. The objects should be the simplest delineations of common things, beginning with practice in straight and curved lines, and proceeding to a paling, a wall, a gate, a guide-post, a house, a rustic bridge, utensils, tools, and implements, flowers, patterns, and animals. On the black board, the chalk, compasses, and rule may be employed; on the slate, only the hand and eye should be used at this stage of the young pupil's progress. Deeper lines will show foregrounds—lighter, backgrounds; and thus the first notions may be given of aerial perspective. By rendering universal some instruction in drawing of common objects, real talent, where it exists, will never be concealed; while much pleasure will be derived from efforts far short of those of the higher order of genius. (44)

The pupil will in due time advance to the elements of drawing and perspective, and the art of sketching from nature. (45) Terms in the art of perspective should be explained to him, and figures delineated, which are nothing more than the simpler geometrical diagrams. The sector, visual rays, points of sight, all the rules of perspective, should be plainly and intelligibly laid down. Black-lead pencil-drawing, characters of foliage, light and shade, and tinting; styles and modes of treatment in sketching from nature, both landscape and figures, with the rules for arrangement and effect, should all be made plain to and practised by the pupil, the teacher guiding his efforts. We may remark here, and the observation is of general application, that the teacher must keep in mind that intellectual powers are bestowed on different individuals in different degrees; and such differences must be allowed for. It will soon be seen whether the pupil possesses powerfully the drawing or pictorial faculties. If he does not, he should never be pushed beyond the simplest elements of the art. The same is true of other branches of study.

*Natural or Mechanical Philosophy.*—The pupil, now advancing to his eleventh and twelfth year, may proceed to the elements of mechanical philosophy, by custom, though too extensively, called *natural philosophy* or *physics*; seeing that, under that denomination, chemistry and even natural history have as good a claim to be ranked. It is a question whether this branch of physical science, or chemistry, should be studied first. We think they may, in their elements, proceed together; but if singly, it seems rather more natural to attend to the more visible and tangible properties and powers of matter, unchanged in its substance, than to those that require a change in the constitution of mat-

ter, often its destructive analysis, to ascertain its composition. All should be familiar with the laws of matter and motion—with matter's impenetrability, extension, figure, divisibility, inertia, attraction, cohesion, capillary attraction, chemical attraction, magnetic attraction, gravitation, repulsion, heat, evaporation, contraction, ignition, density, specific gravity, compressibility, elasticity, dilatibility; with motion and forces, weight in falling bodies, centre of gravity, pendulum, centrifugal force, projectiles, action and reaction, motion in elastic bodies, reflected motion, composition of motion and of forces. (23)

*Mechanics and Machinery.*—The pupil, after having attained a competent knowledge of the above particulars, may proceed to study the mechanical powers and their philosophy—the lever, pulley, and inclined plane, which are the primary mechanical powers; while from the lever and inclined plane come the other three, or secondary mechanical powers—the wheel and axle from the lever, and the wedge and the screw from the inclined plane. The combinations of mechanical powers, friction, human labour, horse-power, draught, water-power, and steam-power, and all the science of machinery, will naturally follow. (24)

*Hydrostatics, Hydraulics, and Pneumatics* will next in order engage the pupil's attention; and he should not be suffered to proceed without having mastered, by the test of strict and searching examination, the previous subjects, which form a series.

When he has become familiar with the mechanics of solids, he will proceed to the study of the laws of fluids, including the aeriform fluids. The hydrostatical part embraces pressure of water, levels, specific gravity, fluid support, &c. Under hydraulics—the hydraulic press, aqueducts, fountains, friction between fluids and solids, action of water in rivers, waves, change of temperature, &c.

Under pneumatics are comprised—the atmosphere, laws of air, pressure of air, the air-pump, pressure of air on solids and liquids, on mercury; the barometer, pumps, siphons, steam, latent heat, winds, sea and land breezes, ventilation, diving-bell, buoyant property of aeriform fluids, balloons. (25)

*Optics, Acoustics, Astronomy, Electricity, and Meteorology*, will complete a course of natural philosophy. (26 29 30)

*Chemistry.*—It will now be time to lay a foundation for the pupil's future progress in chemical science, and at the same time impart to him a practical knowledge of the chemical laws and operations which are at work around him in daily life. (31) Such are respiration, combustion, heat, light, water, poisonous gases; these are all matters upon which comfort, health, and life itself may depend. The teacher should begin with showing experiments, and should be possessed of a museum of substances and chemical agents, with an apparatus.

*Animal Physiology.*—The important purpose served by including this subject in juvenile education, is the preservation of health, not its restoration when lost; the prevention of disease, not its cure, with which last the ignorant cannot be trusted. It ought to be impressed as a maxim, that although we ought not to be our own doctors, we need not be our own destroyers. We ourselves can bear testimony to the successful introduction of this study in several schools; and to the interest taken by the pupils of both sexes, from nine to twelve years of age, in the lessons, which are illustrated, as they ought always to be, by diagrams. (32)

*Mental Philosophy.*—This is a department of science which it is the fashion of our age to overlook. Yet what can be more important than a knowledge of that wonderful power by which we think and act, and which more especially connects us with the things above and beyond this humble and transitory scene? No serviceable manual as yet exists for imparting a knowledge of mind in schools; but an intelligent master has it in his power to do much by oral instruction.

*Mathematics.*—This important branch of study can-

not be omitted in elementary education. In its widest sense, it is that science which treats of measurable quantity, in magnitude and in number. *Geometry* is the branch of mathematics which treats of that species of quantity called magnitude, both theoretically and practically. Theoretical geometry investigates the relations and properties of magnitudes in three dimensions—as lines, surfaces, and solids. Although magnitudes have no material existence, they may be represented by diagrams. That branch of geometry which relates to magnitudes described on a plane, is called *Plane Geometry*. This requires six elementary books—a book on the quadrature and rectification of the circle, a book on geometrical maxima and minima, an exposition of the method of geometrical analysis, and an additional second and fifth book. The basis of the first six books should be the 'Elements of Euclid,' as given in the very correct edition by Simson, with the improved fifth book by Playfair, and the other improvements of the latter geometrician contained in his original edition of Euclid's 'Elements.' The pupil will proceed with the definitions, postulates, and axioms. (18) Solid and spherical geometry and conic sections (19) will next engage the pupil; and finally, the elements of algebra. (17)

*Elocution* may be the next pursuit of the pupil. In this branch of study the subjects of articulation, inflection, modulation, and the measure of speech will be familiarly explained. (12)

*History, &c.*—History and biography are important branches of information, of which it is well to acquire the elements at school. The history of the mother country, its literature, and great men, has the most immediate claim upon attention; after which come the histories of the countries to which geographical and political circumstances, or any other cause, have given importance in our estimation. (37-41)

*Natural History.*—As a study for the two last years of the fourteen, ought to be reserved natural history, which is better understood, and more beneficially acquired after than before the study of the elements of chemistry and mechanical philosophy. The pupil, in this branch, will learn to distinguish the animal, vegetable (34), and mineral kingdoms; the atmosphere and its phenomena (30); the winds, the ocean with its tides and currents; the discoveries of geology (35); the nature of animals (33) and plants (34), &c.

*Political Economy.*—A pupil who has entered his fourteenth year, with his mind stored with the knowledge and strengthened by the exercise of the education we have described, should be introduced to the elementary principles of political economy. Society suffers in its vital interests from the prevalence of ignorance and prejudice in this great field of speculation and action.

*Logic.*—The elements of logic appear to us to form the appropriate conclusion to our practical elementary course from six to fourteen. All that precedes it is knowledge, and, as such, chiefly addressed to the *knowing* faculties of the mind. But man has also *reflecting* faculties; and it constitutes the chief end and object of our knowledge to furnish these with materials for their exercise, which is called reasoning. This, the highest operation of mind, is regulated by laws in the nature of things, which right reason both discovers and obeys. These laws systematised constitute the science, practically the art, of logic. The pupil, while he masters its principles, should be well exercised in their application. (See No. 73 of this Series.)

*Religion.*—The first principles of religion are understood to have been imparted under the circumstances indicated in our section on moral education. In a school course, due provision must be made to carry out this all-important department. Looking only to what the principles of education ask from us on this point, we would direct, first, the continuation of the method formerly described; next, daily Scripture reading; next, a subjection of the individual pupils to the agency of the ordinary means of diffusing religious knowledge and maintaining religious impressions.

CHAMBERS'S EDUCATIONAL COURSE.

*Languages.*—Though it is a great error to regard the acquirement of one or two ancient languages, and a school study of a few of the books written in them, as constituting a liberal education, unquestionably a liberal education ought to include that acquirement and that study. The commencement of a classical course, as it is called, may be made during the latter part of the elementary period; but it should mainly be postponed till after fourteen, when the comparative ripeness of the mind enables a pupil to acquire more of this kind of knowledge, and that more effectually, in one year, than in three or four at an earlier stage. The study of the classical languages is a special education, required by those whose occupations are to be of a philosophical or literary character. In an expressly literary education, they would always form a conspicuous element. And the refining effect which the admirable productions of the Grecian and Roman writers is calculated to have upon the minds of all must be at once admitted. The abuse of these languages in education has been solely in their being made the sum and substance of all education, and, though in a less degree, in their being taught at a period of life when it is impossible to experience their softening and improving influence. (CLASSICAL SERIES.)

MECHANISM FOR EDUCATION.

The mechanism for education may be said to be of two kinds—that which is furnished in the family circle, and that which is furnished by public establishments.

The mother is an educator of nature's appointment, and the first. To her falls the duty of securing the sound organisation of the infant, as far as it can be done by obedience to nature's rules before and after his birth. She has the duty of drawing his senses and intellectual faculties into that gentle exercise which gives them vivacity without being attended by danger, and that of establishing the basis of regular and correct moral habits. For all these purposes she is in a position of great influence; for her infant, accustomed to look chiefly and most immediately to her for protection, kindness, and every comfort, is unavoidably disposed to pay to her that veneration on which genuine influence depends. She is, as has been well said, the DEITY of the child, and nothing but a sad misuse of her own feelings can prevent her from being all-powerful over him for the regulation of the whole economy of his being, at least during the first two or three years of his life.

So far as moral education depends, as we have shown, on moral atmosphere, and the influence of immediate example, the importance of home as a part of the mechanism of education must be acknowledged. Before the period of school attendance, home is all in all: thereafter, it still continues to bear a great share in the duty. The formation of moral habits, and the development of religious feelings, will depend much on what is done in these respects in the family circle. Parents may even serve as aids to the business of school, to a degree of which they have in general little conception. First, they may do much in the way of enforcing and providing for that important requisite—regular attendance. Second, they may strengthen the hands of the teacher by paying him a proper respect. Compared with these objects, the mere superintendence of lessons given out to be learned at home, is, though itself important, a trifle. There is a tendency in parents to be over-easy in the admission of excuses for attending school; and they often take away their children for a considerable time, for reasons affecting their own convenience and pleasure. It is also not uncommon for them to look down upon teachers, and speak of them, and even to them, in no very respectful terms. All these are errors of a fatal character, seeing that they weaken the school mechanism in some of its most important requisites.

A child becomes a fit subject for the education of public establishments at from two to three years of age or thereby. From this age till six, he should, if possible, attend an Infant School.

The *Infant School*, although a modern invention, is a part of educational mechanism which is now generally approved of throughout Europe, being in vogue not only in Britain, France, Holland, and Germany, but even in Italy. It is, when rightly constituted, only a nursery upon a large scale—a place where infants may be reared in company instead of being kept in solitude—where they may be reared in pure and well-regulated circumstances, instead of being exposed to the contaminations of a public street. It is peculiarly essential for the children of the poorer classes, who are otherwise so liable to become a mere infantine *canaille*; but it might be well for children of every grade to be brought up in Infant Schools, as society or assembling together is essential to the working out of many of the problems of education.

An Infant School should generally be calculated for about 100, or not more than 140 pupils, of both sexes. Two teachers, male and female (if possible, a man and his wife), are required—the one to superintend the boys, and the other the girls. The school should be well ventilated, and fitted up with a long gallery containing six or seven tiers of seats, and divided into two departments for the various sexes, the younger children being disposed in the lowest forms. The walls should be furnished with drawings of natural and other objects; and a black board and arithmetic ball-frame should likewise be provided. A piece of play-ground is so essential, that no establishment without one is entitled to be considered as an Infant School. It should have flower-borders, which the children are trained to respect, and places of convenience, where cleanly and delicate habits are inculcated. A circular swing is required for the amusement and to promote the physical health of the children; and it will be well to have a quantity of wooden prisms, of the form of bricks, with which they may engage in the building of houses, towers, and other structures, according to fancy.

The intellectual education of an Infant School is limited to the learning of little hymns and knowledge rhymes, the study of simple geometrical forms, and of the merest elements of arithmetic, exercises upon narrative passages of Scripture, the properties of objects, the characters of animals, the names of countries and cities, &c. In some, reading and grammar have been introduced, to satisfy prejudiced parents; but these are departures from the right character of the institution. Most of the lessons are metrical, and sung to simple airs. The moral department, confessedly the chief, consists in the learning of good precepts, Scriptural and otherwise, the fostering of kindly and gentle dispositions, and the restraint of angry and malevolent feelings, the formation of conscientious, truthful, polite, and delicate habits. It is remarkable how far a good Infant-School teacher can accomplish these objects, and how quickly any new pupil is brought into harmony with the general spirit of the place.

An Infant-School teacher requires a union of qualifications which is not often attainable. He should possess a gentle and affectionate character, with unlimited patience, yet have that intellectual activity and vivacity which are necessary for sustaining attention in young children. He must both be a well-informed man and capable of making what he knows readily intelligible to those who know nothing: he must both be firm and discreet in management, and possessed of manners of almost infantine playfulness. A knowledge of music, and a good voice, are amongst the qualifications which he requires.

The elementary schools following upon the infant seminaries (where these exist, or, otherwise, being the first schools) are different in different countries, not only in the materials and modes of instruction, but in the extent to which they carry on pupils. In Britain, they are generally in a state considerably inferior to what is found in Holland and Prussia. In a rightly-constituted system, there would be two seminaries between the Infant School and the university—the first, or primary school, being devoted to those branches of

instruction in which all should participate; and the second, or secondary school, affording continued and more advanced instruction to those destined for professions and for the more important places in society, and, as such, being preparatory to the university. The parish school and grammar school of a small Scottish burgh may be considered as an arrangement approaching to what is required in this respect.

The primary school is applicable to the ages between six and ten or eleven. In a country under a national system of education, one would be required for every group of population above a thousand in number, as the attendance would then probably be from a hundred to a hundred and fifty. Reading, grammar, arithmetic, the elements of geography, history, and science, and moral training, would form the chief features of the business of a primary school. And to this extent all should be educated. It follows that infant and primary schools ought to be special subjects of state provision and care. Society is expressly interested in seeing all children trained and instructed thus far, that they may become a moral and intelligent population. So strongly is this regarded in Prussia, that education, up to the point in question, is enforced by law. Certainly it is at least well to encourage parents, by all means consistent with the spirit of a free country, to have their children educated to this extent. While the state, then, regulates the education of infant and primary schools, the state should also furnish it gratuitously, or all but gratuitously, thus removing all difficulty which may be felt by indigent individuals, the very class whose children are apt to become most dangerous if left uneducated. It has often been objected to the idea of gratuitous education, that what is obtained for nothing is not valued; but the education furnished by the state (or, as an alternative, by local assessment) would not be really gratuitous. Every parent would know that he contributed to the fund by which the school was supported, and that this was much the same thing as paying fees.

In order to insure a supply of well-qualified teachers, as well as for the sake of uniformity of methods, the infant and primary schools would each require distinct normal schools. Teaching is an art. It is one of considerable nicety, requiring both natural and acquired gifts of no ordinary kind. Without a due apprenticeship to it, no man can be expected to satisfy the demands of the modern educationist. There is a large amount of detail, both in the methods of procedure and in the material of instruction, which a candidate for this employment must have thoroughly mastered before he can duly teach. There is also an aptness and facility for the duty which nothing but practice can give. For all of these reasons, schools for the training of teachers, or normal schools [so called from *norma* (Latin), a rule], are indispensable. We have not room here to enter fully into the details of a well-constituted normal school of any kind, but may pause for a moment to indicate the important principle, that it is not sufficient for a young man to sit by, observing the procedure of a well-conducted school; he must enter personally into the business, and be accustomed to act as a teacher himself, in order to attain the qualifications necessary to successful tuition.

We have considered the infant and primary schools as comprehending the education required by all the children of a state, and as therefore calling for state support and regulation. For this reason we have indicated a conclusion to the primary-school period somewhat later than what is practically the case in the schools answering more or less to this description. Generally, the primary school period may be said to end at nine years of age, at which time a boy, for example, is considered as fitted to commence a classical course in a higher school. While the material of intellectual education remains generally as it is, this arrangement will be appropriate; but if we consider some branches of general knowledge as necessary for all, we must postpone the conclusion of the primary period to ten or

eleven. At that age the children of the humbler classes would be fitted to commence the active life to which they are usually destined, while others would be equally ready to go forward into advanced schools.

The secondary school—answering to the grammar schools and academies of Britain, the colleges and *pensions* of France, the gymnasia of Switzerland and the German states—is the first school appropriate chiefly to the middle and upper classes. As its benefits are not universal, it should be supported solely by those who take advantage of its instructions, although the state may extend to it protection and regulation. The higher intelligence required of the middle and upper classes, and the special education required for the professions which many of these classes are called to follow, constitute the necessity for secondary schools. They are introductory to a university course for those who are to follow law, medicine, divinity, or any of those other occupations which are now rising into the same rank with the ‘professions;’ those otherwise destined here obtain that comparatively liberal education which is required in the middle walks of life. The course of instruction proper to a secondary school corresponds with what has been pointed out in the preceding section as the advanced department of intellectual education. It may here be proper to remark that, when we speak of certain classes of the community attending this advanced order of schools, we do not mean that these are to be conducted on exclusive principles. Let their fees be as moderate as possible, and let all who can afford attend. In such circumstances, it would often happen that children of the humbler classes, who showed an aptitude for education, would obtain it, and be thereby enabled to make an advance in life suitable to the faculties with which nature has endowed them.

Religious instruction is presumed, as formerly indicated, to be imparted, throughout the whole period of elementary education, in schools. Here a difficulty as to arrangement unfortunately arises from the various views which are taken on doctrinal points. The teaching of doctrine according to the views of any one denomination, necessarily precludes, from the school where it is done, the children of those who dissent from the views in question. On the other hand, if doctrine be excluded, those who are most eager for the inculcation of particular doctrines or for the maintenance of particular religious institutions, are offended. To obviate the difficulty as far as possible, a particular arrangement has been made in Holland, in the Irish national schools, and some others; Scripture reading is there confined to such parts as include no controverted doctrines, and to a general reference to the Bible on preceptive points, and all else is taught to the pupils, at extra hours, by their particular pastors. It is thus thought possible to inculcate the doctrines of religion as efficiently as by any other plan, while the school is allowed to be a common good to all classes of the community, and a means of bringing up the children of religious parties in harmony together.

INDUSTRIAL EDUCATION.

The mingling of industrial arts with education is an idea of modern times. One of the first examples of it, by which general attention was attracted, originated at Hofwyl in Switzerland, in 1806, under the care of a man of fortune, M. de Fellenberg. Here the object was to teach farming on improved principles, while general education was conducted on an almost incidental plan, at intervals, by the superior of the establishment. Schools of this kind have since been planted in other parts of the continent, and in the United Kingdom. Latterly, industrial education has been extended from agriculture to ordinary handicrafts, and in most instances with gratifying success.

As a specimen of a purely ‘agricultural school,’ we select that of Templemoyle near Londonderry, which appears to be conducted in an efficient manner. Established in 1827 by the North-West of Ireland Agricultural Society, for the purpose of giving young men ‘a

plain English education and a knowledge of the principles and practice of agriculture,’ it contained at the period of our last edition [1842] sixty-six pupils, for each of whom a small payment was made. The superiors were a teaching farmer and a schoolmaster, beneath whom was a matron to superintend the domestic establishment:—

‘At half-past five the pupils rise, arrange their rooms, say their prayers, and, in two divisions, which alternate on different days, are engaged until eight in study or in work; half the pupils are with the farmer, and half under the schoolmaster, except on extraordinary occasions, when the services of all are required for the farm, or the season releases them from their agricultural duties. At eight they breakfast, and are free until nine; work and attend school in alternate divisions, from nine until one. Dine at one, and have recreation until two. From two to six, are at work and in school alternately. From six to seven, sup and have recreation. From seven to nine, prepare the lessons for the next day, have prayers, and retire at nine. On Sundays they attend their respective places of worship, and occupy a part of the remainder of the day in religious reading.

The intellectual instruction consists in spelling, reading, grammar, geography, arithmetic, writing, and book-keeping, with some elementary and practical geometry and trigonometry. The farmer gives lectures also in the evening upon the theory of agriculture. It is intended to introduce [now carried into effect] lectures on botany and agricultural chemistry.

The practice includes all the operations of farming, under the different approved systems; the rearing of cattle, the management of a dairy, and, in general, the incidental as well as the direct occupations of the farmer or agricultural labourer. The head farmer, or agricultural master, is expected to explain the principles of the work in which the pupils are engaged, and to take opportunities for incidental instruction. The operations which he is specially called upon, in the regulations of the committee, to teach, are—ploughing, and the setting of the plough, the use of farming instruments in general, the qualities of stock, and modes of recognising them, the treatment and management of dairy and farming stock, the making and repairing of fences, the rotation of crops, and those best adapted to different varieties of soils, the modes of draining, reclaiming, and improving lands, and the most recent inventions and improvements in agricultural implements. The farmer takes those who are sufficiently advanced in knowledge and age to be benefited thereby, to the fairs or markets, to assist in the sale of the products of the farm and stock.

The pupils are divided, for work, into sections, each of which has its monitor or chief, and consists of eight or ten boys. The head monitor, or superintendent, has the control of them in the absence of the master, and arranges with him the distribution of their time, takes an account of the stock and of the products of the labour, and advises with the master in regard to the farm in such a way as to prepare himself for actual superintendence. This place is occupied by the elder pupils in rotation.

The farm consists of one hundred and thirty-three acres, of which one hundred and twenty-five are arable land. It is worked so as to present examples of the most approved rotation of crops, the fields embraced in the same series of shifts lying adjacent to one another. The whole is drained by underground drains, according to the improved Scottish system, and is well enclosed with different fences as specimens, and trials of the various kinds.\*

Industrial village schools are well exemplified in that of Ealing, about five miles from London, established by a benevolent lady. The principles held in view in establishing this seminary were, that the children should early acquire habits of patient industry; that they should

\* Bache's Report on Education in Europe. Philadelphia. 1838.

be acquainted with the value of labour, and know the connection between it and property; that they should have intelligence, skill, and an acquaintance with the objects by which they are surrounded; that the higher sentiments, the social and moral part of their being, should receive a full development. The industrial occupation is gardening, pursued in a piece of ground connected with the school. 'It is divided,' says Mr Bache in the Report already quoted, 'one portion being reserved for the use of the school, another being subdivided into small gardens for the boys. The pupils work in the first under monitors, and receive a compensation in proportion to the useful results of their labour. The second they hire at fixed rates, and dispose of the produce as they please, always receiving, however, the market price for it from the school, if they choose to dispose of it there. The younger children are not allowed to undertake gardens on their own account, but work for others, or for the establishment. Partnerships are sometimes formed among them for the more advantageous cultivation of larger pieces of ground. An account current with each pupil is kept, in which he is charged with the rent of his ground, and the seeds and plants which he has purchased from the stock, and credited with the produce which he has sold to the school.'

In-door occupations are less desirable in alternation with school instruction than these healthy out-of-door labours, but must have the effect of training to steady and persevering habits, not to speak of the actual skill conferred by them. As an example of a school in which such occupations are pursued, we select that of the Royal Military Asylum at Chelsea, where 600 children of non-commissioned officers are reared. Those above eleven are here taught handicrafts, about four hours a day of three days of the week being thus devoted. 'Rather less than a hundred boys,' we quote the 'Report of the National School Society,' 'work as sailors; fifty each day alternately: about the same number are employed in a similar manner as shoemakers, cap-makers, and in covering and repairing their old school-books; besides which, there are two sets or companies of knitters and of shirt-makers, and others who are engaged as porters, gardeners, in kitchen-work, &c. Everything is done by those who work at the trades except the cutting-out. This branch, requiring more experience, is managed by the old regimental shoemakers, tailors, &c. who, with aged sergeants and corporals, and their wives, manage the concerns of the institution. The system of monitors and teachers to overlook the other boys at work is generally adopted; while, in addition to the various branches of industry mentioned, the school furnishes a company of drummers and fifers, and an excellent band of music; the players necessarily devoting a considerable part of their time to the practice of their instruments.' Though there are some defects, the asylum is allowed to be 'an evidence that a greater degree of progress may be made in reading, writing, and arithmetic, and in other branches of learning, than is attained in the great majority of schools, and yet that the boys may be taught music, gymnastic exercises, and various useful trades; thus improving their health, increasing their means of enjoyment, and promoting their future interests, much more effectually than by the prevailing methods.'\*

Industrial education is practised with marked success in various institutions for the reform of young criminals, as in Parkhurst Penitentiary, Isle of Wight, and the Warwick County Asylum; in several for the refuge of destitute persons, as in that at Hoxton, and the Guernsey Hospital; in various schools for orphan and pauper children under the New Poor-Law Act, of which that at Norwood is a most interesting example; and in those charitable institutions commonly known as Ragged Schools (see p. 183, No.

62), which have been recently opened in many of our populous cities. It is not as an *improvement*, which may or may not be adopted, that industrial education is here to be advocated: it is called for as something *absolutely necessary*, to counteract an inherent tendency of all asylums for the maintenance and education of children to become monastic institutions. The children are kept apart from external nature, from human society, and from many or most of the common operations of life. They come out as helpless nearly as they went in. Industrial education presents itself as almost the only conceivable means of fitting such children for entering the world in anything like the same condition as other children. It is not essential that any one child be made a proficient in any one art; the great end is to make them generally acquainted with the arts of life, and to prepare them by habits of industry for earning their own bread when they grow up. From the attention which the Poor-Law Commissioners are giving to the subject, we have no doubt that in a short time we shall see the whole of the forty-five thousand orphan and pauper children of England educated in this wholesome manner. In the late reports of the commissioners there are some excellent hints thrown out. Different arrangements are recommended for different districts. It is suggested, that in an agricultural district there ought to be a large garden which the children should be taught to cultivate, in order to become acquainted with those duties which they will probably be called to perform when they are sent out into the world. They should also be taught to erect sheds or outhouses, to make wheelbarrows and other simple utensils, and to fashion desks and forms for the school. Thus, as farm-servants, they will be able to execute a number of little jobs in carpentry which would otherwise require the interference of the proper tradesman. To enable them to contribute to their own personal comfort and that of their household, without an expenditure of their earnings, they should be taught to make and mend their own clothes and shoes, to plait straw-hats, to make straw mattresses, and whitewash walls. In a manufacturing district the employments should bear a similar relation to the trades of the neighbourhood; and in or near a seaport, the arts connected with maritime life should be taught. Such, in brief, are the views of the commissioners respecting the boys: they recommend that the girls should be trained to the household duties of cooking, cleaning, and washing clothes, sewing and knitting, by having to perform those duties as far as required in the workhouse. It is worthy of remark, that in the Marylebone charity for girls, this plan has been for many years acted upon with excellent results. There the girls are accustomed to make their own beds, to clean their own knives, forks, and shoes, and to be scrupulously clean in their dress. 'Their chief employment' ('Journal of Education,' i. 287) 'is needle-work; but they are employed in rotation to scour the school-rooms, the play-rooms, and the washing-rooms, the tables, forms, and stairs, as well as to prepare and remove the meals of the rest of the scholars, and to wait upon the domestic superintendent and officers.'

The reporter of these circumstances adds, and we fully concur in his sentiments:—'The value of charities of this description is too obvious to require particular comment. By establishing *good habits*, they doubtless accomplish more than can ever be effected by mere precept; and they not only tend to make useful servants, but provident, neat, and intelligent wives and mothers. If it were possible to engraft some part of such a system on the national and other schools, these advantages would become generally diffused, and the consequence would be a great increase in the comfort of the houses of the poor, and an accompanying contentment, productive of the best results on the character, among young married men of the working-classes, whom the extravagance or mismanagement of untidy and ignorant partners often drives to alehouses, and other resorts of idleness and dissipation.'

\* Some Account of the Royal Military Asylum, Chelsea. Second Publication of the Central Society of Education. P. 120.

# ENGLISH GRAMMAR.

GRAMMAR (from the Greek word *gramma*, a letter) is, in its broadest sense, that branch of knowledge which refers to the component parts of language.

The purpose of language is to express our ideas. Similar classes of ideas necessarily arise in the minds of every portion of the human family; for the mind is everywhere the same, in kind if not in degree, and the circumstances and desires of mankind are everywhere less or more alike. To express these classes of ideas, men, in all countries and in all stages of society, use corresponding classes of words, although the words may themselves be different. For example, men everywhere see tangible objects around them. To these they apply distinct *names* or *appellations*, which form, it may be said, one class of words—**NOUNS**. They see things perform *acts*; as, for instance, they see cattle *browse* and kids *dance*. Thus arises another class of words—**VERBS**. They see *white* cattle and *black* cattle; hence **ADJECTIVES**. These and other kinds of words, or, to use the common phrase, *parts of speech*, are found equally in the language of the North American Indian and in the refined discourse of the European philosopher. To exhibit the nature and power of words, taken singly and in combination, viewed as a vehicle of thought or a medium of communication, is the first and highest object of the science of grammar.

In the speech of every nation there are also many peculiarities, both in the formation of words to express varieties of sense, and in the way in which words are arranged, these being partly the result of intellectual peculiarities of the people, and partly the effect of accident. Grammar also takes cognisance of such peculiarities. Hence there is not only universal grammar, which relates to whatever is common to the structure of all language, but likewise a grammar for each particular tongue; as, for instance, the Greek grammar, the Latin grammar, the French and the English grammars. Our present business is with English grammar, or to set forth, as well as we can, within small compass, the structure and the usages of the English language.

There are four parts in English, as in other grammars, *Orthography, Etymology, Syntax, and Prosody*.

**ORTHOGRAPHY**, from the Greek words *orthos*, right, and *graphé*, a writing, is that part of grammar which teaches the nature and powers of letters, and the proper method of spelling words.

**PROSODY**, from the Greek word *prosodia*, the accent of a word, treats of the pronunciation of words, and of the laws of rhythm or versification.

On both these departments we mean to say nothing, principally because, as we apprehend, they can only be effectually taught by the living voice; besides, as far as relates to Orthography, so few general rules have been ascertained, that they afford little help to the young or inexperienced student. Practice alone can give facility and correctness in spelling. With regard to Prosody, we may further remark, that it relates to a mere luxury of language; because, to the effectual communication of thought, metrical arrangement of language is by no means necessary, and in an elementary work on grammar, it may, without impropriety, be omitted.

This leaves us Etymology and Syntax, which undeniably constitute the chief parts of grammar; and of these we shall treat as fully as our limits permit.

In **ETYMOLOGY** we shall be guided by this principle, which we hold to be established, that every word has of itself a distinct office to perform; and we shall endeavour to exhibit clearly the force and significance of words taken singly.

In **SYNTAX** we shall not attempt to lay down *rules*, as they are called, for every mode of expression, but

rather to exhibit a few of the leading principles of our language, the complete understanding of which will supersede the necessity of minute observations on our part, as it will enable the student to make them for himself. We cannot approve of the exhaustive system of teaching Syntax—framing a rule for every peculiarity that the language contains; much better is it to conduct the student at once to the *principles*, which are, as it were, the fountain-heads of *rules*. In the one way, we should but exhibit to him everything *by our torchlight*; but, in the other, *we kindle his own*, and having pointed out the road in which he is to travel, leave him to himself. When the student is familiar with the principles, it may be desirable to exercise himself on minute details, and a school grammar (see list of school books in the preceding number on **EDUCATION**) should provide exercises on the minutest peculiarities of the language.

## ETYMOLOGY.

**ETYMOLOGY**, from the two Greek words, *etimon*, the root of a word, and *logos*, a discourse, is that part of grammar which treats of the various classes into which words are arranged, of the different modifications they undergo to express difference of meaning, and of their origin and history.

### I. CLASSIFICATION.

Words are the symbols of ideas, and they are classified and named, not from their form, but from the nature of the idea which they represent or for which they stand. The class of any particular word is only to be ascertained by observing the office which it performs. What it *does*, alone indicates what it is.

It would be quite impossible to say, previous to actual inspection, how many sorts of words, or, as they are generally called, *parts of speech*, exist in any language; but upon examination, it is ascertained that all words used in the English language may be arranged under eight heads or classes.

These eight parts of speech are—Noun, Adjective, Pronoun, Verb, Adverb, Preposition, Conjunction, and Interjection.

A definition of each of these classes of words ought to point out the characteristic or specific idea by which it is distinguished from all the others; and every individual word, brought under any of the eight heads, must agree with the definition, *if it is adequate*—that is, neither too extensive nor too limited.

#### The Noun.

A **NOUN**, from the Latin word *nomen*, a name, is the name of any person, place, thing, quality, or principle; or, more generally, it is the name of whatever can be an object of contemplation or subject of discourse.

The characteristic of the noun is this: it gives of itself a distinct idea or object of thought; thus of the words, *to, pen, just, alas! he, terrify, and ship*, the only ones that present a picture to the 'mind's eye' are *pen* and *ship*. These, therefore, we call *nouns*; but the others do not belong to this class.

It should be carefully observed that every proposition, or sentence that asserts anything, must contain at least a noun and a verb—the noun to express the thing spoken about, and the verb to indicate what is affirmed concerning it.

Grammarians usually divide nouns into two great classes—*Proper* and *Common*.

Proper Nouns are such as are applied to individual persons or things only; such as, *Victoria, Britain, Edinburgh, Pyrenees, Jupiter*.

Common Nouns are applicable to whole classes of persons or objects; as, *queen, island, city*. Common Nouns are by some divided into three sub-classes, called *Abstract, Collective, and Verbal*; by which arrangement the class of Common Nouns, in the limited acceptation of the term, includes only the names of things obvious to some of the five senses.

An Abstract Noun is the name of a quality thought of apart from all consideration of the substance in which the quality resides. The term bears reference to an act of the mind, called *abstraction*, by which we fix our attention on one property of an object, leaving the others out of view. Snow, chalk, and writing-paper are white, and from this quality are oppressive to the eyes. Abstracting the quality from the substance, we say, 'Whiteness is oppressive to the eyes.' *Whiteness* thus becomes an abstract noun.\* An abstract noun may also be a name indicating the want of a quality, as *unworthiness*. Comprehensively, abstract nouns are the names of *immaterial existences, acts, or states*.

Collective Nouns are those which, though singular in form, may suggest the idea of plurality. They are such as, *army, clergy, crowd, class*.

The imperfect participle of a verb (which will be treated of afterwards), when used as the name of an action, is called a Verbal Noun. For example, in the sentence, 'The eye is not satisfied with seeing, nor the ear filled with hearing,' the words *seeing* and *hearing* are termed Verbal Nouns.

The Adjective.

An ADJECTIVE is a word that qualifies a noun—that is, marks it out from other things that bear the same name.

The characteristic of the adjective is, that it limits the application of the noun: thus the term *island* is applicable to every portion of land surrounded by water; but if the adjective *fertile* be affixed to it, all islands not distinguished by the property of fertility are excluded from our consideration.

This part of speech seems to have received its name from an accidental circumstance, and not from anything essential to its nature. In the Latin language it was usual to place the word modifying the noun after it, thus *tabula longa*, while we prefix it, and say *a long table*; the Latin grammarians, therefore, called this class of words *adjectives*, from *ad*, to, and *jectus*, thrown, and we retain the term, although our modifying word goes first. If the student has learned to recognise the noun, he will feel no difficulty in knowing the adjective, because its office is to point out some peculiarity or quality which distinguishes the noun.

'Nouns adjective,' says Adam Smith, 'are the words which express quality considered as qualifying, or, as the schoolmen say, in concrete with some particular subject. Thus the word *green* expresses a certain quality considered as qualifying, or as in concrete with the particular subject to which it is applied. Words of this kind, it is evident, may serve to distinguish particular objects from others comprehended under the same general appellation. The words *green tree*, for example, might serve to distinguish a particular tree from others that were withered or blasted.'

Adjectives are generally divided into two great classes—Attributive and Numeral, or those which denote quality and those which refer to number.

The words *a* or *an* (two different forms of the same word) and *the*, are reckoned by some grammarians a separate part of speech, and receive the common name of *Article*—*a* or *an* being called the *indefinite*, and *the*,

\* Though we thus distinguish one class of nouns—those, namely, which come from adjectives or are closely connected with them—by the title *abstract*, we are far from wishing it to be inferred that *common nouns* are not apprehended by the same faculty. On the contrary, metaphysical propriety compels us to admit that such is the case; and if any of our readers feel an interest in the question, we request him, before condemning our opinion, to peruse the third chapter of the third book of Locke's 'Essay Concerning Human Understanding,' and also Adam Smith's 'Dissertation on the Formation of Languages.'

the *definite* article; but as they in all respects come under the definition of the adjective here given, it is unnecessary as well as improper to rank them as a class by themselves.

In signification, *a* or *an* is equivalent to the numeral adjective *one*, and *the* to the demonstrative adjective *that*; and the only difference between them is, that *a*, *an*, and *the*, convey the idea less emphatically than *one* and *that*. Whoever reads Dr Crombie's remarks on the 'Article' must be convinced of the absurdity of reckoning it a distinct part of speech.

Various other words, generally arranged under the head of *Pronoun*, seem more properly to belong to the adjective. For instance, the eight words, *my, thy, his, her, its, our, your, their*, correspond exactly in office with the definition of the adjective; but as they are derived from, and answer to, the *personal pronouns*, they may be called *pronominal adjectives* with more propriety than *possessive pronouns*. If they ever stand alone, they do not exactly supply the place of a noun, but merely have it understood, and so, as will presently appear, do not come under the definition of *pronoun*. In like manner, the words *this* and *that*, with their plurals *these* and *those*, by many called *demonstrative pronouns*; as also the four words *each, every, either, and neither*, named *distributive pronouns*—must in strict propriety be considered as adjectives, inasmuch as they both precede and designate nouns, but never supply their place.

The Pronoun.

A PRONOUN, as its composition indicates, is a word that supplies the place of a noun.

Pronouns may be divided into three classes—*Personal, Relative, and Interrogative*.

The Personal Pronouns are three in number—namely, *I, thou*; and *he, she*, or *it*.

*I* is used when the person speaking refers to himself; *thou*, when he refers to the person addressed; and *he, she*, or *it*, when he speaks of some other person or thing.

In Mr Mill's 'Analysis of the Human Mind,' a work equally interesting to the grammarian and the philosopher, we find the following account of the Personal Pronouns, and we confidently recommend it to the attention of our readers:—'In all speech there is a *speaker*; there is some *person spoken to*; and there is some *person or thing spoken of*. These objects constitute three classes, marks of which are perpetually required. Any artifice, therefore, to abridge the use of marks of such frequent recurrence, was highly to be desired. One expedient offered itself obviously, as likely to prove of the highest utility. *Speakers* constituted one class, with numerous names; *persons spoken to*, a second class; *persons and things spoken of*, a third. A *generical* name might be invented for each class—a name which would include all of a class, and which singly might be used as the substitute of many. For this end were the personal pronouns invented, and such is their character and office. "I" is the generical mark which includes all marks of the class *speakers*; "thou" is a generical mark which includes all marks of the class *persons spoken to*; "he," "she," "it," are marks which include all marks of the class *persons or things spoken of*.'

All pronouns refer to some noun, which, as it generally goes before, gets the name of *antecedent*; but as it may come after, *correlatives* would appear a better term. In the case of one class of pronouns, the reference is so obvious and immediate, that they have been called *Relative*, by way of distinction. These are, *who, which, that, and as*. *Who* is used when the reference is to a person; *which*, when it is to a thing; *that* and *as* refer either to persons or to things.

The Interrogative Pronouns, so called because they are used to ask questions, are *who, which, what, and whether*. When *what* is not used to ask a question, it gets the name of Compound Relative Pronoun, as it includes in itself the ideas of both correlative and relative; thus, 'Give me *what* is in your hand' is equivalent to 'Give me *the thing which* is in your hand.'

The inseparable word *self*, with its plural *selves*, is called the Reciprocal Pronoun, and denotes that the object and agent of the verb are the same.

*Self* is added to personal pronouns for the same purpose that *own* is affixed to pronominal adjectives; that is, to express emphasis or opposition. Thus, 'I did it with my own hand;' that is, without the assistance of any other person: 'He did it all *himself*;' that is, without any help from another.

The Verb.

A VERB is a word that *affirms* something of a noun. The characteristic of the verb is affirmation; it may indeed, in common with the adjective, denote a *quality*; but this is accidental, and not essential to its nature. The *attribute* and the *assertion* are often conjoined in one word, as in the sentence, 'The man *rejoices*;' but they may be separated, and then an adjective will denote the attribute and a verb will indicate the assertion; thus, 'The man *is joyful*.' It is but fair to add, that this doctrine of the verb is not universally received; although, after weighing the adverse arguments of Horne Tooke and Mr Mill, we are inclined to consider it well-founded.

On attending carefully to the nature of the idea presented by verbs, we find that, while they all *assert*, they differ in this respect, that some of them express a sort of action which affects or operates upon some person or thing different from the agent, and that others either denote no action at all, or else a sort of action which is limited to the actor. The first class is called Transitive, and the second Intransitive Verbs. If the student consider with attention the state of his own mind when he repeats, with intelligence, the sentences, 'James *strikes* the table,' and 'James *walks*,' he will have no difficulty in discerning the distinction that exists between a Transitive and an Intransitive Verb.

We have already stated, but the importance of the remark will justify its repetition, that as the noun denotes the thing spoken about, so the verb indicates what we affirm concerning it. Without affirmation there could be no communication of sentiment; hence the class of words by which affirmation is made has been dignified by the appellation of *VERB*, or the word. 'Verbs,' remarks Adam Smith, 'must necessarily have been coeval with the very first attempts towards the formation of language. No affirmation can be expressed without the assistance of some verb. We never speak but in order to express our opinion that something either is or is not. But the word denoting this event, or this matter of fact, which is the subject of our affirmation, must always be a verb.'

The Adverb.

AN ADVERB is a word that qualifies a verb, adjective, or another adverb.

As a *description* of a fact in grammar, this is unobjectionable; but it cannot be received as a *definition*, since the word defined is made use of in the definition. Its application may be thus explained. If we wish to modify the noun or *subject* of a sentence, we must use an adjective; but if the *predicate* is to be modified, or any additional modification to be put on a word already qualifying it, the word then used must be an adverb: thus, in the sentence, 'The sun *shines*,' we have a simple subject, 'sun,' and a simple predicate, 'shines.' If we wish to express any quality of the subject, we must use an adjective; and if the predicate is to be modified, we must bring in an adverb: thus, 'The *countess* sun shines,' and 'The sun shines *equally* on all.'

Adverbs may be divided into four great classes:—

1. Adverbs of *Manner*; as, well, ill, justly, wisely.
2. Adverbs of *Time*; as, now, then, soon, when.
3. Adverbs of *Place*; as, here, hence, there, where.
4. Adverbs of *Quantity*; as, much, considerably.

The adverb, it may be observed, is an abbreviated mode of expression, and the idea could in all cases be conveyed by the use of two or more words. They have a close affinity to adjectives, not only in English, but

in most other tongues. Ruddiman justly says, 'That adverbs seem originally to have been contrived to express compendiously in one word what must otherwise have required two or more.' The truth of this doctrine will appear by an inspection of the following table of Adverbs of Place:—

This place,	Here	To,	From.
That place,	There	Hither	Hence
What place,	Where	Thither	Thence
		Whither	Whence.

The Preposition.

A PREPOSITION is a word that connects two words together, in such a manner as to indicate the relation which the things or ideas signified by them bear to each other.

This part of speech, like the adjective, which it resembles in other respects, has received its name from an accidental circumstance. It generally goes immediately *before* the object related to the other thing named; but the essence of the preposition, it should be carefully observed, is to signify *relative position*.

We subjoin a list of the prepositions in most common use, and we recommend the student to exercise himself in putting them all, one after the other, into sentences. In this way he will learn to apprehend their real significancy; and instead of calling a word a preposition, because it is so named in a compendium of grammar, he will recognise it from its function. Doubtless, by committing the list to memory, a practice as common as it is mischievous, he might soon be able to parse; but his knowledge would be mere deception, and he himself would be but 'as sounding brass and a tinkling cymbal.'

LIST OF PREPOSITIONS.

Above	Between	In	Till
About	Between	Into	Until
After	Beyond	Near	To
Against	Before	Nigh	Unto
Among	Behind	Of	Toward
Amongst	Beneath	Off	Towards
Amid	Below	Over	Under
Amidst	Beside	On	Underneath
Around	By	Upon	Up
Round	Down	Since	With
At	For	Through	Within
	From	Throughout	Without.

The following remarks on this part of speech by Adam Smith, and his scarcely less illustrious disciple, Mr Mill, will amply repay an attentive examination:— 'Prepositions are the words which express relation considered in concrete with the correlative object. Thus, the prepositions *of, so, for, with, by, above, below, &c.* denote some relation subsisting between the objects expressed by the words between which the prepositions are placed; and they denote that this relation is considered in concrete with the correlative object. Words of this kind serve to distinguish particular objects from others of the same species, when those particular objects cannot be so properly marked out by any peculiar qualities of their own. When we say "The green tree of the meadow," for example, we distinguish a particular tree, not only by the quality which belongs to it, but by the relation which it stands in to another object.' And again, 'Every preposition denotes some relation considered in concrete with the correlative object. The preposition *above*, for example, denotes the relation of superiority—not in abstract, as it is expressed by the word *superiority*, but in concrete with some correlative object. In this phrase, for example, "The tree above the cave," the word *above* expresses a certain relation between the *tree* and the *cave*, and it expresses this relation in concrete with the correlative object, *the cave*. A preposition always requires, in order to complete the sense, some other word to come after it, as may be observed in this particular instance.'

To the same purpose Mill says—'It is easy to see in what manner prepositions are employed to abridge the process of discourse. They render us the same service which, we have seen, is rendered by adjectives, in afford-

ing the means of naming minor classes, taken out of larger, with a great economy of names. \* \* \* Prepositions always stand before some word of the class called by grammarians nouns substantive. And these nouns substantive they connect with other nouns substantive, with adjectives, or with verbs.'

The Conjunction.

A CONJUNCTION, as its name imports, is a word used to join words and propositions together.

Conjunctions are of two sorts, *Copulative* and *Disjunctive*. The Copulative not only join the words, but indicate that the things are to be united; while it is the office of the Disjunctive to unite the words, but keep separate the things. The youngest child cannot fail to perceive the difference between these two sentences: 'Will you have an apple *and* an orange?' and 'Will you have an apple *or* an orange?' In the first case, he is to get both things—we therefore use a copulative conjunction: in the second, he is to have one only—we therefore use a disjunctive conjunction.

In one respect the preposition and conjunction agree—they both connect words; but each class does something not done by the other. The preposition indicates the nature of the connection, which the conjunction does not; and on the other hand, the conjunction can connect not merely single words, but clauses or sentences. If I say, 'Give me a knife *and* the book,' you may present the objects named separately or together—the knife being *under* the book, *in* the book, or *on* it, and in each case my request will have been complied with; but if I say, 'Give me a knife *in* the book,' the *relative position* of the objects is fixed, and there is only one way of complying with my demand.

We have asserted that the conjunction couples individual words as well as propositions; but as in this we go against authorities so respectable as Ruddiman, Harris, and Mill, we must take some pains to make good our position. Ruddiman says, 'A conjunction is an indeclinable word, that joins sentences together, and thereby shows their dependence upon one another;' and in a note to his rule of syntax—'Conjunctions couple like cases and moods'—he tells us, that 'the reason of this construction is, because the words so coupled depend all upon the same word, which is expressed to one of them, and understood to the other.' To much the same purpose Mr Mill says—'The conjunctions are distinguished from the prepositions by connecting predications, while the prepositions connect only words. There are seeming exceptions, however, to this description, the nature of which ought to be understood. They are all of one kind; they all belong to those cases of predication in which either the subject or predicate consists of enumerated particulars, and in which the conjunction is employed to mark the enumeration. Thus we say, "Four and four, and two, are ten." Here the subject of the predication consists of three enumerated particulars, and the conjunction *seems* to connect words and not predications.' We do not think that Mr Mill's argument is conclusive. There is no *seeming* about the matter. We wish it, however, to be distinctly understood that we do not charge his doctrine with being altogether erroneous; it is only not complete. It is right, so far as it goes; what we maintain is, that it is too limited.

Ruddiman is correct in maintaining that in the example, 'Honour thy father and thy mother,' the word 'honour' is again understood before mother; but this will not do in every case. The sentence, 'Charles and John rode to town,' may certainly be resolved into two clauses, 'Charles rode to town,' and 'John rode to town.' But can the sentence, 'Charles and John carried fifty pounds,' be resolved into the two, 'Charles carried fifty pounds,' and 'John carried fifty pounds?' Obviously not. The conjunction *and*, in that case, connects the two words 'Charles' and 'John,' and shows that conjointly they are the *subject* of the *predicate* 'carried.' In like manner, in the sentence, 'The man of piety and virtue secures the favour of

God,' it is not implied that 'the man of piety' secures the favour of God, and that 'the man of virtue' secures the same; but that the man uniting the two qualities, the *marks* of which are united by the conjunction *and* secures it. Mr Mill himself, indeed, would appear to have felt quite satisfied as to the conclusiveness of the mode of reasoning which we have been animadverting on, for he immediately shifts his ground, and says that, because in such a sentence as, 'His bag was full of hares, and pheasants, and partridges,' we may substitute the preposition *with*, and read, 'His bag was full of hares, with pheasants, with partridges,' the word *and* is properly to be considered a preposition. To this extraordinary specimen of reasoning it is sufficient to say, that by a similar process we might conclude to use a homely illustration brought forward by Dugald Stewart on a like occasion, that because people are 'supply the want of forks by their fingers, that therefore a finger and a fork are the same thing.' On the whole, we consider that nothing can well be clearer than that these great grammarians have taken up a wrong position; but perhaps we have said as much already as the importance of the subject warrants.

The Interjection.

AN INTERJECTION is a word used to express any sudden emotion or excitement of mind.

Pure interjections are mere instinctive emissions of the voice, few in number, and unimportant in character; and, as to other parts of speech used *interjectively*, the expression is, we apprehend, elliptical; but this circumstance cannot properly change the nature and character of a word. Horne Tooke considers that 'interjections have no more claim to be called parts of speech than the neighing of a horse or the lowing of a cow;' but as there are words in the language which express mental emotion, and nothing else, we must have a name for them, and it would be difficult to find a better than the one in universal use.

PARSING.

The student should now be able to analyse, or *parse*, as it is generally called by English grammarians, any sentence submitted to him. Various artificial rules have been devised to enable one to know what part of speech any word belongs to; but these we mean not to mention, being fully persuaded that such *helps* are altogether 'from the purpose' of grammar, inasmuch as they render thought first unnecessary, and then impossible. No person can parse a sentence which he does not understand, and when he does so understand it, he can have no difficulty in referring each individual word to the class to which it belongs. All he has to do is to compare the idea suggested in his mind by the word to be parsed with the definitions of the various classes with which he must be familiar; and by this mental effort it will soon be ascertained to what class the word belongs. The idea suggested by any word, and the characteristic idea of a class, being brought before the mind at the same time, their identity or difference must be at once apparent. But not to deal in general reasoning more, we shall present the *analysis* of a short sentence by way of example:—

'A man that is young in years may be old in hours, if he has lost no time; but that happeneth rarely.'—*Bacon's Essays*.

*A* is an adjective, because it limits the signification of the noun *man*.

*Man* is a noun, because it is the name of a class of beings.

*That* is a relative pronoun; its correlative is *man*.

*Is* is a verb, because it asserts something (existence).

*Young* is an adjective, qualifying the noun *man* understood. Every adjective must have a noun understood if not expressed.

*In* is a preposition, inasmuch as it points out the *relation* that 'years' has to 'young man.'

\* It must be confessed that it is not in all cases easy for the mind to apprehend the nature of the relation pointed out by a preposition. The student will do well to familiarise his mind with *physical relations* in the first place, and moral will after-

*Years* is a noun, being the name of a portion of time.  
*May* is a verb, asserting something (power) of the noun *man*.  
*Be* is a verb, asserting or denoting existence.  
*Old* is an adjective, qualifying the noun *man* understood.  
*In* is a preposition, as above.  
*Hours* is a noun, being the name of a division of time.  
*If* is a conjunction, connecting the clause, 'A man that is young in years may be old in hours,' to the following clause, 'he has lost no time.' As *if* in such cases points out the condition on which the assertion going before it is to be received, it is called by many grammarians a conditional conjunction.  
*He* is a personal pronoun, standing instead of the noun *man*.  
*Has* is a verb, asserting something (possession).  
*Lost* is a verb indicating an act. On the nature of this part of the verb we shall have more to say afterwards.  
*No* is an adjective, qualifying the noun *time*.

*But* is a conjunction. It connects the two clauses, and at the same time indicates, or, to adopt the apt expression of which Mr Mill frequently makes use, *connects* that the clause coming after it is in opposition to the one going before, and therefore it is called a disjunctive conjunction.

*That* is a demonstrative adjective, qualifying the noun *thing* understood.

*Happeneth* is a verb, asserting something of its subject, 'that thing.'

*Barely* is an adverb of time, modifying the verb *happeneth*.

As an additional exercise in *parising*, we shall transcribe a stanza from Campbell's beautiful ode, 'Farewell to Love,' containing, according to our view, ten of each of the three classes, nouns, adjectives, and verbs; five of the two, pronouns and prepositions; two conjunctions, and three adverbs. The student is requested to make a careful analysis for himself, and see how far our enumeration be consistent with his own:—

'Hail! welcome tide of life, when no tumultuous billows roll;  
 How wondrous to myself appears this halcyon calm of soul!  
 The wearied bird blown o'er the deep would sooner quit its shore,  
 Than I would cross the gulf again that time has brought me o'er.'

To the subject of *parising* we shall return before we quit Etymology; but for the present we wish to direct the attention of the reader to the various modifications put on words to express a difference of meaning.

II. INFLECTION.

Any change made upon the termination of a word is called its *accident* or *inflection*; thus, the words, *boy's*, *harder*, *its*, *loved*, and *sooner*, are said to be inflected forms, or simply inflections of the words *boy*, *hard*, *it*, *love*, and *soon*. Of the eight parts of speech, five only—the noun, adjective, pronoun, verb, and adverb—are declinable—that is, capable of being inflected; while the remaining three—preposition, conjunction, and interjection—are indeclinable—that is, cannot be varied in such a way as to express any modification in meaning.

Inflection of Nouns.

The noun is varied in three ways—by Number, Gender, and Case.

Number shows whether one or more than one thing is meant by the noun.

There are two Numbers, the Singular and the Plural. The singular expresses one of a class; as *river*, *horse*. The plural denotes more than one; as *rivers*, *horses*. The plural is generally formed from the singular, by adding the letter *s*; thus, *table*, *tables*; *book*, *books*.

Nouns ending in any of the five following terminations, *s*, *sh*, *ch* (when pronounced soft), *x*, and *o* (*impure*—that is, preceded by a consonant), form their plural by adding *es* to the singular; thus, *brush*, *brushes*; *church*, *churches*; *box*, *boxes*; *hero*, *heroes*.

When *ch* is pronounced hard, and when *o* is preceded by a vowel, the plural is formed by adding *s*; thus, *monarch*, *monarchs*; *folio*, *folios*.

wards become more easily recognisable. In the following sentence it is at once perceived what relation the first *is* expresses, but much more difficult to get the distinct idea meant to be conveyed by the second:—'Diogenes sat *in* a tub, but he was generally *in* good-humour.'

When a noun ending in *y* is to be formed into the plural, *s* is added if the *y* is preceded by a vowel; but if a consonant goes before the *y*, then the *y* is changed into *ies*; thus, in *boy*, there is a vowel before the *y*, we therefore add *s*, *boys*; but in *duty* there is a consonant before the *y*, the plural therefore is *duties*.

Nouns ending in *f* or *fe*, generally form the plural by changing the *f* or *fe* into *ves*; thus, *loaf*, *loaves*; *knife*, *knives*; *wife*, *wives*.

*Hoof*, *hoofs*; *proof*, *proofs*; *roof*, *roofs*; and a few others, are exceptions.

Nouns derived from dead or foreign tongues for the most part retain their original plurals; thus—

From the Latin we have—

SINGULAR.	PLURAL.
Effluviū	Effluvia
Radius	Radii
Larva	Larvæ
Vortex	Vortices
Axis	Axes
Genus	Genera
Magus	Magi
Medium	Media
Nebula	Nebulæ
Stratum	Strata.

From the Greek come—

SINGULAR.	PLURAL.
Phenomenon	Phenomena
Crisis	Criees
Hypothesis	Hypotheses
Criterion	Criteria
Automaton	Automata
Theis	Thees
Elipseis	Elipses
Metamorphosis	Metamorphoses
Analysis	Analyses.

The Hebrew words *cherub* and *seraph* form their plurals *cherubim* and *seraphim*; and the French *deux* and *monsieur* form their plurals *deux* and *messieurs*, which last is contracted into *messrs*.

A few nouns, in very common use, form their plurals quite anomalously; thus—

SINGULAR.	PLURAL.
Man	Men
Foot	Feet
Tooth	Teeth
Mouse	Mice
Goose	Geese.

GENDER.—Gender is that accident of a noun which points out the sex or the absence of sex. Every existence is either male or female, or neither the one nor the other. The Masculine Gender includes all males; the Feminine, all females; and the Neuter, all things destitute of sex, or animals when the sex is not regarded.

Adam Smith remarks, that 'in many languages the qualities both of sex and of the want of sex are expressed by different terminations in the nouns substantive which denote objects so qualified.' After showing that, in Latin, certain terminations were appropriated to expressing certain genders, he adds—'The quality [of sex] appears in nature as a modification of the substance; and as it is thus expressed in language by a modification of the noun substantive which denotes that substance, the quality and the subject are in this case blended together, if I may say so, in the expression, in the same manner as they appear to be in the object and in the idea. Hence the origin of the masculine, feminine, and neuter genders, in all the ancient languages.'

Admitting the truth as well as the ingenuity of this speculation, as far as regards ancient languages, it does not appear to be the *genius* of the English language to assign any particular termination (as we find in the Latin) to the different genders; there are, however, some cases in which gender may be recognised from the mere termination of the noun, as will appear from the following table:—

MASCULINE.	FEMININE.
Actor	Actress
Governor	Governess
Heir	Heiress
Lion	Lioness
Master	Mistress.

In some cases difference of sex is expressed by a totally different word, and the gender cannot be known but by knowing the exact idea attached to the word. Of this sort are the following:—

MASCULINE.	FEMININE.
Boy	Girl
Father	Mother
Brother	Sister.

Sometimes the same word is applied to males and females indiscriminately; and when we wish to distinguish the sex, we prefix another word. Thus the word *servant* signifies either a male or a female; but if we desire to notify which, we can use the compound words *man-servant* or *maid-servant*. Of the same kind are *he-goat* and *she-goat*, *cook-sparrow* and *hen-sparrow*, and many others.

**CASE.**—Case is that accident of a noun which points out the relation which it bears to other parts of the sentence.

Nouns have three cases—Nominative, Possessive, and Objective.

The noun is said to be in the Nominative when it is the subject of discourse, and represents the person or thing of whom or which some assertion is made. Thus in the sentence, 'John reads,' the proper noun *John* is said to be in the Nominative, because it names the person of whom the assertion *reads* is made.

The Possessive represents a vast variety of relations, but the principal one is that of ownership or possession. Thus, 'John's book is lost,' where *John's* is in the possessive, because it names the owner of the *book*.\*

The inflection of the Possessive Case (the only case in English that has an inflection) corresponds exactly in import to the preposition *of*. In the line,

'An angel's virtues and a woman's love,'

we could easily dispense with the possessive, and introduce the preposition, where the whole meaning would be preserved; thus,

The virtues of an angel and the love of a woman.

Adam Smith asserts that inflections would probably be made before prepositions were invented; observing very justly, that it requires much less abstraction to express the nature of the relation that subsists between two objects by a change on the name denoting one of them, than to call into use a class of words expressing relation and nothing else. 'To express relation by a variation in the name of the correlative object, requiring neither abstraction nor generalisation, nor comparison of any kind, would at first be much more natural and easy than to express it by those general words called prepositions, of which the first invention must have demanded some degree of all these operations.'

This speculation is exceedingly ingenious; but whether it be true in general is, to say the least, doubtful; and as far as the possessive of the English noun goes, it must be allowed, we think, to be wide of the truth.

The noun is in the Objective Case—1st, when it names the object on which the action expressed by a transitive verb operates; and 2d, when it names the thing shown to be related to something else by a preposition. In the sentence, 'John destroyed his book,' *book* is expressing the object on which the verbal action operates; it is therefore said to be in the objective case. Again, in the sentence, 'The cloud rises over the hill,' *hill* is in the objective, because it is the word shown to be related to *cloud* by the preposition *over*.

\* Concerning the origin of the possessive case English grammarians and critics are not agreed. Some maintain that it is what we may call indigenous to the language, corresponding, they affirm, to an inflection of the Saxon noun; but we rather incline to the opinion of Addison, who thinks that the possessive termination is only a contraction for the pronoun *his*. Had the possessive case been native to our tongue, it is hardly conceivable that the translators of the Bible would have used such an expression as 'Aas his heart was perfect.' It has been ingeniously objected to Addison's explanation, that while it is very easy to see how 'the king his crown' might have been contracted or corrupted into 'the king's crown,' it is impossible to imagine that 'the queen her crown,' or 'the children their bread,' could have been subjected to the same contraction. But surely this objection is not unanswerable; for when the convenience of the contraction was seen in the case of singular nouns masculine, it might very easily be transferred to nouns feminine and plural. We would not be understood, however, to speak confidently on the point; and in whatever way the possessive was introduced, it is now impossible, supposing it were desirable, to displace it.

The Nominative and Objective of nouns are alike in form; and it is only by observing how the noun stands related to other words, that we can say when it is in the one and when in the other. To decide on the case of a noun, we must 'look before and after.' The Possessive, however, may be recognised by its form, as well as by its function, as it for the most part ends with 's in the singular, and ' after the *s* in the plural.

A noun is thus declined:—

	SINGULAR.	PLURAL.
<i>Nominative.</i>	Brother	Brothers
<i>Possessive.</i>	Brother's	Brothers'
<i>Objective.</i>	Brother	Brothers.

When the plural does not end in *s*, the Possessive is formed in the same way as the singular; thus—

	SINGULAR.	PLURAL.
<i>Nominative.</i>	Man	Men
<i>Possessive.</i>	Man's	Men's
<i>Objective.</i>	Man	Men.

**Inflection of Adjectives.**

In many languages the Adjective is changed in termination, to correspond with the noun which it qualifies; but in the English tongue there is no such modification; and here, as in many other respects, our language seems superior in metaphysical propriety to most others, because the accident of gender cannot properly belong to a quality which is itself but an accident and no self-existing thing. 'Gender,' it is observed by Adam Smith, 'cannot properly belong to a noun adjective, the signification of which is always precisely the same, to whatever species of substantives it is applied.' When we say "a great man," "a great woman," the word *great* has precisely the same meaning in both cases, and the difference of the sex in the subjects to which it may be applied makes no sort of difference in its signification. *Magnus, magna, magnus*, in the same manner, are words which express precisely the same quality, and the change of the termination is accompanied with no sort of variation in the meaning. Sex and gender are qualities that belong to substances, but cannot belong to the qualities of substances.'

But while the nature of the thing which the adjective is employed to express cannot be varied, yet it may exist in different proportions; and hence the adjective is varied to express different degrees of the quality indicated by it, and these variations are called Degrees of Comparison.

When the simple quality is denoted, the adjective is said to be in the Positive Degree. When a higher degree is signified, the adjective is in the Comparative; and when the highest degree is expressed, it is said to be in the Superlative. Logically considered, indeed, the positive involves the idea of comparison as much as the comparative; thus, when we affirm of a mountain that it is *lofty*, we must have a tacit reference to other mountains; when we affirm of any particular river that it is *rapid*, we (unconsciously, perhaps, but yet actually) make a comparison between it and some other rivers. We consider it, therefore, impossible to state any essential difference between the degrees of comparison; but in addition to what we have already said, we may mention that the comparative degree denotes that the quality expressed by it belongs to one of two objects in a greater degree than to the other; and the superlative, that it belongs to one of several in a greater degree than to any of the rest. For example, when we say that the line A— is longer than the line B—, the meaning is, that both lines have a certain quality—length, but that A has more of it than B. When the comparison is drawn between more things than two, we use the superlative. Thus, we say of the lines A—, B—, C—, D—, that C is the longest. In the same way, speaking of stone and wood, we might say, 'Stone is the *hardest* body of the two;' but if we are discoursing of iron, stone, and wood, we must use the superlative, and say, 'Iron is the *hardest* body of the three.'

The whole class of Numeral Adjectives, from their

very nature, cannot be in any other degree than the positive; and with respect to Attributive Adjectives, it is to be observed that those only which express a quality which may exist in greater or less proportions can be compared: for instance, if the exact ideas represented by the words *circular, square, triangular*, and also such words as *chief, extreme, universal, true*, and *eternal*, be apprehended by the mind, by the very act of apprehension it will be seen that it would be contradictory to their nature to admit of any increase. Let the student reflect on this, and then he will be able to dispense with rules about the use of *chief, perpendicular, &c.* because he will see at once, from the nature of the idea suggested by the word, whether it admits of increase or diminution.

The Comparative is formed by adding *er* to the Positive, if it end with a consonant, and *r* simply, if it end in the vowel *e*; thus, hard, harder; large, larger.

Adjectives compared in this manner are said to be Regular; but some adjectives follow no fixed rule in forming their degrees of comparison, and these are called Irregular. The following are those most commonly in use:—

POSITIVE.	COMPARATIVE.	SUPERLATIVE.
Good	Better	Best
Bad	Worse	Worst
Little	Less	Least
Much or many	More	Most
Late	Later	Latest or last
Near	Nearer	Nearest or next.

Sometimes the same idea is conveyed by prefixing an adverb to the adjective in its simple state: thus instead of saying *juster*, we might say *more just*; but it is not therefore to be inferred that *more just* is the comparison of *just*. Were this principle admitted, we should soon have inextricable confusion. In such cases, *more* is an adverb in the comparative, qualifying the adjective *just*, and the two words should be parsed separately. The prefixing of an adverb cannot, with any justice, be called a variation of the adjective.

A few adjectives have a plural form, particularly the demonstrative, *this* and *that*; in the plural, *these* and *those*: *one, other, and another*, are also sometimes varied by number or case.

Inflection of Pronouns.

The Pronoun, like the Noun, is varied by Gender, Number, Person, and Case.

The Personal Pronouns are thus declined:—

SINGULAR NUMBER.			
NOMINATIVE.	POSSESSIVE.	OBJECTIVE.	
1st Person, I	Mine	Me	
2d ... Thou	Thine	Thee	
3d ... He, she, it	His, hers, its	Him, her, it.	
PLURAL NUMBER.			
NOMINATIVE.	POSSESSIVE.	OBJECTIVE.	
1st Person, We	Ours	Us	
2d ... Ye or you	Yours	You	
3d ... They	Theirs	Them.	

By inspecting the two following lines, the student will understand what we meant by saying, that the Possessive Pronouns, or, as we prefer calling them, Pronominal Adjectives, were derived from, and corresponded with, the personal pronouns:—

I	thou	he	she	it	we	you	they
mine	thine	his	hers	its	ours	yours	theirs.

The Relative and Interrogative Pronouns, *who* and *which*, are alike in both numbers, and are thus declined:—

	Who.	Which.
Nominative.	Who	Which
Possessive.	Whose	Whose
Objective.	Whom	Which.

That and as are indeclinable.

Inflection of Verbs.

The Verb is varied in *four* ways—namely, by Number, Person, Mood, and Tense.

There are two Numbers—singular and plural—as in the case of the noun; and three Persons, as in the pronouns.

The Moods are generally reckoned *five* in number—the Indicative, the Subjunctive, the Potential, the Imperative, and the Infinitive. But it may well be questioned if there is any real ground for such distinction, as far at least as the Subjunctive and Potential are concerned. The Subjunctive, as it is called, is merely an elliptical mode of expression, and the Potential is made up of two or more verbs, and therefore it can with no propriety be called an *inflection* of any one of them.

This leaves us the Indicative, by which simple assertions are made; the Imperative, by which commands are issued; and the Infinitive, which is neither more nor less than the name of the verb, and in use corresponds exactly to a noun.

The Tenses are two in number—the Present and the Past: the Future is not expressed by any *inflection* of the verb in English, as it is in Latin, French, and other languages, but by the help of another verb; and it is surely absurd to force a distinction upon the English verb merely because it exists in Latin.\*

The Participles of the verb are likewise two in number—the Perfect and the Imperfect. They are often called the Present and Past, but in themselves they have no reference to time, and merely indicate the *completion* or *non-completion* of an action.

According to this view of the verb—the only consistent one—it has no such thing as a passive voice. What is called the passive voice is not formed by any variety of termination, and so cannot be acknowledged as an *inflection*, without opening a door to all manner of confusion.

'The English verb,' says Crombie in his 'Treatise on the Etymology and Syntax of the English Language,' 'has only one voice—namely, the active. Dr Lowth, and most other grammarians, have assigned it two voices—active and passive. Lowth has in this instance not only violated the simplicity of our language, but has also advanced an opinion inconsistent with his own principles. For if he has justly excluded from the number of cases in nouns, and moods in verbs, those which are not formed by inflection, but by the addition of prepositions and auxiliary verbs, there is equal reason for rejecting a passive voice, if it be not formed by variety of termination. Were I to ask him why he denies *from a king* to be an ablative case, or *I may love* to be the potential mood, he would answer, and very truly, that those only can be justly regarded as cases or moods which, by a different form of the noun or verb, express a different relation or a different mode of existence. If this answer be satisfactory, there can be no good reason for assigning to our language a passive voice, when that voice is formed not by inflection, but by an auxiliary verb. *Docet* [being an inflection of the word *doceo*] is truly a passive voice; but *I am taught* cannot, without impropriety, be considered as such.'

By *conjugating* a verb is meant mentioning the present and past tenses and the perfect participle.

The past tense and perfect participle are formed from the present tense by adding *ed* if it end in a consonant, as *rain, rained*; and simply *d* if it end in a vowel, as *change, changed*.

If these parts are formed in any other way, the verb

\* A little reflection may, I think, suffice to convince any person that we have no more business with a *future tense* in our language than we have with the whole system of Latin moods and tenses; because we have no modification of our verbs to correspond to it; and if we had never heard of a future tense in some other language, we should no more have given a particular name to the combination of the verb with the auxiliary *shall* or *will*, than to those that are made with the auxiliaries *do, have, can, must, or any other.*—PRIESTLEY'S *Elements of English Grammar.*

CHAMBERS'S INFORMATION FOR THE PEOPLE.

is called Irregular; and if it wants any of them, it is said to be Defective.

We subjoin a few of the Irregular Verbs in most frequent use, or in which mistakes are apt to arise:—

PRESENT.	PAST.	PERFECT PARTICIPLE.
Am	was	been
Arise	arose	arisen
Awake	awoke r*	awaked
Bear (to carry)	bore	born
Bear (to bring forth)	bare	born
Bereave	bereft r	bereft
Beseech	besought	besought
Bid	bade	bid
Bite	bit	bitten
Build	built r	built
Catch	caught	caught
Choose	chose	chosen
Cleave (to split)	cleft, clove	cleft, cloven
Cleave (to cling to)	clavo	cleavod
Clothe	clothed	clothed, clad
Crow	crew	crowed
Dare (to venture)	durst	dared
Dare (to challenge)	dared	dared
Deal	dealt	dealt
Drink	drank	drunk, drunken
Eat	ate	eaten
Fly	flew	flown
Freeze	froze	frozen
Hang	hung	hung, hanged
Hide	hid	hidden, hid
Lay (to deposit)	laid	laid
Lie (as on a bed)	lay	lain
Ring	rang, rung	rung
Rive	rived	riven
Run	ran	run
Shake	shook	shaken
Shoe	shod	shod
Shrink	shrank	shrank
Slink	slunk	slunk
Spit	spit	spit
Swim	swam, swum	swum
Take	took	taken
Tare	tore	torn
Tread	trod	trodden
Wax	waxed, waxen	waxed
Wear	wore	worn
Win	won	won
Worked	wrought	wrought r.

The Regular Verb is thus inflected:—

To LOVE.		
Present Tense.	Past Tense.	Perfect Participle.
Lov <sup>d</sup> .	Lov <sup>d</sup> .	Lov <sup>d</sup> .
PRESENT TENSE.		
SINGULAR.	PLURAL.	
1st Person, I lov <sup>e</sup> .	1st Person, We lov <sup>e</sup>	
2d ... Thou lov <sup>est</sup>	2d ... Ye or you lov <sup>e</sup>	
3d ... He lov <sup>es</sup> .	3d ... They lov <sup>e</sup> .	
PAST TENSE.		
SINGULAR.	PLURAL.	
1. I lov <sup>ed</sup>	1. We lov <sup>ed</sup>	
2. Thou lov <sup>edst</sup>	2. Ye or you lov <sup>ed</sup>	
3. He lov <sup>ed</sup> .	3. They lov <sup>ed</sup> .	
<i>Imperative, Lov<sup>e</sup>. Infinitive, To lov<sup>e</sup>.</i>		
PARTICIPLES.		
<i>Imperfect, Lov<sup>ing</sup>. Perfect, Lov<sup>ed</sup>.</i>		

The verb *To Write* is irregular, and is thus conjugated and declined:—

To WRITE.		
Present Tense.	Past Tense.	Perfect Participle.
Writ <sup>e</sup> .	Wrot <sup>e</sup> .	Writt <sup>e</sup> n.
PRESENT TENSE.		
SINGULAR.	PLURAL.	
1. I writ <sup>e</sup>	1. We writ <sup>e</sup>	
2. Thou writ <sup>est</sup>	2. Ye or you writ <sup>e</sup>	
3. He writ <sup>es</sup> .	3. They writ <sup>e</sup> .	
PAST TENSE.		
SINGULAR.	PLURAL.	
1. I wrot <sup>e</sup>	1. We wrot <sup>e</sup>	
2. Thou wrot <sup>est</sup>	2. Ye or you wrot <sup>e</sup>	
3. He wrot <sup>e</sup> .	3. They wrot <sup>e</sup> .	
<i>Imperative, Writ<sup>e</sup>. Infinitive, To writ<sup>e</sup>.</i>		
PARTICIPLES.		
<i>Imperfect, Writ<sup>ing</sup>. Perfect, Writt<sup>e</sup>n.</i>		

\* The verbs which are conjugated regularly as well as irregularly are marked with an *r*. Thus the past tense of *awake* is either *awoke* or *awaked*; of *build*, *buildd*, or *built*.

The Irregular Verbs, *Be, Do, Have*, and the Defective Verbs, *Shall, Will, May, Can*, from their frequent occurrence, ought to be carefully examined. Tables of them are here presented:—

To BE.		
Present Tense.	Past Tense.	Perfect Participle.
Am.	Was.	Been.
PRESENT TENSE.		
SINGULAR.	PLURAL.	
1. I am	1. We are	
2. Thou art	2. Ye or you are	
3. He is.	3. They are.	
PAST TENSE.		
SINGULAR.	PLURAL.	
1. I was	1. We were	
2. Thou wast	2. Ye or you were	
3. He was.	3. They were.	
<i>Imperative, Be. Infinitive, To be.</i>		
PARTICIPLES.		
<i>Imperfect, Being. Perfect, Been.</i>		

The verb *To Be* has a peculiar inflection, to express contingency or conditionality, which we here subjoin. It may be called the Conditional or Subjunctive Mood. In the case of other verbs, this form is elliptical.

CONDITIONAL TENSE OF THE VERB To BE.

To DO.		
Present Tense.	Past Tense.	Perfect Participle.
Do.	Did.	Done.
PRESENT TENSE.		
SINGULAR.	PLURAL.	
1. I do	1. We do	
2. Thou dost or doest	2. Ye do	
3. He does or doeth.	3. They do.	
PAST TENSE.		
SINGULAR.	PLURAL.	
1. I did	1. We did	
2. Thou didst	2. Ye did	
3. He did.	3. They did.	
<i>Imperative, Do. Infinitive, To do.</i>		
PARTICIPLES.		
<i>Imperfect, Doing. Perfect, Done.</i>		

To HAVE.			
Present Tense.	Past Tense.	Perfect Participle.	
Have.	Had.	Had.	
PRESENT TENSE.			
SINGULAR.	PLURAL.	SINGULAR.	PLURAL.
1. I have	1. We have	1. I had	1. We had
2. Thou hast	2. Ye have	2. Thou hadst	2. Ye had
3. He has.	3. They have.	3. He had.	3. They had
<i>Imperative, Have. Infinitive, To have.</i>			
PARTICIPLES.			
<i>Imperfect, Having. Perfect, Had.</i>			

SHALL.			
PRESENT TENSE.		PAST TENSE.	
SINGULAR.	PLURAL.	SINGULAR.	PLURAL.
1. I shall	1. We shall	1. I should	1. We should
2. Thou shalt	2. Ye shall	2. Thou shouldst	2. Ye should
3. He shall.	3. They shall.	3. He should.	3. They should
WILL.			
SINGULAR.	PLURAL.	SINGULAR.	PLURAL.
1. I will	1. We will	1. I would	1. We would
2. Thou wilt	2. Ye will	2. Thou wouldst	2. Ye would
3. He will.	3. They will.	3. He would.	3. They would

MAY.			
PRESENT TENSE.		PAST TENSE.	
SINGULAR.	PLURAL.	SINGULAR.	PLURAL.
1. I may	1. We may	1. I might	1. We might
2. Thou mayest	2. Ye may	2. Thou mightest	2. Ye might
3. He may.	3. They may.	3. He might.	3. They might

ENGLISH GRAMMAR.

CAN.

PRESENT TENSE.		PAST TENSE.	
SINGULAR.	FLURAL.	SINGULAR.	FLURAL.
1. I can.	1. We can.	1. I could.	1. We could.
2. Thou canst.	2. Ye can.	2. Thou couldst.	2. Ye could.
3. He can.	3. They can.	3. He could.	3. They could.

Inflection of Adverbs.

Adverbs for the most part admit no modification or inflection: a few, however, are compared like adjectives.

Some are Regular, as—

POSITIV.	COMPARATIVE.	SUPERLATIVE.
Soon	Sooner	Soonest
Often	Often	Oftenest
Seldom	Seldomer	Seldomest.

Others are Irregular, as—

POSITIVE.	COMPARATIVE.	SUPERLATIVE.
Well	Better	Best
Badly or ill	Worse	Worst
Little	Less	Least
Much	More	Most.

The student will now be able to *parse* a sentence, mentioning not merely what part of speech any word is, but what *inflection* it has undergone, and how it stands related to other words. By way of example, we shall parse one sentence from Bacon:—

'A single life doth well with churchmen; for charity will hardly water the ground where it must first fill a pool.'

*A*, a numeral adjective, qualifying the noun *life*. It is commonly called the indefinite article.

*Single*, an attributive adjective, designating the noun *life*. It cannot be compared.

*Life*, a noun, singular number, neuter gender, and the nominative case, because it is the thing of which something is asserted. The plural of *life* is *lives*.

*Doth*, a verb, because it asserts something of the noun *life*: it is in the present tense, indicative mood, and the third person singular, to agree with its noun *life*. *Doth* is now almost obsolete, *does* being the word in common use. The verb *To Do* is conjugated thus: *Present Tense*, Do; *Past*, Did; *Perfect Participle*, Done.

*Well*, an adverb, expressing how 'a single life doth.' *Well* is in the positive degree, and is compared thus: *Positive*, Well; *Comparative*, Better; *Superlative*, Best.

*With*, a preposition, used in a metaphorical sense, to connect *churchmen* with *single life*.

*Churchmen*, a noun plural, masculine, and the objective; being the object shown to be related to something else by the preposition *with*. The singular is *churchman*. All nouns, it should be remembered, are of the third person.

*For*, a conjunction, connecting the clause that follows with the one which went before.

*Charity*, a noun, being *primarily* the name of a disposition of mind, and *secondarily* of the course of action resulting from that disposition; singular number, neuter gender, and the nominative to the verb *will*.

*Will*, a verb, present tense, singular number, and third person, to agree with *charity*.

*Hardly* is an adverb of degree, qualifying the verb *water*.

*Water* is a verb in the infinitive mood. *To*, the sign of the infinitive, is suppressed after a great number of verbs, and *will* is one of them. *Will* is a defective verb, and is conjugated thus:—*Present Tense*, Will; *Past Tense*, Would.

*The*, a numeral adjective, or definite article, qualifying the noun *ground*.

*Ground*, a noun, singular, neuter, and the objective, being the thing which is affected by the verb *water*.

*Where* is of the nature of a conjunction, since it unites the two members of the last clause; but it also has in it the force of an adverb, being equivalent to *in the case in which*. We may therefore call it a conjunctive adverb.

It is a personal pronoun, singular, neuter, and third person, supplying the place of the noun *charity*. It is the nominative to the verb *must*.

*Must* is a verb, asserting something of the pronoun *it*. It is in the present tense, and third person singular.

*First* is an adverb of time, qualifying the verb *fill*.

*Fill* is a verb in the infinitive, to being understood after *must*,

in the same way as it was after *will*, in the former part of the sentence.

*A*, a numeral adjective, or indefinite article, designating the noun *pool*.

*Pool*, a noun, singular, neuter, and objective case, being the thing affected by the transitive verb *fill*.

*Additional Remarks*.—Before quitting this division of our subject, we must inform the reader that the same word is frequently used in different ways, and consequently belongs to different parts of speech. Nothing can be more certain than that every word must have been originally significant of only one idea; but in the progress of language other ideas attach themselves to it, and the grammarian must not resist this extension of meaning, but carefully observe it. To discover, then, what class of words any word belongs to, we must 'look before and after;' but a few examples will illustrate our meaning best.

'Come out of the *wet*.' Here *wet* is a noun, because it is a name expressive of a certain state of the elements. 'John threw off his *wet* clothes.' Here *wet* is an adjective, because it qualifies the noun *clothes*. 'A shower came on and *wet* the ground.' Here *wet* is a verb, because it expresses an action. The shower did something—'wet the ground.'

On the following examples let the student exercise himself, in satisfying himself as to the justness of our assertions with regard to the *class* of those words which may belong to one or more:—

1. The sun is the great source of *light* (noun).

Feathers are *light* (adjective).

— And nightly *lights* (verb) the waters with her sheen.

2. Beloved, let us *love* (verb) one another; for *love* (noun) is of God.

3. Then he arose and rebuked the winds and the sea, and there was a great *calm* (noun).

Thy brow is *calm* (adjective) and bright,  
Wearing no trace of sorrow or of sin.

To still the pang that conscience can impart,  
And *calm* (verb) the restless pulses of the heart.

How often have I loitered o'er thy *green* (noun),  
Where humble happiness endeared each scene.

Yet wandering, I found, on my ruinous walk,  
By the dial-stone aged and *green* (adjective).

5. Thy *nightly* (adjective) visits to my chamber made.

When the blue wave rolls *nightly* (adverb).  
On deep Galilee.

6. Yes, there are charms *that* (rel. pron.) scorn the spoiler  
Time!

Blessed are those,  
Whose blood and judgment are so well commingled,  
*That* (conjunctive) they are not a pipe for fortune's finger  
To sound what stop she please. Give me *that* (demonstrative adjective)  
man

*That* (rel. pron.) is not passion's slave, and I will wear him  
In my heart's core.

7. The common *still* (noun) can only be employed, &c.

Hope quickens the *still* (adjective) parts of life.

Is this the Talbot so much feared abroad,  
That with his name the mothers *still* (verb) their babes?

It hath been anciently reported, and is *still* (adverb) reported, &c.

John has been very foolish, *still* (conjunctive) I will not dismiss him.

Let the student further exercise himself in what respects one part of speech resembles another, and wherein it differs. He will find that the noun and pronoun, adjective and adverb, preposition and conjunction, resemble each other in some respects, but that they yet are quite distinct.

We conclude this subject with two brief extracts from Locke's 'Essay on the Human Understanding,' book iii. chap. 7:—'Besides words which are names of ideas in the mind, there are a great many others that

are made use of to signify the connection that the mind gives to ideas or propositions one with another. The mind, in communicating its thought to others, does not only need signs of the ideas it has then before it, but others also, to show or intimate some particular action of its own, at that time, relating to those ideas. This it does several ways; as *is* and *is not* are the general marks of the mind affirming or denying. But besides affirmation or negation, without which there is in words no truth or falsehood, the mind does, in declaring its sentiments to others, connect not only the parts of propositions, but whole sentences, one to another, with their several relations and dependencies, to make a coherent discourse.

Though prepositions and conjunctions are names well known in grammar, and the particles contained under them carefully ranked into their distinct subdivisions, yet he who would show the right use of particles, and what significance and force they have, must take a little more pains, enter into his own thoughts, and observe nicely the several postures of his mind in discoursing.

Whoever wishes really to understand the nature and use of words, should study carefully the third book of Locke's invaluable essay.

III.—DERIVATION.

Derivation is that part of Etymology which traces words to their original form and signification.

The ideas attached to words are purely arbitrary and conventional; there being no reason, for instance, why the sound represented by the combination of letters *fire* should suggest the idea of heat, while that of *ice* should give the notion of cold. From this principle it follows, that the real import of any word can be ascertained only by *induction*—that is, by observing the common idea which it suggests in every different position that it may occupy. Some, indeed, have affirmed, that in order to ascertain with precision the philosophical import of a word, it is necessary to trace its progress historically, through all the successive meanings it has been employed to convey, from the moment that it was first introduced into the language; and others, not content with this, prosecute their etymological research till they arrive at the literal and primitive sense of the root from which it springs. But it may well be doubted if such a course of procedure is followed by any substantial benefit at all proportionate to the labour which it imposes on the student; and one thing is certain, that an appeal to etymology from use is altogether nugatory, and displays an utter ignorance of the nature and function of words. The derivation or pedigree of a word will by no means universally lead to its real meaning. Horne Tooke and his followers have employed themselves in tracing words to their sources, and with wonderful success; but their speculations, however interesting in some respects, are almost useless, as far as the grammar of our language is concerned; and certainly, though that school of philologists should succeed to their utmost desire in chasing every word now in use up to some Icelandic or Gothic origin, it would in no way interfere with the present structure of the English tongue. It may be very interesting to trace our language from the period when it was only the rude jargon of wandering hordes of savages, down to the present time, when it is capable of expressing with precision the minutest distinctions of the metaphysician or the most glowing conceptions of the poet; but it belongs rather to the philologist to enter on such investigations than the grammarian. Still, some ground is common to both, and it is necessary to say a few words on the subject.

Words are usually divided into two classes—*Primitive* and *Derivative*.

A Primitive word is one not derived from any other word in the language; as, *man, school*.

A Derivative word is either compounded of two significant words in the language, or of one significant

word and some termination that modifies its meaning; as, *schoolman, scholar*.

The bulk of the English language is Anglo-Saxon, and so are the forms of its grammar. A considerable number of its words, however, are from the Latin, and not a few from the Greek, both as entire words, and as parts of words or prefixes. [For further information on this point, the reader is referred to the article LANGUAGE, No. 52.] The following is a list of these Prefixes, together with examples of the manner in which they enter into combination with other words:—

LATIN PREFIXES.

- A, ab, or abs,* from; as, *avert*, to turn from; *absolve*, to loose from; *abstract*, to draw from; *abnormal*, from the rule.
- Ad,* to; as, *adhere*, to stick to.
- Am,* round about; as, *ambition*, literally, a going round about.
- Ante,* before; as, *antecedent*.
- Circum,* round; as, *circumnavigate*.
- Con, col, cor,* together; as, *conjoin, convoke, collect, correct*—the *n* being changed into *l* and *r* respectively for the sake of euphony.
- Contra,* against; as, *contradict*.
- De,* down; as, *destroy, demolish*.
- Di or dis,* asunder; as, *divert, dissolve*.
- E or ex,* out of; as, *evolve, extract*.
- Extra,* beyond; as, *extraordinary*.
- In,* in or into; as, *inject*.
- Inter,* between; as, *intervene*.
- Intro,* within; as, *introduce*.
- Iusta,* nigh to; as,  *juxtaposition*.
- Ob, op,* in the way of; as, *obstruct, oppose*.
- Per,* through; as, *performe*.
- Post,* after; as, *postpone*.
- Pre,* before; as, *prefix*.
- Pro,* instead of; as, *pronoun*.
- Præter,* beyond; as, *præternatural*.
- Re,* back; as, *replacé*.
- Retro,* backward (implying motion); as, *retrograde*.
- Se,* aside; as, *secede*.
- Sub,* under; as, *sublunary*.
- Super,* above; as, *superinduce, superfluous*.
- Trans,* across; as, *transport, transatlantic, transgress*.

GREEK PREFIXES.

- A,* without; as, *anomalous, amorphous*.
- Amphi,* both; as, *amphibious*.
- Ana,* up, through; as, *anatomy*.
- Anti,* against; as, *Antichrist*.
- Apo,* from, away; as, *apostate*.
- Cata,* down; as, *calastropha*.
- Dia,* through; as, *diagonal*.
- Epi,* upon; as, *epilogue, epidemic*.
- Hyper,* overmuch; as, *hypercritical*.
- Hypo,* under; as, *hypocrite*.
- Meta,* change; as, *metamorphosis*.
- Para,* near to; as, *paraphrase*.
- Peri,* round about; as, *perimeter*.
- Syn,* together; as, *synod, synagogue*.

Affixes.

It is not so easy to trace the Affixes to their original meaning, as they now seldom retain any signification when taken by themselves, but are used merely to modify other words. We shall present a few of them, with examples, but we are far from thinking that the list is complete:—

AFFIXES FORMING NOUNS.

- |  |   |  |   |
|--|---|--|---|
| <p><i>an</i><br/><i>ant</i><br/><i>ar</i><br/><i>ard</i><br/><i>ary</i><br/><i>cer</i><br/><i>ent</i><br/><i>er</i><br/><i>ist</i><br/><i>or</i><br/><i>ster</i></p> | } | <p>denoting the agent, or doer of a thing; as,</p> | <p>Tragedian, historian.<br/>Claimant, combatant.<br/>Scholar, liar.<br/>Drunkard, dotard.<br/>Adversary, auctioneer.<br/>Engineer, auctioneer.<br/>Adherent, correspondent.<br/>Accuser, believer.<br/>Apologist, Chartist.<br/>Actor, Creator.<br/>Punster, spinster.</p> |
|--|---|--|---|

AFFIXES FORMING VERBS.

- |  |   |                                       |  |
|--|---|---------------------------------------|--|
| <p><i>en</i><br/><i>fy</i><br/><i>ise</i> or <i>ize</i><br/><i>ate</i></p> | } | <p>denoting to make or cause; as,</p> | <p>Harden, strengthen.<br/>Purify, clarify.<br/>Civilize, equalize.<br/>Alienate, assassinate.</p> |
|--|---|---------------------------------------|--|

AFFIXES FORMING ADJECTIVES.

ful  
ly  
some  
y  
less

denoting full of,  
or abounding  
in; as,

Artful, beautiful.  
Bounteous, plenteous.  
Fatherly, homely.  
Troublesome, toilsome.  
Wealthy, mighty.  
Democratical, methodical.  
Expansive, instructive.

AFFIXES FORMING ABSTRACT NOUNS.

ment  
ness  
sion  
tion  
ty  
hood  
ship  
dom  
rude

denoting  
state of,  
considered  
abstractedly.

Amusement, abatement.  
Goodness, hardness.  
Convulsion, expansion.  
Production, vindication.  
Pleety, probrity.  
Childhood, manhood.  
Friendship, courtship.  
Christianism, kingdom.  
Bishopric.  
Lessitude, fortitude.

All words must originally have had only one meaning, but subsequently they come to, have various secondary significations. These are attached to them according to fixed laws of the association of ideas; but in the case of each individual word, the signification must be inferred from the relation which it bears to the other words with which it stands connected.

A very large and important class of words, whose primary signification refers to the operation of sensible things, are applied secondarily to modes of thinking; as, imagine, apprehend, comprehend, adhere, conceive, instil, disgust, disturbance, tranquillity, abstraction, sincere, foresight, penetration, acuteness, inclination, aversion, deliberation, sagacity, attention, &c. But the prosecution of this subject falls more within the province of the logician than the grammarian, and here we may draw our observations on derivation to a close.

SYNTAX.

SYNTAX—from two Greek words, *syn*, together, and *taxis*, a putting or placing—is that part of grammar which shows how words are connected and arranged.

Etymology, we have seen, treats of the materials of language, *individual words*; but it is the business of *Syntax* to point out by what rules these words are put together, so as to form *sentences*. By a *sentence* is meant a number of words so united as to make sense; that is, to declare or affirm something: thus the words, 'The city of Edinburgh,' do not form a sentence, because they declare nothing; but if we say, 'The city of Edinburgh is the capital of Scotland,' a distinct assertion is made, and therefore the words form a sentence.

We must here remind the reader that every sentence must contain at least a subject and a predicate, the subject being the thing spoken of, and the predicate the action or state of being affirmed of it.

When the verb forming the predicate is transitive, the word which it affects is called the *object*: thus in the sentence, 'John learns his lesson,' *John*, being the subject of discourse, is in the nominative, and *lesson*, being the thing affected by the predicate *learns*, is in the objective case.

RULES OF SYNTAX.

Rule I.—Nominative and Verb.

A verb agrees with its nominative in number and person; as, *I read, he learns*.

This rule is of very extensive application, and if understood in its full import, it will render useless many others that are commonly set down by grammarians. It may be expressed in more general terms thus: The number and person of the subject of a sentence determine the number and person of the verb. For example, in the sentence, 'John runs,' *John*, the subject, is singular, and, like all nouns, of the third person; we therefore use the third person singular of the verb, *runs*. Again, in the sentence, 'John and James read,' the subject, *John and James*, expresses an

idea of more than one, and so the verb must be plural—*read*, not *reads*, as it would have been had only one name been mentioned. In this sentence, 'John or James intends to accompany me,' it is obvious, from the very nature of the conjunction *or*, that *intention* is predicated or asserted only of one of the persons, and therefore the verb is in the singular, *intends*.

As collective nouns, though singular in form, may yet suggest the idea of plurality, they are joined either to a singular or a plural verb, according as the idea suggested is that of unity or plurality. Thus when we say, 'The army is on its march,' we seem to lose sight of the individuals composing the idea represented by the word *army*, and speak of it as one mass; but if we say, 'The peasantry go barefooted,' this mode of expression seems to give us an idea of a number of people existing separately, and we therefore put the verb in the plural. With respect to the collective noun, the only thing further to be observed is, that if in one part of the sentence it is made to stand as singular, it ought not in another to be used as plural.

A noun is sometimes put in the nominative, even when it is not the *subject* of the sentence, but merely stands connected with a participle; thus in these lines of Cowper—

'Thou, as a gallant bark from Albion's coast  
(The storms all weathered, and the ocean crossed)  
Shoots into port,' &c.

the words *storms* and *ocean*, joined to the participles *weathered* and *crossed*, are neither the nominatives to any verb, nor are they the *object* affected by a transitive verb or a preposition. Still, they are in the nominative; and this construction is known among grammarians as the nominative absolute. Some grammarians, indeed, contend, and not without reason, that there is an absolute case, quite distinct from the nominative; and that to speak of the 'nominative absolute' involves a contradiction of ideas. It must at once be conceded, that the noun conveys very different ideas in the two cases referred to, and we cannot well deny that they ought to have separate names, in the same manner as we give different names to the nominative and objective, although they are the same in form.

In every case, the *idea* represented by the *subject* must be carefully noticed, and then the *predicate* be conformed to it.

To each rule we shall subjoin a few examples of erroneous construction, being persuaded, in common with Crombie, of the truth of Lowth's remark, that a good way 'of teaching right, is to show what is wrong.'

1. This *course* of lectures were delivered last spring.
2. In the human species, the *influence* of reason and instinct are generally assisted by the lessons of experience.
3. Was you present at the meeting?
4. There are abundance of treatises on that subject.
5. At this time, the *House of Commons* were of little weight.
6. Every one of these theories are unfounded.
7. Was the master and his scholars there?

Rule II.—Possessive Case.

When the relation of ownership is to be pointed out, the Possessive Case of the noun denoting the owner is used: thus, 'This is John's hat.' Here the relation of ownership is to be declared as existing between the person *John* and the thing *hat*, and consequently the name of the possessor is put in the possessive case.

If the name of the owner be a compound name, the last of the component parts only receives the sign of the possessive: thus, 'the Queen of Great Britain's prerogative;' also when there are two separate names, as, 'Robertson and Reid's office.'

- 1 This is John Thomson *his* book.
- 2 James is in Walker's and Son's office.
- 3 Charles is a member of the Mechanic's Institution.
- 4 Have you read Chamber's Journal?

Rule III.—Objective Case.

Active transitive verbs and prepositions take the Objective Case after them thus: 'Do justice, love mercy, and walk humbly with God.' In this sentence, *justice* and *mercy* are in the objective, being affected by the verbs *do* and *love* respectively; and *God* is also in the objective, being the object of the relation pointed out by the preposition *with*.

Some active transitive verbs appear to take two objective cases after them; but it is much more consistent with the analogy of the language to understand a preposition: thus, 'He sent me the book,' where *me* and *book* are both in the objective. It is quite clear that *book* is the thing immediately affected by the verb *sent*, it therefore must be in the objective; but as to *me*, it seems most natural to understand the preposition *to*, when the sentence would be, 'He sent the book to me.' Ellipses of this sort are quite common, and it is altogether unnecessary to bring in any new grammatical rule or principle to account for idiomatic expressions thus produced.

Under this rule we may further observe that all words denoting *measure*, whether of time or space, are capable of being put in the objective, a preposition being understood. Thus in the sentences, 'The wall is seven feet high,' 'I was three days in the country,' the words *feet* and *days* are in the objective, the preposition *for* or *during* being understood. As, however, the nominative and objective of all nouns in English are alike (suffer no inflexion), this remark must be allowed to be of limited utility.

1. I told *ye* that I would come.
2. Who should I love, if not my father?
3. Do you know *who* you speak to?
4. He that can doubt whether he be anything or not, I speak not to.—LOCKE.

Rule IV.—Pronouns.

Pronouns agree in gender, number, person, and case with the nouns for which they stand, and are in all respects to be treated as the nouns would have been had they been used. In the sentence, 'The master instructs his pupils,' the pronoun supplies the place of the possessive case of the noun *master*, which is of the singular number, third person, and masculine gender; we therefore use *his*, which corresponds to all this. Again, 'John and James learn their lesson:' here *their* stands for two nouns, and so must be plural.

1. Thou shalt also make a *laver* of brass, and *his* foot also of brass.
2. For my name and memory, I leave it to men's charitable speeches, and to foreign nations, and to the next age.—BACON.
3. Rebekah took gladly *raiment* that was in the house, and put them on Jacob.
4. I saw the whole species delivered from their sorrows.—ADDISON.
5. Those are the *birds* whom we call gregarious.

Rule V.—The Infinitive.

One verb governs another in the Infinitive: as, 'He loves to study,' where *to study* is the object of the verb *loves*.

Before the verb denoting the object of the predicating verb, the preposition *to* is generally put; and it is in this case called the *sign of the infinitive*. But as we already saw that the infinitive is nothing but a noun, the utility of this rule may well be questioned.

The sign *to* is omitted after the following verbs:—Bid, can, dare, feel, hear, let, make, may, must, need, shall, see, and will. We do not say, 'He bade me to go,' but, 'He bade me go.' The infinitive of a verb may also come after a noun or an adjective, as well as after another verb.

1. Sylla obliged them submit to such terms as the senate were pleased to impose. (See also Rule I.)
2. The king caused them feel the weight of his displeasure.
3. I desired him call in the evening.
4. You need not to trouble yourself on my account.
5. God maketh the sun to rise on the evil and on the good.

Rule VI.—Apposition.

Nouns and pronouns added to other nouns and pronouns to explain them, are put in the same case; thus, 'Edinburgh, the capital of Scotland, is celebrated for its university.' Here *Edinburgh*, being the subject of the sentence, is in the nominative; and the noun *capital*, with its adjunct *of Scotland*, being added to explain it, is in the nominative also. The two words, in cases of this kind, are said by grammarians to be in apposition.

'Brutus killed Caesar in the Capitol; him who had been his friend.' Here *Caesar* is in the objective, governed by the verb *killed*; and as the succeeding pronoun refers to it, it must be in the objective too. If it were *he*, there would be no violation of any rule in grammar, but a misrepresentation of a historical fact, as it would lead us to believe that Brutus befriended Caesar, whereas it was Caesar that had befriended Brutus.

There seems to be an exception to this rule in such expressions as, 'I called at Smith's the bookseller,' where *Smith's* and *bookseller* are evidently marks of the same idea, but yet the one has the sign of the possessive ('s), which the other has not. As far as the possessive case (so called) is concerned, it is in most instances awkward to add any explanatory word to it; and the sentence runs much more smoothly if we use the preposition *of*; thus, 'I called at the shop of Smith the bookseller,' where both words are obviously in the objective.

1. Your friend, *him* whom you introduced to me yesterday, very soon departed.
2. Why do you treat *Mary Ann* so harshly, *she* who has always been so affectionate?
3. The leader was taken, *him* who defied the law.
4. I am going to see my friends in the country; *they* whom we met at the ferry.

Rule VII.—The Verb To Be.

The verb *To Be* has the same case after it as it has before it: thus, '*Alfred* was a good king.' Here the word *king*, coming after the verb *was*, is in the nominative, because it is descriptive of *Alfred*, the subject of the sentence. 'She, supposing *him* to be the gardener, saith unto him.' Here *gardener* is to be considered in the objective, because *him*, going before the verb *to be*, is in the objective, governed by the verb *supposing*.

It requires very little penetration to perceive that this seventh rule is included in the sixth, for the verb *to be* does nothing more, in such cases, than mark that the two nouns between which it is put are different names for the same thing. On this subject Mr Mill, in his *Analysis*, Vol. i. p. 117, reasons with his usual acuteness. In showing how the name of a class comes to be used for the name of an individual, he says, 'I have the name of the individual, *John*, and the name of the class, *man*; and I can set down my two names, *John, man*, in juxtaposition. But this is not sufficient to effect the communication I desire—namely, that the word *man* is a mark of the same idea of which *John* is a mark, and a mark of other ideas along with it; those, to wit, of which James, Thomas, &c. are marks. To complete my contrivance, I invent a mark which, placed between my marks *John* and *man*, fixes the idea I mean to convey, that *man* is another mark to that idea of which *John* is a mark, while it is a mark of other ideas, of which James, Thomas, &c. are marks. For this purpose, we use in English the mark *is*. By help of this, my object is immediately attained.'

Those capable of understanding this dissertation will immediately see the virtual identity of our sixth and seventh rules; but here, as in other cases, we have been anxious not to depart from the common doctrines; and the repetition of the rule, while it may be useful to some, can do harm to none.

1. You believed *it* to be *he*.
2. *It* was not *me* who said so.
3. *It* appeared to be *her* who carried on the business.
4. Though I was blamed, *it* could not have been *me*.

These we take to be the great leading principles on which the Syntax of the English language is founded, and by the thorough understanding of which, the student will be enabled to see the construction of almost any sentence. Many grammarians, some of whom—particularly Crombie and M'Culloch—we highly respect, have given many more; but we adhere to the decision of Dr Johnson, the dictator of English literature, who says, that 'our language has so little inflection or variety of terminations, that its construction neither requires nor admits many rules.'

A few miscellaneous remarks (we cannot dignify them with the name of rules) will conclude this part of our subject:—

1. Every adjective must qualify a noun, either expressed or understood: thus in the lines—

'Auspicious Hope! in thy sweet garden grow  
Wreaths for each toil, a charm for every wo.'

every adjective is immediately followed by its noun. But in this,

'Few shall part where many meet,'

the noun *men* is obviously understood.

We have already seen that *a* and *an* (commonly called the indefinite article) are identical in meaning; but there is this difference in their application, that *a* is prefixed to words beginning with the sound of a consonant, the long sound of *u*, and vowels sounding like *w*; and *an* to words which begin with the sound of a vowel. Thus we say, *a* man, but *an* ox; *a* house, but *an* hospital; *a* one-horse coach; *a* unicorn; *an* easterly wind, &c.

2. The exact import of the four words, *each*, *every*, *either*, and *neither*, which are known by the name of Distributive Adjectives, ought to be carefully attended to, and, from their very meaning, it will appear that they must always be joined to a noun in the singular.

*Each* means the one and the other of two: thus Cowper, in his ode, 'The Lily and the Rose,' says properly—

'Until a third [flower] surpasses you both,  
Let each be deemed a queen.'

*Every* refers to any number more than two, considered individually: thus Byron, referring to the unfortunate separation of himself and Lady Byron, says—

'Both shall live, but every morrow  
Wakes us from a widowed bed.'

*Either* means the one or the other of two; *neither*, not either, not the one nor the other of two. The use of both words is seen in these lines—

——— 'Lepidus flatters both,  
Of both is flattered; but he neither loves,  
Nor either cares for him.'—SHAKESPEARE.

Milton makes a wrong use of *either* in these lines—

——— 'She was cheered,  
But silently a gentle tear let fall  
From either eye.'

3. In English, as already noticed, the adjective is not generally inflected for any purpose except to express degrees of comparison; but to this remark there are two exceptions. These are the Demonstrative Adjectives *this* and *that*, which have corresponding plurals, *these* and *those*: thus we say, *this* man, but *these* men; *that* map, but *those* maps.

4. It is not the office of an adjective to qualify either a verb or another adjective; this must be done by an adverb. We do not say, 'James reads good,' but 'James reads well.' 'I am myself *indifferent* honest,' should be, 'I am myself *indifferently* honest.'

'In general, no quality, when considered in concrete, or as qualifying some particular subject, can itself be conceived as the subject of any other quality, though, when considered in abstract, it may. No adjective, therefore, can qualify any other adjective. A *great good man*, means a man who is both *great* and *good*. Both the adjectives qualify the substantive: they do not qualify one another.'—Adam Smith.

That this is the *genius* of our language, admits not of reasonable doubt; but there are several exceptions. We speak of a thing as being of a *florid red* colour, and of iron as being *red hot*. We say, 'a *great many* were present;' 'the doors were *wide open*;' Byron speaks of the '*pale blue* sky;' in all which cases it is quite clear that the first adjective in some degree modifies the second. Whether this idiom is capable of being *metaphysically* defended against the reasoning of Smith, or whether such expressions are to be regarded as, to use the words of Johnson, 'spots impressed so deep in the English language, that criticism can never wash them away,' is a question into the discussion of which we shall not enter. About the *authority* of the expressions there can be no dispute.

It was already pointed out that certain adjectives, from their very nature, do not admit of comparison; and it should now be observed that, for the same reason, many of them, such as *universal*, *omnipotent*, and others, whose signification cannot be increased, ought not to be qualified by any adverb.

5. Tautological expressions ought to be avoided, and no word should be introduced into a sentence which has not some distinct function to perform.

'From whence came he?' should be, 'Whence came he?' because, as we already saw, *whence*, in itself, means '*from what place*.' Again, in the sentence, 'I doubt not but that he will come,' it is obvious, on a little reflection, that the idea intended would be completely conveyed by this form of expression—'I doubt not that he will come,' and the insertion of *but* serves no useful purpose. By reversing the sentence, this may be more obvious—'He will come, I doubt not that (*thing*).'

In this sentence, taken from Goldsmith's 'History of England'—'The New Englanders were determined to attack the royal forces as soon as *ever* they should march out of Boston'—the word *ever* is of no use, and consequently should be omitted.

Perhaps under the same remark might be included the following, which, however, from its extensive application, we shall keep separate.

6. Two negatives ought not to be used, unless affirmation is meant.

In this respect Bacon, Shakspeare, and Locke, and indeed all our early writers, frequently offend. Usage was in their times divided; but it has now become fixed, and that on the side of metaphysical propriety.

Bacon says—'The joys of parents are secret, and so are their griefs and fears; they cannot utter the one, *nor* will they *not* utter the other.' Shakspeare says—

'Be not too tame *neither*.'

And again,

'*Nor* do not saw the air too much.'

Goldsmith, too, has violated the idiom of the English tongue in this respect, although he has offended in good company: 'Never was a fleet more completely equipped, *nor never* had the nation more sanguine hopes of success.' *Never* should be *ever*. 'He is *not unjust*' is right, if we mean to express much the same idea as is conveyed by the words, 'He is just.' By some it is maintained that this mode of expression strengthens the affirmation, and certainly it may do so in spoken language; but in writing, it serves only to introduce ambiguity, and so ought to be avoided.

7. Certain conjunctions go in pairs: thus—both, and; either, or; neither, nor; though or although, yet; whether, or; so, that; not only or not merely, but also; so, as; as, as; such, as. Most of these words are conjunctions, but not all.

'I will *neither* come or send' is wrong; because *or* is not the correlative of *neither*: it ought to be, 'I will *either* come or send,' or, 'I will *neither* come nor send.'

8. Derivative words generally take the same prepositions after them as their primitives.

Goldsmith offends again in saying, 'Catiline was insatiable *of* wealth;' because we do not say to satiate

(the primitive of insatiable) a person of wealth, but *with* wealth.

9. Certain prepositions are appropriated to certain words and phrases.

We do not say, 'To have faith *to* a person,' but 'in a person;' 'To find difficulty *with* doing a thing,' but 'in doing it;' 'To differ *with* a person,' but '*from* a person.'

Such idiomatic expressions are only to be made familiar by an extensive and well-directed course of study; or, as Milton has it, 'by a well-continued and judicious conversing among pure authors.'

10. After the comparative degree, whether of adjectives or adverbs, and the adjective *other*, the conjunction *than* is used: thus, '*Better* is a little with righteousness, *than* great revenues without right;' 'This is none *other than* the house of God.' Shakspeare has offended against this idiom—

'The sun no *sooner* shall the mountains touch,  
But we will ship him hence.'

*But* ought to be *than*. 'Scarcely had Austria been crushed, *than* it was announced,' &c.—GOLDSMITH. *Than* ought to be *when*.

11. The Perfect Participle, and not the Past Tense, is used after the verbs *have* and *be*.

This remark requires to be attended to in using irregular verbs, but in verbs that are regular, no mistake can arise, as both parts are the same. In nothing, we venture to remark, does defective scholarship sooner betray itself than in a wrong conjugation of the irregular verbs.

'They *had* from the beginning *began* to embrace opposite systems.'—GOLDSMITH. *Began* ought to be *begun*.

'You must not think  
That we are made of stuff so flat and dull,  
That we can let our beard be *shook* with danger.'

—SHAKSPEARE.

*Shook* should be *shaken*.

12. Adverbs ought to be placed so as to leave no doubt what word is affected by them.

'The negroes are to appear at church *only* in boots.' By this position of *only*, it appears that the negroes were not to come to church unless 'in boots,' or with nothing else but boots; but the meaning intended was, that they should appear at church, and nowhere else, in boots. The sentence should therefore have stood thus:—'The negroes are to appear *only* at church in boots.' 'Pompey played a despicable part *enough* betwixt them.' *Enough* ought to be immediately after *despicable*. 'Cæsar so turned the fate of the day, that the barbarians were *almost* cut off to a man.' It ought to be, 'were cut off *almost* to a man.'

EXERCISES.

To all these remarks we shall subjoin a few miscellaneous examples, on which the student may exercise himself. We shall refer to the Rule or Remark violated as we go on.

1. Are either of us to blame? (Rule I. Remark 2.)
2. These kind of things give most satisfaction. (Rule I. Remark 3.)
3. I acted in compliance to his request. (Remarks 8 and 9.)
4. Let such teach others who themselves excel.—POPE. (Remark 7.)
5. These new divines offered salvation upon easier terms, by substituting practice to belief, and a man's own efforts to vicarious satisfaction.—Aiken's *Letters*. (Remark 9.)
6. There is nothing more please us as to have our performances praised. (Remark 10.)
7. Antony led the way direct to Italy. (Remark 4.)
8. Neither of them appealed to impotent laws which could afford them no protection.—ROBERTSON. (Rule IV. Remark 2.)
9. It is wonderful how preposterous the affairs of this world are managed.—FRANKLIN. (Remark 4.)
10. During the rest of his consular year, Bibulus could only escape outrage by not only avoiding all assemblies of the people, but every solemn and important meeting of the senate.—*History of Rome, Cabinet Cyclopædia*. (Remark 12.)

11. I never did repent for doing good,  
Nor shall not now.—SHAKSPEARE. (Remarks 6 and 9.)
12. The wisest princes need not think it any diminution to their greatness, or derogation to their sufficiency, to rely upon counsel.—BACON'S *Essays*. (Remark 9.)
13. The hostilities which twice interrupted the progress of the community, neither seemed to originate in any imperative claim of national honour or advantage.—WADE'S *British History*. (Remarks 13 and 7.)
14. It was observed to me, that in this country no man who is able to work need go superfluous to bed. This far he stated the fact.—COMBE'S *Notes on America*. (Rule V. Remark 4.)
15. When a nation forms a government, it is not wisdom, but power, which they place in the hands of the magistrate.—ROBERT HALL. (Rule IV.)
16. The leaders of the fleet and the army began mutually to accuse each other.—GOLDSMITH. (Remark 5.)
17. Royal proclamations continued as omnipotent as in the preceding reign.—WADE.
18. There have been three riots in England of late, each of which have been levelled against dissenters.—ROBERT HALL. (Remark 2.)

The student should now be so familiar with the *Rules of Syntax*, which are nothing but generalised facts regarding the customary modes of uniting words and sentences together, that he will be able to commit his thoughts to appropriate language; that is, such as shall convey to others the exact meaning he has in his own mind. To do this, however, not merely with accuracy, but also taste, besides attending to the rules of syntax, he must take care, first, that all the words he uses belong to the English tongue; and secondly, that they be employed in their usual and recognised acceptation.

A word *not English* is termed a *barbarism*, and when used in a sense different from its established one, an *impropriety*; both should be equally avoided, either in writing or speaking.

PUNCTUATION.

Punctuation, or the insertion of *points* in written language, is usually considered a part of grammar, and a knowledge of its principles is desirable for correct literary composition. The introduction of points is said to be useful to mark places at which a pause of a lesser or greater length should be made in reading. This definition is not altogether wrong, but punctuation has much higher objects in view. Points are necessary for marking the parts or sections into which sentences and paragraphs are divided, so that the exact meaning or sense may be apprehended, and perfect regularity preserved. The real use of points, therefore, is to cut off and separate single words, or groups of words, from each other. Sometimes the separation need only be slight, and for this the point called the *comma* (,) is sufficient. For instance, 'Providence has, I think, displayed a tenderness for mankind.' Here there is a comma before and after 'I think,' because these two words express something thrust into the sentence, which should be kept in some measure distinct. The *semicolon* (;) is used to mark a more perfect separation of words. In general, it cuts a sentence into two or more parts, one of which has a reference to the other. Thus, 'Economy is no disgrace; for it is better to live on a little than to outlive a great deal.' Here the sentence is in two sections, the *semicolon* marking the boundary of separation. The *colon* (:) signifies a still wider separation in the words of a sentence; but its qualifications are so indistinct, and so liable to misconception, that in practice it is now almost entirely disused, and the *period* or full stop (.) is employed in its stead.

The other marks used in written language are as follows:—The *mark of interrogation* (?), which is put after words asking a question; the *mark of admiration* (!), put after any exclamation of surprise, lamentation, or scorn; the *dash* (—), which is sometimes employed instead of a semicolon, or for any kindred purpose; and the *parenthesis* ( ), for enclosing a word or portion of a sentence foreign to the tenor of the

## ENGLISH GRAMMAR.

sense. Good writers endeavour to avoid requiring either parenthetic marks or dashes, both of which indicate irregularities of thought and expression.

### CONCLUSION.

We have now explained the Etymology and Syntax of the English tongue, as far as our limits permit; and in drawing to a close, we may be allowed to impress on our readers the value of the science which we have been endeavouring to expound. If they have intelligently gone along with us in our various remarks, they will not be surprised when we assert that this department of human knowledge, if skilfully cultivated, will be productive of very valuable results. To understand the grammar of a sentence, is nothing more or less than to understand its sense, and to see clearly how its various parts are connected; while in learning to recognise the different modifications that words undergo, and the different arrangements of which they are susceptible, to express difference of thought, we have exercised many of the mental faculties, and in so far laid the foundation of what is much wanted—a just system of Logic.

The sources whence the student will derive effectual aid in the prosecution of this interesting subject, we have already pointed out incidentally; but let no one lament too much though he should not have access to them. Rather let him, by additional thought on his own part, make up for the deficiency, and he may rest assured that, by accustoming himself to mark the different modes of expression he meets with in reputable authors, a *system of grammar will evolve itself*, which will be all the more valued—if we may not say valuable—that it has been wrought out by his own exertions, and not received by tradition or passively from the hands of another. Following this plan, the real method of induction, he will either reproduce the rules which we have set before him, or else see their erroneousess. So that, in either case, we shall deserve well of him; for, if we are right in anything, we shall have served as a guide to him; and in those points where we have erred, we shall have put him on the way to find out our errors. We know very well that the pupil cannot see with our eyes, and we have therefore only endeavoured to direct his attention to such objects as he may see with his own. So far as he sees, he should believe, and no farther. To dogmatise is the method of a grammarist, but our ambition has been to act the part of a philosophical grammarian, and, as such, we cannot conclude without warning our readers never to forget that words in themselves are nothing, and that they are only valuable in so far as they are the symbols of ideas. Beautifully and justly has Johnson said, 'Words are the daughters of earth, and things only are the sons of heaven.' Language is but a vehicle of thought, or, at best, its instrument, and to view it as an 'end unto itself,' is the vain humour of a pedant. Let none be so taken up with words as to forget solid things.

### COMMON ERRORS CORRECTED.

The remaining space of the present sheet could scarcely, we think, be better employed than in enumerating some examples of the most common errors in the pronunciation and selection of words. In every part of the country there are some peculiar vices of speech, which have been handed down from one generation to another, and are generally so inveterate in most minds, from the effect of early habit, that no cultivation which the mind may receive in mature life altogether obliterates them. For any one who has occasion to mix in refined society to be thus liable every moment to the use of some barbarism of speech, is a misfortune of some magnitude; for nothing tends so much to convey a mean impression of his education and habits of life. The most beautiful young female, who, silent, appears a kind of divinity, is reduced at once to common earth when we hear a few inellegant

words fall from her mouth. Coleridge somewhere tells that he was once much prepossessed in favour of an individual whom he met at a dinner-table, and who appeared a dignified and respectable person, until, some kind of fruit being introduced, he heard him exclaim, 'Oh, them's the jockies for me!' Words are the exponents of conditions of mind, and when mean ones are used, we unavoidably suppose the condition of mind to be mean.

### ERRORS IN PRONUNCIATION.

The interchange of *w* for *v*, and *v* for *w*, and the putting of the sound of *h* before words where it is inappropriate, and taking it away where it ought to be. *Examples*—Will you wait to get some wine and victuals! An 'ard-boiled hegg.

The sound *k* instead of *g* at the ends of words. *Examples*—Somethink, nothink.

The addition of *r* at the ends of words ending in vowels. *Examples*—Idear, windor, Elizar.

Changing the termination *en, ain, or eign, into ing*; as garding for garden, founting for fountain, sovering for sovereign, and the like.

### UNGRAMMATICAL FORMS.

Between you and I, there is a great want of conscientiousness in most partisans. *Correction*—Between you and me, &c.

I am not so proud as him. *Cor.*—As he.

You will do it better than her. *Cor.*—Than she.

May thou as well as me be meek, patient, and forgiving. *Cor.*—As well as I, &c.

While the house was being built. *Cor.*—While the house was in the course of being built.

He don't go to town to-day. *Cor.*—He does not go to town to-day.

I rather think he is out of town. *Cor.*—I believe he is out of town.

I had better go myself. *Cor.*—It were better that I should go myself.

I had oblige to go. *Cor.*—I was obliged to go.

John is tall in comparison to James. *Cor.*—John is tall in comparison with James.

He is a very rising man. *Cor.*—He is rising very rapidly.

She readied a dish for us. *Cor.*—She cooked, or prepared, a dish for us.

She was a superior woman, or, She was a most superior woman. *Cor.*—Superior can only be used with regard to something else which is at the same time expressed: thus, She was a woman much superior to the generality of her sex.

This is better nor that. *Cor.*—This is better than that.

Short-lived, long-lived. *Cor.*—Short-lived, long-lived.

The then Earl of Winchelsea; the then Mrs Bennet. *Cor.*—The Earl of Winchelsea of that time; the Mrs Bennet then living.

He lays asleep in the cabin. *Cor.*—He lies asleep in the cabin.

His health was drank. *Cor.*—His health was drunk.

The dinner was all eat up. *Cor.*—The dinner was all eaten up.

I went to table and eat very heartily. *Cor.*—I went to table and ate very heartily.

A couple of shillings. *Cor.*—Couple can only be properly applied to objects in connection; as, a married couple, a couple of pointers.

John, James, and Robert, were sober workmen, the latter particularly so. *Cor.*—The last particularly so (the objects enumerated being more than two).

Ask at him. *Cor.*—Ask him.

The 'Manchester Guardian' is a well-advertised paper—meaning a paper which usually contains many advertisements. *Cor.*—The 'Manchester Guardian' usually contains many advertisements, or—enjoys a large share of the patronage of advertisers.

I could not give him credit, without he changes his

behaviour. *Cor.*—I could not give him credit, unless he changes his behaviour.

I will go, *except* I should be ill. *Cor.*—Unless I should be ill.

I saw them all, *unless* two or three. *Cor.*—I saw them all, *except* two or three.

I took some cream *into* a bowl. *Cor.*—I took some cream *in* a bowl.

I am going *for* to do it. *Cor.*—I am going to do it.

He was a devoted *antiquarian* all his days. *Cor.*—He was a devoted antiquary all his days. (*Antiquarian* is the adjective.)

James is going to be a *medical* man. *Cor.*—James is going to be a physician, surgeon, or medical practitioner.

He is *oftener* wrong than right. *Cor.*—He is more frequently wrong than right.

I have *no right* to pay this tax. I have *no right* to be distressed by that man's conduct. *Cor.*—I am under no obligation to pay this tax. I am not obliged to suffer from that man's conduct.

You will be *necessitated* to submit. *Cor.*—You will be obliged to submit.

He is *not intending* to purchase it. *Cor.*—He does not intend to purchase it.

Don't talk of *those* sort of things to me. *Cor.*—Don't talk of that sort of things to me. *Sort of things* is a mean and objectionable expression. 'Things of that kind' is more elegant, as well as correct.

The castle is seated by the Garonne. *Cor.*—The castle is seated beside the Garonne.

Lord Byron was born *at* London. There have been destructive fires *at* Edinburgh. *Cor.*—Lord Byron was born in London. There have been destructive fires in Edinburgh. (*At* is only proper with respect to a small town.)

I met him *on* the street. *Cor.*—I met him in the street.

I don't know, but I will inquire *at* my friend. *Cor.*—Of my friend.

I was *calling for* you yesterday. *Cor.*—On you yesterday.

Oh, I *will* fall, and nobody *shall* help me. *Cor.*—Oh, I shall fall, and nobody will help me.

I have been to London, and am now going *for* Liverpool. *Cor.*—I have been in London, and am now going to Liverpool.

He was married *on* Miss Edmonstone. *Cor.*—He was married to Miss Edmonstone.

They were some distance from home when the accident happened. *Cor.*—At some distance, &c.

He lives *opposite* the Royal Exchange. *Cor.*—*Opposite* to, &c.

Pray, sit *into* the fire. *Cor.*—Pray, sit near the fire. The performance was approved *of* by all who understood it. *Cor.*—The performance was approved by all.

They attacked Northumberland's house, whom they put to death. *Cor.*—They attacked the house of Northumberland (or the Duke of Northumberland), whom they put to death.

It is true what he says, but it is not applicable to the point. *Cor.*—What he says is true, &c.

Together with the national debt, the greatest national advantages are *also* transmitted to succeeding generations. *Cor.*—*Also* is superfluous.

Falling in his effort, he *again* repeated it. *Cor.*—*Again* is superfluous.

He is *noway* thy inferior, and in this instance is *no ways* to blame. *Cor.*—He is in *nowise* thy inferior, and in this instance is not at all to blame.

It is *neither more nor less than* medicine in disguise. *Cor.*—It is simply medicine in disguise.

The master never *challenged* him for stealing. *Cor.*—The master never reproved him for stealing.

He charged me with want of resolution, in which he was greatly mistaken. *Cor.*—He charged me with want of resolution, but in this censure he was greatly mistaken.

He gave her a beautiful book *in* a present. *Cor.*—

He gave her a beautiful book *as* a present: (or better) He presented her with, or made her a present of, a beautiful book.

No *less* than two hundred scholars have been educated in that school. *Cor.*—No fewer, &c.

There was a *quantity* of people present. *Cor.*—There was a number of people present.

It is above a year since the time that I left school. *Cor.*—It is more than a year since I left school.

He felt the *peculiar*ness of his situation. *Cor.*—He felt the peculiarity of his situation. In like manner *delicacy* should be preferred to *delicateness*, *incapability* to *incapableness*, &c.

He was guilty of such atrocious conduct, that he was deserted by his friends for good and all. *Cor.*—He was guilty of conduct so atrocious, that he was entirely deserted by his friends.

OBSCURE, AWKWARD, AND MEAN FORMS.

I had *as lief* do it myself as persuade another to do it. *Cor.*—I would as readily, &c.

He convinced his opponent by *sheer dint* of argument. *Cor.*—Entirely by force of argument.

He is *not a whit* better than those whom he so liberally condemns. *Cor.*—He is not in any degree, &c.

He stands *upon the bond*, and will not abate a  *jot* of his claim. *Cor.*—He insists on the strict terms of the bond, and will not in the least abate his claim.

Good satin, I *take* it, is considerably superior to common silk. *Cor.*—I presume, &c.

You have *no call* to do it. *Cor.*—You have no occasion to do it.

I have *no right* to pay. *Cor.*—I am not bound to pay.

Politics too often *sets men by the ears*. When they *come to words*, and *fall out*, reason is generally lost sight of. I should not wonder but on this occasion there might be *broken heads going*. *Cor.*—Politics too often cause quarrels. When men enter into controversy, and differ violently, reason is generally lost sight of. I should not wonder but on this occasion they might commit some violence on each other.

We shall have a *regular break-up* in the ministry. *Cor.*—We shall have a dissolution of the ministry.

He was very dexterous in *smelling out* the designs of his neighbours. *Cor.*—In penetrating, &c.

He is a *thorough-paced* knave. *Cor.*—He is a great knave.

*Heretofore* Hannibal had carried all before him; *wherefore* he had become very proud, listening to no advice *whatsoever*; *whereas* Scipio invariably took counsel from the most sagacious of his officers.—The words in *Italics* are all obsolete and objectionable.

He *wist* not what to do. *Cor.*—He knew not what to do.

He little *wots* of the storm that is brewing. *Cor.*—He is not aware, &c.

*Topsy-turvy*, *pell-mell*, *hurly-burly*, having a *month's mind* for a thing, *currying favour* with a person, *dancing attendances* on customers, *get into a scrape*, *come to the scratch*, *flare up*, *fork out*, *walk into him*, *kick up a row*, *raise a rumpus*, and the like—All objectionable from their meanness.

We are *at one* on the slave question. I happen to have a little leisure *upon my hands*. He might have perceived it with *half an eye*.

My father *left* this morning by the mail. *Cor.*—My father went away this morning, &c. 'When are you to *leave*?' is in like manner vicious. The place or thing left should always be stated.

Slang phrases of all kinds should be received warily. The least objectionable are those which merely suggest comical ideas; those which tend to present light and jocular views of moral error are particularly detestable.

It will be the aim of a well-bred and judicious person to make his discourse neither too nice and formal, nor too loose and homely, but, as far as possible, to preserve a medium between the select language employed in literature, and the familiar, and perhaps temporary, phraseology which prevails in ordinary society.

## ARITHMETIC—ALGEBRA.

In the present and succeeding sheet, an attempt is made to convey to the comparatively unlearned mind some knowledge of Mathematical science, both as regards measurement by numbers (ARITHMETIC) and measurement of dimensions (GEOMETRY). The sketch we offer of each is necessarily brief and imperfect; but our end will be gained if we afford that amount of information on the subject which is generally possessed by persons of moderately well-cultivated intellect.

A recognition of the value of *numbers* is coeval with the dawn of mental cultivation in every community; but considerable progress must be made before methods of reckoning are reduced to a regular system, and a notation adopted to express large or complex quantities. An inability to reckon beyond a few numbers is always a proof of mental obscurity; and in this state various savage nations have been discovered by travellers. Some are found to be able to count as far as five, the digits of the hand most likely familiarising them with that number; but any further quantity is either said to consist of so many fives, or is expressed by the more convenient phrase, 'a great many.' Among the North American Indians, any great number which the mind is incapable of distinctly recognising and naming is figuratively described by comparing it to the leaves of the forest; and in the same manner the untutored Negro of Africa would define any quantity of vast amount by pointing to a handful of sand of the desert.

On the first advance of any early people towards civilisation, it would be found impossible to give a separate name to each separate number which they had occasion to describe. It would therefore be necessary to consider large numbers as only multiplications of certain smaller ones, and to name them accordingly. This is no doubt what gave rise to classes of numbers, which are different in different countries. For instance, the Chinese count by *twos*; the ancient Mexicans reckoned by *fours*. Some counted by *fives*, a number which the fingers would always be ready to suggest. The Hebrews, from an early period, reckoned by *tens*, which would also be an obvious mode, from the number of the fingers of the two hands, as well as of the toes of the two feet. The Greeks adopted this method; from the Greeks it came to the Romans, and by them was spread over a large part of the world.

### NOTATION.

Notation is the method of expressing numbers by means of certain *signs* or figures. The representation of numbers by written signs is an art generally believed to have taken its rise after the formation of alphabets. One of the earliest sets of written signs of numbers of which we have any notice, is certainly the series of letters of the Hebrew alphabet which was used by that people—Aleph, beth, gimel, dalet, he, vau, zain, cheth, teth, standing respectively for the numbers one, two, three, four, five, six, seven, eight, nine. The Greeks directly adopted this plan from the Hebrews, forming their numbers thus:—1 alpha, 2 beta, 3 gamma, 4 delta, 5 epsilon—here, having no letter corresponding with the Hebrew *vau*, they put in the words *επιπεντα βαυ* to denote six; after which they proceeded with 7 zeta, 8 eta, &c. Before adopting this plan, they had indicated one by iota  $\iota$ , probably because it was the smallest of their letters; five by  $\Pi$  (P), being the first letter of *πεντε*, five; ten by  $\Delta$  (D), being the initial of *δεκα*, ten. After having for some time adopted the Hebrew mode, they divided their alphabet into three classes: the first ten letters expressing the numbers from one to ten; while twenty, thirty, forty, and so on up to a hundred, were signified by the next nine,

ninety being expressed by a figure formed on purpose, and resembling the Arabic 5 inverted. The remaining seven letters expressed respectively 200, 300, 400, 500, 600, 700, 800; and for 900 there was another inverted figure. Larger numbers were represented by letters accented in various ways.

The Romans, from an early period, had a method of expressing numbers, which seems to have been at first independent of the alphabet. The following intelligible account of it has been given by Professor Playfair:—'To denote one, a simple upright stroke was assumed |; and the repetition of this expressed two, three, &c. Two cross strokes X marked the next step in the scale of numeration, or ten; and that symbol was repeated to signify twenty, thirty, &c. Three strokes, or an open square  $\square$ , were employed to denote the hundred, or the third stage of numeration; and four interwoven strokes M, sometimes incurved  $\mathcal{M}$ , or even divided CI $\mathcal{O}$ , expressed a thousand. Such are all the characters absolutely required in a very limited system of numeration. The necessary repetition of them, however, as often occasionally as nine times, was soon found to be tedious and perplexing. Reduced or curtailed marks were therefore employed to express the intermediate multiples of five; and this improvement must have taken place at a very early period. Thus five itself was denoted by the upper half V, and sometimes the under half  $\wedge$ , of the character X for ten;  $\perp$ , or the half of  $\square$ , the mark for a hundred, came to represent fifty; and the incurved symbol  $\mathcal{M}$ , or CI $\mathcal{O}$ , for a thousand, was split into I $\mathcal{O}$ , to express five hundred.

These important contractions having been adopted, another convenient abbreviation was introduced. To avoid the frequent repetition of a mark, it was prefixed to the principal character, and denoted the effect by counting backwards. Thus instead of four strokes, it seemed preferable to write  $\text{IV}$ ; for eight and nine the symbols were  $\text{IIX}$  and  $\text{IIX}$ ; and ninety was expressed by  $\text{XC}$ . This mode of reckoning by the defect was peculiar to the Romans, and has evidently affected the composition of their numerical terms. Instead of *octodecem* [eight and ten—for eighteen], and *novemdecem* [nine and ten—for nineteen], it was held more elegant, in the Latin language, to use *undeviginti* [one from twenty], and *duodeviginti* [two from twenty].

But the alphabetic characters now lent their aid to numeration. The uniform broad strokes were dismissed, and those letters which most resembled the several combinations were adopted in their place. The marks for one, five, ten, and fifty, were respectively supplied by the letters I, V, X, and L. The symbol for a hundred was aptly denoted by C, which had originally a square shape, and happened, besides, to be the initial of the very word *centum*. The letter D was very generally assumed as a near approximation to the symbol for five hundred; and M not only represented the angular character for a thousand, but was likewise, though perhaps accidentally, the first letter of the word *mille*.—*Edin. Rev.* No. xviii, p. 193.

The Hebrew, improved Grecian, and Roman numerals were perhaps sufficient to express any single number with tolerable precision; but it is easy to see that they must have been nearly unfitted for use in the processes of arithmetic. The Greeks certainly contrived to overcome many obstacles in the business of calculation, and even could express fractions—though, from a practice of adding from left to right, and ignorance of the plan of *carrying* tens to the higher places, their problems were at all times awkward and complicated. The Romans, however, careless of old inconveniences, were still more awkwardly situated than

the Greeks. Let any reader just suppose, for instance, even so simple a question as the amount of XLVIII added to XXXIV! It is evident that placing the figures below each other, as we do with the Arabic numerals, would serve little to facilitate such a calculation. In fact, the Romans were obliged, where mental calculation would not serve, to resort to a mechanical process for performing problems in arithmetic. A box of pebbles called *loculus*, and a board called *abacus*, constituted their means of calculation; and of these every schoolboy, and many other persons, possessed a set. The word calculation claims no higher descent than from *calculus*, a stone or pebble. The board was divided from the right to the left hand by upright columns, on which the pebbles were placed, to denote units, tens, hundreds, thousands, &c. The labour of counting and arranging the pebbles was afterwards sensibly abridged by drawing across the board a horizontal line, above which each single pebble had the power of five. In the progress of luxury, *tali*, or dices made of ivory, were used instead of pebbles; and afterwards the whole system was made more convenient by substituting beads strung on parallel threads, or pegs stuck along grooves; methods of calculation still used in Russia and China, and found convenient in certain departments of Roman Catholic devotion, and in several familiar games in more civilised countries. With such instruments, problems in addition and subtraction would not be very difficult; but those in multiplication and division, not to speak of the more compound rules, must have been extremely tedious and irksome. So disagreeable, indeed, was the whole labour, that the Romans generally left it to slaves and professional calculators.

The numerals now in use, with the mode of causing them by peculiar situation to express any number, and whereby the processes of arithmetic have been rendered so highly convenient, have heretofore been supposed to be of Indian origin, transmitted through the Persians to the Arabs, and by them introduced into Europe in the tenth century, when the Moors invaded and became masters of Spain. Such, in reality, appears to have been in a great measure the true history of the transmission of these numerals; but as it has been lately found that the ancient hieroglyphical inscriptions of Egypt contain several of them, learned men are now agreed that they originated in that early seat of knowledge, between which and India there exist more points of resemblance, and more traces of intercourse, than is generally supposed. In the eleventh century, Gerbert, a Benedictine monk of Fleury, and who afterwards ascended the papal throne under the designation of Sylvester II., travelled into Spain, and studied for several years the sciences there cultivated by the Moors. Among other acquisitions, he gained from that singular people a knowledge of what are now called the *Arabic numerals*, and of the mode of arithmetic founded on them, which he forthwith disclosed to the Christian world, by whom at first his learning caused him to be accused of an alliance with evil spirits. The knowledge of this new arithmetic was about the same time extended, in consequence of the intercourse which the Crusaders opened between Europe and the East. For a long time, however, it made a very slow and obscure progress. The characters themselves appear to have been long considered in Europe as dark and mysterious. Deriving their whole efficacy from the use made of the cipher, so called from the Arabic word *tsaphara*, denoting *empty* or *void*, this term came afterwards to express, in general, any secret mark. Hence in more troublous times than the present, a mode of writing was practised, by means of marks previously concerted, and called *writing in cipher*. The Arabic characters occur in some arithmetical tracts composed in England during the thirteenth and fourteenth centuries, particularly in a work by John of Halifax, or De Sacrobosco; but another century elapsed before they were generally adopted. They do not appear to have settled into their present forms till about the time of the invention of printing.

It would be impossible to calculate, even by their own transcendent powers, the service which the Arabic numerals have rendered to mankind.

NUMERATION.

Numeration is the art of *numbering*—that is, of expressing any number in words. The Arabic numerical signs now generally in use take the following well-known forms:—1, 2, 3, 4, 5, 6, 7, 8, 9, 0. The first nine of these, called *digits* or digital numbers, represent, each, one of the numbers between *one* and *nine*, and when thus employed to represent single numbers, they are considered as *units*. The last (0), called a *nought*, nothing, or cipher, is, in reality, taken by itself, expressive of an absence of number, or nothing; but, in connection with other numbers, it becomes expressive of number in a very remarkable manner.

The valuable peculiarity of the Arabic notation is the enlargement and variety of values which can be given to the figures by associating them. The number ten is expressed by the 1 and 0 put together—thus 10; and all the numbers from this up to a hundred can be expressed in like manner by the association of two figures—thus, twenty, 20; thirty, 30; eighty-five, 85; ninety-nine, 99. These are called decimal numbers, from *decem*, Latin for ten. The numbers between a hundred and nine hundred and ninety-nine inclusive, are in like manner expressed by three figures—thus, a hundred, 100; five hundred, 500; eight hundred and eighty-five, 885; nine hundred and ninety-nine, 999. Four figures express thousands; five, tens of thousands; six, hundreds of thousands; seven, millions; and so forth. Each figure, in short, put to the left hand of another, or of several others, multiplies that one or more numbers by ten. Or if to any set of figures a nought (0) be added towards the right hand, that addition multiplies the number by ten; thus 999, with 0 added, becomes 9990, nine thousand nine hundred and ninety. Thus it will be seen that, in notation, the *rank* or place of any figure in a number is what determines the value which it bears. The figure third from the right hand is always one of the hundreds; that which stands seventh always expresses millions;

and so on. And whenever a new figure is added towards the right, each of the former set is made to express ten times its former value. A large number is thus expressed in the Arabic numerals, every set of three from the right to the left hand being separated by a comma for the sake of distinctness.

The above number is therefore one thousand two hundred and thirty-four millions, five hundred and sixty-seven thousand, eight hundred and ninety. Higher numbers are expressed differently in France and England. In the former country, the tenth figure expresses billions, from which there is an advance to tens of billions, hundreds of billions, trillions, &c. In our country, the eleventh figure expresses ten thousands of millions, the next hundreds of thousands of millions, the next billions, &c. The two methods will be clearly apprehended from the following arrangement:—

ENGLISH.	FRENCH.
Units.	Units.
Tens.	Tens.
Hundreds.	Hundreds.
Thousands.	Thousands.
Tens of thousands.	Tens of thousands.
Hundreds of thousands.	Hundreds of thousands.
Millions.	Millions.
Tens of millions.	Tens of millions.
Hundreds of millions.	Hundreds of millions.
Thousands of millions.	Billions.
Ten thousands of millions.	Tens of billions.
Hundreds of thousands of millions.	Hundreds of billions.
Billions.	Trillions.
Tens of billions.	Tens of trillions.
Hundreds of billions.	Hundreds of trillions, &c.

## ARITHMETIC.

For practice in Notation and Numeration, the reader should write down large numbers alternately in words and figures; at first assisting himself by the use of commas, but gradually dispensing with these as he acquires facility and certainty of expression.

### SIMPLE OR ABSTRACT NUMBERS.

There are four elementary departments in arithmetic—Addition, Multiplication, Subtraction, and Division.

#### Addition.

Addition is the adding or summing up of several numbers, for the purpose of finding their united amount. We add numbers together when we say, 1 and 1 make 2; 2 and 2 make 4; and so on. The method of writing numbers in Addition, is to place the figures under one another, so that units will stand under units, tens under tens, hundreds under hundreds, &c. Suppose we wish to add together the following numbers—27, 5, 536, 352, and 275; we range them in columns one under the other, as in the margin, and draw a line under the whole. Beginning at the lowest figure of the right-hand column, we say 5 and 2 are 7—7 and 6 are 13—13 and 5 are 18—18 and 7 are 25; that is, 2 tens and 5 units. We now write the 5 below the line of units, and carry or add the 2 tens, or 20, to the lowest figure of the next column. In carrying this 20, we let the cipher go, it being implied by the position or rank of the first figure, and take only the 2; we therefore proceed thus—2 and 7 are 9—9 and 5 are 14—14 and 3 are 17—17 and 2 are 19. Writing down the 9, we proceed with the third column, carrying 1, thus—1 and 2 are 3—3 and 3 are 6—6 and 5 are 11. No more figures remaining to be added, both these figures are now put down, and the amount or sum of them all is found to be 1195. Following this plan, any quantity of numbers may be summed up. Should the amount of any column be in three figures, still, only the last or right-hand figure is to be put down, and the other two carried to the next column. For example, if the amount of a column be 127, put down the 7 and carry the other two figures, which are 12; if it be 234, put down the 4 and carry 23.

For the sake of brevity, in literature, addition is often denoted by the figure of a cross, of this shape +. Thus, 7 + 6 means 7 added to 6; and in order to express the sum resulting, the sign =, which means equal to, is employed, as 7 + 6 = 13; that is, 7 and 6 are equal to 13. Again, 8 + 5 + 9 = 22.

#### Multiplication.

Multiplication is a short method of addition under certain circumstances. If we wish to ascertain the amount of twelve times the number 57, instead of setting down twelve rows of 57, and adding them together, we adopt a shorter plan, by which we come to the same conclusion. For ascertaining the amount of all simple numbers as far as 12 times 12, young persons commit to memory the following Multiplication Table, a knowledge of which is of great value, and saves much trouble in after life:—

1	2	3	4	5	6	7	8	9	10	11	12
2	4	6	8	10	12	14	16	18	20	22	24
3	6	9	12	15	18	21	24	27	30	33	36
4	8	12	16	20	24	28	32	36	40	44	48
5	10	15	20	25	30	35	40	45	50	55	60
6	12	18	24	30	36	42	48	54	60	66	72
7	14	21	28	35	42	49	56	63	70	77	84
8	16	24	32	40	48	56	64	72	80	88	96
9	18	27	36	45	54	63	72	81	90	99	108
10	20	30	40	50	60	70	80	90	100	110	120
11	22	33	44	55	66	77	88	99	110	121	132
12	24	36	48	60	72	84	96	108	120	132	144

This table is so well known, that it is almost superfluous to explain that, when any number in the top row is multiplied by any number in the left-hand side row, the amount is found in the compartment or square beneath the one and opposite the other. Thus, 2 times 2 are 4; 5 times 6 are 30; 12 times 12 are 144.

The multiplying of numbers beyond 12 times 12 is usually effected by a process of calculation in written figures. The rule is to write down the number to be multiplied, called the *multiplicand*; then place under it, on the right-hand side, the number which is to be the *multiplier*, and draw a line under them. For example, to find the amount of 9 times 27, we set down the figures thus—

$$\begin{array}{r} 27 \text{ (Multiplicand.)} \\ 9 \text{ (Multiplier.)} \\ \hline 243 \text{ (Product.)} \end{array}$$

Beginning with the right-hand figure, we say 9 times 7 are 63; and putting down 3, we carry 6, and say 9 times 2 are 18, and 6 which was carried makes 24; and writing down these figures next the 3, the product is found to be 243.

When the multiplier consists of two or more figures, place it so that its right-hand figure comes exactly under the right-hand figure of the multiplicand; for instance, to multiply 185742 by 5463, we proceed as here shown. Here the number is multiplied, first by the 4, the product of which being written down, we proceed to multiply by 3, and the amount produced is placed below the other, but one place farther to the left.

A line is then drawn, and the two products added together, bringing out the result of 185742. We may in this manner multiply by three, four, five, or any number of figures, always placing the product of one figure below the other, but shifting a place farther to the left in each line. An example is here given in the multiplying of 76843 by 4563.

Multiplication is denoted by a cross of this shape ×: thus, 3 × 8 = 24, signifies, that by multiplying 3 by 8, the product is 24. A number which is produced by the multiplication of two other numbers, as 30 by 5 and 6, leaving nothing over, is called a *composite* number. The 5 and 6, called the *factors* (that is, workers or agents), are said to be the *component parts* of 30, and 30 is also said to be a multiple of either of these numbers. The equal parts into which a number can be reduced—as the twos in 30—are called its aliquot parts. A number which cannot be produced by the multiplication of two other numbers, is called a *prime* number. When the multiplicand and multiplier are the same—that is, when a number is multiplied by itself once—the product is called the *square* of that number: 144 is the square of 12.

#### Subtraction.

Subtraction is the deducting of a smaller number from a greater, to find what remains, or the difference between them. We subtract when we say, take 3 from 5, and 2 remains; 4 from 10, and 6 remains. To ascertain what remains, after taking 325 from 537, we proceed by writing the one under the other, as 325 here indicated, and then subtracting. Commencing at 5, the right-hand figure of the lower and smaller number, we say, 5 from 7, and 2 remains; setting down the 2, we say next, 2 from 3, and 1 remains; and setting down the 1, we say, 3 from 5, and 2 remains; total remainder, 212.

To subtract a number of a higher value, involving the *carrying* of figures and supplying of tens, we proceed as in the margin. Commencing as before, we find that 5 cannot be subtracted from 2, and therefore supply or lend 10 to the 2, making it 12; then we say, 5 from 12, and 7 remains. Setting down the 7, we take 1, being the decimal figure of the number which was borrowed, and give it to the 1, making it 2, and taking 2 from 3, we find that 1 remains.

Setting down the 1, we go to the 8, and finding it cannot be taken from the 4 above it, we lend 10 to the 4, making it 14, and then we say, 8 from 14, and 6 remains. In the same manner as before, adding the first figure of the borrowed number (1) to the 6, we say, 7 from 8, and 1 remains; thus the total remainder is found to be 1617. From these explanations, which apply to all calculations in subtraction, it will be observed, that when the upper figure is less than the figure directly under it, 10 is to be added, and for this one is carried or added to the next under figure.

Subtraction is denoted by a small horizontal line, thus — between two figures; as, for example,  $9 - 5 = 4$ , which means, 5 subtracted from 9, and 4 remains. Again,  $19 - 11 = 8$ ; that is, 11 taken from 19 leaves 8; or 19 diminished by 11, equal to 8.

Division.

Division is that process by which we discover how often one number may be contained in another, or by which we divide a given number into any proposed number of equal parts. By the aid of the Multiplication Table, we can ascertain without writing figures how many times any number is contained in another, as far as 144, or 12 times 12; beyond this point notation is employed. There are two modes of working questions in division—one long, and the other short. Let it be required to divide 69 by 3: according to 3)69 (23 the long method, we write the figures 69 as annexed, with a line at each side, and the divisor, or 3, on the left. The question is wrought out by examining how many times 3 is in 6, and finding it to be 2 times, we place 2 on the right side; then, placing 6 below 6, we draw a line and bring down the 9, and proceed with it in the same manner. The quotient is found to be 23. But we take a more difficult question—the division of 7958 by 6. In commencing, we find that there is only one 6 in 7, and 1 over; we therefore place the 6 below the 7, and subtract it, in order to bring out the 1. The 1 being written, we bring down the 9 to it, and this makes 19. There being 3 times 6 in 18, we place the 3 to the product (which in division is called the *quotient*—literally, How many times), and 18 below the 19, leaving 1 over as before. To this 1 we bring down the 5, and trying how many sixes there are in 15, it appears there are only 2. We place 2 to the quotient, and 12 below the 15. This leaves 3 over, and bringing down 8 to the 3, we have 38, in which there are 6 sixes. Six sixes make 36; therefore placing 6 to the quotient, and 36 below the 38, we find that there are 2 over. Here the account terminates, it being found that there are 1326 sixes in 7958, with a remainder of 2 over. In this question, 6 is called the *divisor*; the 7958 is the *dividend*, and 1326 is the *quotient*.

Skilful arithmeticians never adopt this long method of division; they pursue a plan of working out part of the question in the mind, called Short Division. They would, for example, treat the 6)7958 above question as here shown. The over 1326-2 number of 1 from the 7 is carried in the mind to the 9, making 19; the 1 from 19 is in the same manner carried to the 5; and the 3 from it is carried to the 8, leaving the overplus of 2.

Division is denoted by the following character  $\div$ ; thus  $75 \div 25$ , signifies that 75 is to be divided by 25. For example,  $240 \div 8 = 30$ .

By employing the signs or abbreviations above adverted to, any arithmetical operation may be very briefly stated; thus  $8 + 6 - 4 \times 3 \div 5 = 6$ .

These explanations conclude the subject of simple or abstract numbers. On the substructure of the few rules in Addition, Multiplication, Subtraction, and Division, which we have given, whether in reference to whole numbers or fractions, every kind of conventional

arithmetical is erected, because these rules are founded in immutable truths. Mankind may change their denominations of money, weights, and measures, but they can make no alteration in the doctrine of abstract numbers. That 2 and 2 are equal to 4, is a truth yesterday, to-day, and for ever; but as to how many pence are in a shilling, or how many inches in a foot, these are altogether matters of arbitrary arrangement, and the treatment of them forms an inferior department of arithmetical study, taking a different form in different countries; this *local* arithmetic, as we may call it, is comprehended in the term

COMPOUND NUMBERS OR QUANTITIES.

The calculation of the value of any number of articles, or a summation of values, in relation to money, would be comparatively simple if the scale of money were constructed on a principle of decimals, or advancing by tens—as, for example, 10 farthings 1 penny, 10 pence 1 shilling, 10 shillings 1 pound. By making both weights and measures on the same plan, as 16 ounces 1 pound, 10 pounds 1 stone, 10 stones 1 hundredweight; 10 inches 1 foot, 10 feet 1 yard, &c., ordinary calculations would be rendered exceedingly easy. Thus if an ounce cost 1d., a pound would cost 1s., and a hundredweight would cost 100s. or £10; or, reversing the question, if we were asked £10 per hundredweight for any article, we should know in an instant that it was at the rate of 1d. an ounce. In short, the greater number of arithmetical calculations would be accomplished by little more than a momentary reflection, without the aid of pen or pencil.

This very convenient system of decimal arithmetic is established in France and Belgium, and it is there carried to a most enviable degree of perfection: as, for example, in money reckoning, the *franc* (equal to our 10d.) is the standard coin of account, and is divided into 100 parts called *centimes*. There is an equal simplicity in the money reckoning of the North American Union, in which the dollar (equal to our 4s. 3d.) is divided into 100 centimes; but as weights and measures are not on the same decimal scale, the advantage is of comparatively small moment.

In the United Kingdom, the pound or sovereign is the standard in money. It consists of a series of inferior coins, advancing irregularly from a farthing upwards; as 2 farthings 1 halfpenny, 2 halfpence or 4 farthings 1 penny, 12 pence 1 shilling, 20 shillings 1 pound. While, therefore, the French compute values in money by francs and centimes, and the Americans by dollars and centimes, we compute by pounds, shillings, and pence; and to ascertain the value of irregular quantities in these irregular denominations of money, there is a complex set of rules to be obeyed; indeed, it may be said that the principal part of the time usually spent by youth at school on arithmetic, is consumed in learning to work questions in this arbitrary and local department of the science. We have only room to give a few examples in this species of computation.

L is the initial letter of the Latin word *libra*, a pound, and is used to denote pounds; s from the Latin word *solidus*, for shillings; and d from *denarius*, for pence: £ s. d. are therefore respectively placed over columns of pounds, shillings, and pence. The mark for a halfpenny is  $\frac{1}{2}$ , for a farthing  $\frac{1}{4}$ , and for three farthings  $\frac{3}{4}$ . To find the number of farthings, £5 pence, and shillings, in any number of pounds, we multiply by 20, which brings the pounds into shillings; next by 12, which brings the shillings into pence; and lastly, by 4, which brings the pence into farthings; as, for example, Required the number of farthings in £5—we proceed as in the margin. The result is observed to be 4800 farthings.

Compound Addition.

In ordinary transactions of business, and making up of accounts, Compound Addition—that is, the addition of monies—is principally required. In the margin is

## ARITHMETIC.

an account of sums to be reckoned up. The first thing done is to add together the halfpence and farthings in the right-hand side; and in doing so, we throw all into farthings. Thus, 2 and 1 are 3, and 3 are 6, and 2 are 8, and 2 are 10. Ten farthings are 2 pence, and 2 farthings, or one half-penny over. We set down  $\frac{1}{2}$  for the halfpenny, and carry the 2 to the pence column; this being added, we find there are 31 pence, which make 2 shillings and 7 pence. We write down the 7, and carry the 2 shillings to the shillings column; adding them to the under figure at the right-hand side, we reckon up thus—2 and 2 are 4, and 5 are 9, and 7 are 16, and 4 are 20, and 2 are 22; we put down 2 aside, and carrying 2 to the second row of the shillings column, we find on summing it up, that it amounts to 7; this 7 and the 2 set aside make 72 shillings—that is, £3, 12s.; 12, therefore, is written down under the shillings column, and the 3 pounds are carried to the pounds column, which is added up as in Simple Addition, making £320. Thus the sum-total is £320, 12s. 7 $\frac{1}{2}$ d. All accounts in Compound Addition referring to British money are performed in the same manner. We recommend young persons to acquire facility in adding; and it will save much time if they learn to sum up the columns by a glance of the eye, without naming the numbers; for instance, instead of saying 2 and 2 are 4, and 5 are 9, and 7 are 16, and 4 are 20, and 2 are 22, acquire the knack of summing the figures in the mind, thus—2, 4, 5, 9, 16, 20, 22.

### Compound Multiplication.

Questions in Compound Multiplication are determined in the following manner:—Having written down the number to be multiplied, place the multiplier under the lowest denomination, and proceed as in this example. We wish to multiply the sum of £37, 16s. 8 $\frac{1}{2}$ d. by 6. We begin by multiplying the farthings by the 6; this makes 18 farthings, or 4 $\frac{1}{2}$ d. Setting down the  $\frac{1}{2}$ , we carry the 4 to the pence, saying 6 times 8 are 48, and 4 are 52, which is equal to 4 shillings and 4 pence. Setting down the 4 pence, we carry the 4 shillings onward, and multiplying 16 by 6 find 96, which, added to the 4 shillings, gives 100. This is equal to £5, so we set down 0, and carry the 5 to the 57. The amount is 227. The answer of the question is therefore £227, 0s. 4 $\frac{1}{2}$ d.

### Compound Subtraction.

Compound Subtraction is performed as in the following question:—If we take £27, 17s. 8 $\frac{1}{2}$ d. from £36, 14s. 5 $\frac{1}{2}$ d., how much remains? The first thing we are called on to do, is to take 3 farthings from 2 farthings, or  $\frac{1}{4}$ d., and as this cannot be done, we borrow a penny, or 4 farthings, and adding these to the 2 farthings, we have 6. We now take 3 from 6, and find that 3 remains, which is therefore written down. It is now necessary to account for the borrowed penny, and a means of doing this would be to consider the pence of the upper line of figures as so much less, or 4d. instead of 5d. It is found, however, to be the most convenient plan to add 1 to the pence of the lower line, which comes to the same thing. Adding 1 to 8, in this case, we have 9 to subtract from 5. As this cannot be done, we borrow 1s., which is 12 pence, and adding that 12 to the 5 makes 17, from which taking 9, there will remain 8, which is placed under the pence. The borrowed 1s. is also repaid by adding 1 to the 17, making thus 18 to be taken from 14; but as we cannot do this either, we borrow £1, which is 20s. Adding 20s. to 14 makes 34; then 18 from 34 leaves 16. This is placed under the shillings, and 1 is carried to the lower amount of pounds, which are then subtracted as in Simple Subtraction; thus, 1 to 7 is 8, 8 from 6, cannot, but 8 from 16, there remains 8; carry 1 to 2 is 3,

and 3 from 3, nothing remains. Total sum remaining, £8, 16s. 8 $\frac{1}{2}$ d.

### Compound Division.

Compound Division is performed as follows:—We wish to divide £87, 14s. 9 $\frac{1}{2}$ d. into 7 equal parts. Dividing 87 by 7, as in Simple Division, the answer is 12, and 3 remain—that is, 3 pounds are over. We set down the 12 10 8 $\frac{1}{4}$ , and taking the 3 which is over, we reduce it to its equivalent in shillings, that is 60; we then add the 60 to 14, making 74, which being divided by 7 gives 10 shillings, and 4 shillings over. Setting down the 10, we carry forward the 4; 4 shillings are 48 pence, which, added to 9, makes 57. This divided by 7 gives 8 and 1 penny over; a penny is 4 farthings; add to these the 3 in the dividend, thus making 7; 7 divided by 7 gives 1, that is  $\frac{1}{4}$ d. The sum desired, then, is £12, 10s. 8 $\frac{1}{4}$ d.

If the divisor is a composite number—the product of two numbers individually not exceeding 12—we can divide first by one and then by the other, as follows:—Divide £376, 11s. 1 $\frac{1}{2}$ d. by 63: 63 is a composite number; its component parts are 7 and 9 (seven nines are 63). The given amount, therefore, is first divided by 7, and the quotient, £53, 15s. 10 $\frac{1}{2}$ d. is divided by 9. The result is the same as if the original sum had been divided by 63. £5, 19s. 6 $\frac{1}{2}$ d. is the quotient.

When the divisor is a prime number above 12, the work is in every respect similar to the former; but it is performed by long division, as in the annexed example:—Divide £484, 19s. 7 $\frac{1}{2}$ d. by 73. The amount being written down as in long division of simple numbers, the pounds are first divided by 73; the answer is 6. The remainder 46 is reduced to shillings by multiplying by 20, and the 19s. in the sum we are dividing being taken in, makes together 939s., which, divided by 73, gives 12, and 63 of a remainder. These 63 shillings are now reduced to pence by being multiplied by 12, and the 7 being taken in, makes 763; this, divided by 73, gives 10, and 33 over, which, being reduced to farthings by being multiplied by 4, and the three taken in, makes 135; and this, divided by 73, gives 1, and 62 over. The whole answer is £6, 12s. 10 $\frac{1}{2}$ d. and a fraction  $\frac{1}{3}$  over.

### British Weights and Measures.

The working of accounts in weights and measures, as respects addition, multiplication, subtraction, or division, proceeds on principles similar to those which have now been explained. The only real difference is that, for example, in reduction, instead of multiplying by 20, by 12, and by 4, to reduce a sum to farthings, if the question refer to ordinary weights we multiply to bring out the number of hundredweights, 112 for pounds, and 16 for ounces. Suppose we wish to know how many ounces are in 15 tons: we multiply 15 by 20, and the result is 300—that is, 300 hundredweights; a hundredweight is 112 pounds, so we now multiply 300 by 112, and the result is 33,600 pounds; this multiplied by 16, the number of ounces in a pound, gives 537,600 ounces. In the addition of quantities, each denomination is set down in its own column, as in money, and the summation is made also as we add money, with the difference, that we carry forward ounces, pounds, or whatever it may be, to the next column. The mark *cwt.* is usually employed to indicate hundredweights, *lb.* pounds, and *oz.* ounces.

The following are the principal tables of weights and

CHAMBERS'S INFORMATION FOR THE PEOPLE.

measures established by law in the United Kingdom, and hence called *imperial*. That which is entitled *avoirdupois weight* is the table in use for all ordinary purposes:—

I.—MEASURE OF LENGTH.

Inches.		1 Foot.		1 Yard.		1 Pole or Perch.		1 Furlong.		1 Mile.	
12	...	3	...	36	...	5½	...	40	...	8	...
36	...	3	...	36	...	5½	...	40	...	8	...
192	...	16½	...	54	...	1	...	1	...	1	...
7,920	...	650	...	520	...	40	...	1	...	1	...
63,560	...	5280	...	1760	...	320	...	8	...	1	...

The hand = 4 inches; the English ell = 45 inches; the pace = 5 feet; and the fathom = 6 feet. The geographical degree = 90 nautical leagues, or 69·121 miles. In land measure, the chain of 100 links = 66 feet; a link is equal to 7·92 inches.

II.—MEASURE OF SURFACE.

Sq. Inches.		1 Sq. Foot.		1 Sq. Yard.		1 Sq. Pole.		1 Rood.		1 Acre.	
144	...	9	...	27	...	30¼	...	40	...	4	...

1,668,160	...	10,890	...	1210	...	40	...	1	...	1	...
6,372,640	...	48,560	...	4240	...	160	...	4	...	1	...

And 640 acres make 1 square mile.

III.—MEASURES OF CAPACITY.

1. *Solidity.*

1728 cubic inches	=	1 cubic foot.
27 cubic feet	=	1 cubic yard.

The ton measurement = 8 barrel bulk, or 40 cubic feet.

2. *Measure for Liquids, Corn, and Dry Goods.*

Cubic Inches.	Wat. lbs. av.	1 GILL.		1 Pint.		1 Quart.		1 Gal.		1 Peck.	
8-665	5	4	...	8	...	2	...	2	...	8	...
34-669	1½	8	...	16	...	4	...	4	...	32	...
69-318	2½	16	...	32	...	8	...	8	...	64	...
277-274	10	32	...	64	...	16	...	16	...	128	...
554-548	20	64	...	128	...	32	...	32	...	256	...
2218-19	80	256	...	512	...	128	...	128	...	1024	...
17745-5	640	3048	...	512	...	256	...	64	...	32	...

4 pecks = 1 bushel; 8 bushels = 1 quarter.

The peck, bushel, and quarter, are used for dry goods only. There are, besides, the coom = 4 bushels; the wey or load = 5 quarters; and the last = 2 loads or 10 quarters.

According to the system introduced January 1, 1826, the imperial gallon contains 277,274 cubic inches, or 10 lbs. avoirdupois of distilled water at 62° Fahrenheit, the barometer being at 30 inches. Heaped measures (formerly used for dry goods) were abolished in 1835.

Troy Grains.	IV.—MEASURES OF WEIGHT.	
57-34375	1 Drachm.	
437-5	16	...
7000	256	...
89000	3,584	...
126000	7,168	...
784000	28,672	...
1568000	573,440	...

Flour Weight.—1 peck = 14 pounds; 1 boll = 140 pounds; 1 sack = 280 pounds, or 2½ cwt.; 1 barrel = 196 lbs.

2. *Troy Weight.*

Grains.	1 Pennyweight.		1 Ounce.		1 Pound.	
24	...	150	...	4,800	...	57,600
480	...	30	...	960	...	11,520
8790	...	240	...	12	...	1

This weight is used in weighing gold, silver, platinum, &c. The fineness of gold is expressed in carats and grains, the pound or other weight being divided into 24 carats, and the carat into 4 grains. Thus the carat pound is the 24th part of the troy pound, or 10 dwts., and the carat grain the 96th part of the troy pound, or 60 troy grains.

In *Beer Measure*, the barrel contains 4 firkins or 36 gallons; and the hogshead 1½ barrel or 54 gallons.

In *Wine Measure*, besides the gallon and its subdivisions, various denominations are used, as the butt,

pipe, &c.; but these are now to be considered rather as the names of casks than as expressing any definite number of gallons. The *standard gauges* in trade are as follows:—Pipe of port, 115 imp. galls.; pipe of Lisbon, 117 do.; pipe of Cape or Madeira, 92 do.; pipe of Teneriffe, 100 do.; butt of sherry, 108 do.; hogshead of claret, 46 do.; sum of hock, 30 do.

*Herrings* are measured by the barrel of 26½, or cran of 37½ gallons.

*Apothecaries' Weight*.—20 troy grains make 1 scruple, 3 scruples make 1 drachm, and 8 drachms make 1 ounce. The ounce and pound are the same as in troy weight. This weight is used in medical prescriptions only. The fluid measures used by apothecaries are—60 minims make 1 fluid drachm, 8 drachms 1 fluid ounce, 20 fluid ounces 1 pint, 8 pints 1 gallon. (See No. 48.)

The Scottish acre, formerly a standard in Scotland, and now abolished, consisted of 54987·15 imperial square feet: 25 Scots acres were very nearly equal to 29 imperial acres. The Scottish *choppin* was very nearly the English wine quart, and the *mutchkin* was rather more than the English pint. Previous to the Union with England, the Scottish money pound was equal to one shilling and eightpence English. Hence £100 Scots was equal to the sum of £8, 6s. 8d. in our present money.

V.—MEASURES OF TIME.

A second	.	sec.	sec.	min.				
60 sec.	=	1 minute	60	=	1 hr.			
60 min.	=	1 hour	2600	=	60 =	1 day.		
24 hr.	=	1 day	86400	=	1440 =	24 =	1 wk.	
7 days	=	1 week	604800	=	106680 =	168 =	7 =	1

365 days, or 52 weeks 1 day = 1 common year.

366 days, or 52 weeks 2 days = 1 leap year.

365 days 6 hours = 1 Julian year.

366 days 5 hours 48 minutes 49 seconds = 1 solar year.

French Weights and Measures.

As French weights and measures are now frequently referred to in literature, we think it proper to offer the following particulars on the subject:—

The French system of weights and measures is established on a principle much more simple and unerring than that in use in England—the former is of universal application, the latter can never be anything but local. The French unity of length and weight is based on an invariable dimension of the terrestrial globe, which is recognisable in all countries. It is independent of all extrinsic notions, such as gravity and the arbitrary subdivisions of duration, an advantage which the length of a seconds pendulum certainly does not present. The admeasurement of a fourth of the earth's meridian—an ideal circle going round the globe from pole to pole at right angles with the equator—constitutes the basis of the French system. The length of this fourth of the meridian is divided into 10,000,000 parts; a single ten-millionth part is the *metre*, or the unity of long measure. (A metre is equal to 39½ British inches.)

A square, measuring on each side 10 metres, forms the *are*, or the unity of the mensuration of surface. (40½ ares are nearly equal to one British acre.)

A cube, measuring on each of its sides 1 metre, constitutes the *stere*: used for dry measure.

A cube, measuring on each of its sides the tenth part of a metre, is the unity of volume. A vessel gauging such a cube, is the unity of liquid measures, and is called the *litre*. (A litre is equal to about a pint and three-quarters, or nearly a quart British measure.)

The weight of a cube of water, measuring on each of its sides the 100th part of a metre, is the unity of weight, and is called the *gramme*. A thousand grammes of pure water at its greatest density (about 40 degrees of Fahrenheit's thermometer), are of course equivalent to the litre. (A thousand grammes, forming 1 kilogramme, weigh about 2½ pounds British.)

These unities being often too great or too small for common use, they constitute the basis of new unities on the simple decimal principle. The names of these new unities are formed from Greek and Latin words. If to express multiplication of the original unity, Greek is

used; if to express division of the original unity, Latin is used, or words slightly modified from it. The Greek words are, *deka*, for ten, *hecto*, a hundred, *kilo*, a thousand, and *myria*, ten thousand. The Latin words are, *decem*, for ten, *centum*, a hundred, and *mille*, a thousand. These various words are placed before, or prefixed to, the principal unity. Thus the *decimetre* is equal to ten metres, and the *decimetre* is the tenth part of a metre; the *hectolitre* is equal to 100 litres, and the *centilitre* is the hundredth part of a litre; the *kilogramme* is equal to a thousand grammes, and the *milligramme* is the thousandth part of a gramme.

The connection between these weights and measures will now be clearly seen. The *are* is the square decimetre; the *litre* is the cubic decimetre; and the *kilogramme* is the weight of a litre of pure water at its maximum density.

The currency of the country being assimilated by decimal reckoning to the weights and measures, it may be safely averred that the whole world cannot produce a more simple and immutable plan of calculation than that now in use in France and in Belgium.

FRACTIONS.

Hitherto we have spoken only of whole numbers, which in arithmetic are called *integers*. We have now to treat of fractions, or the parts into which integers may be broken. The more ordinary fractions of any single article or number are a half, third, quarter, &c.; but a number admits of being divided into any quantity of equal parts. All such fractions are called *vulgar fractions*, from their being common. It is the practice to write vulgar fractions with two or more small figures, one above the other, with a line between, as follows:— $\frac{1}{2}$  (one-half),  $\frac{1}{3}$  (one-third),  $\frac{1}{4}$  (one-fourth or quarter),  $\frac{1}{8}$  (one-eighth),  $\frac{4}{5}$  (four-fifths),  $\frac{9}{10}$  (nine-tenths), and so on. In these and all other instances, the upper number is called the *numerator*, the lower the *denominator*. Thus in the fraction  $\frac{9}{10}$ , 9 is the numerator, and 10 the denominator—the latter denominating or showing into how many parts the original unit is supposed to be divided, and the former pointing out how many such parts are in the fraction spoken of.

It may happen that it is necessary to add together different fractions to make up whole numbers. In working all such questions, we must, in the first place, bring all the fractions into one kind: if we have to add  $\frac{1}{2}$ ,  $\frac{1}{3}$ , and  $\frac{1}{4}$  together, we make all into eighths, and see how many eighths we have got; thus  $\frac{1}{2}$  is  $\frac{4}{8}$ ; then  $\frac{1}{3}$  is  $\frac{2}{6}$ , that is 2 and 4, which make 6, and  $\frac{1}{4}$  makes a total of  $\frac{14}{8}$ . The same plan is to be pursued in the subtraction of vulgar fractions.

It is sometimes necessary to speak of the tenths, hundredths, or thousandths of a number, and for this arithmetic has provided a system of *decimal fractions*. Where great exactness of expression is required, decimals are indispensable. It has been already shown that in writing common numbers, the value of a figure increases by ten times as we proceed from right to left; in other words, we ascend by tens. Now there is nothing to prevent us in the same manner descending by tens from unity. This is done by decimal fractions. We place a dot after unity, or the unit figure, which dot cuts off the whole number from its fractional tenths; thus, 120·3 means 120 and 3-tenths of a whole; if we write 120·31, the meaning is 120 and 31-hundredths of a whole—that is, 31 parts in 100 into which a whole is supposed to be divided. If we go on adding a figure to the right, we make the fraction into thousandths; as, for instance, 120·315, which signifies 120 and 315 out of a thousand parts.

Tables of specific gravities, population, mortality, and many matters of statistics, are greatly made up of decimal fractions, and therefore it is proper that all should comprehend the principle on which they are designed. In many cases, it would answer the purpose to write the fractions as vulgar fractions; but there is a great advantage in reducing all broken parts to the

decimal notation, for it allows of adding up columns of decimals all of the same denomination. Their great excellence, indeed, consists in the uniformity which they give to calculation, and the easy methods which, by these means, they present of pursuing fractional numbers to any degree of minuteness.

The method of reducing a vulgar to a decimal fraction is a simple question in Division. For instance, to reduce  $\frac{3}{4}$  to a decimal, we take the 3, and putting two ciphers after it, divide by 4, thus  $\frac{300}{4}$ ; therefore  $\cdot 75$  is the decimal; or, what is the same thing, 75-hundredth parts of a whole are equal to three-quarters.

SERIES AND RATIOS OF NUMBERS.

A series of numbers is a succession of numbers that increase or decrease according to some law. Of the two kinds of series usually treated of in arithmetic, the simpler is one whose terms increase or decrease by some constant number called the *common difference*. This common difference or rate of increase is only one, when we say 4, 5, 6, 7, 8; it is two when we say 7, 9, 11, 13; and four when we say 6, 10, 14, 18, and so on. Every advancement of this nature, by which the same number is added at every step, is called *arithmetical progression*. There is a different species of advancement, by which the last number is always multiplied by a given number, thus causing the series to mount rapidly up. Suppose 4 is the multiplier, and we begin at 2, the progression will be as follows:—2, 8, 32, 128, 512, 2048, and so on. It is here observed, that multiplying the 2 by 4, we have 8; multiplying the 8 by 4, we have 32; and multiplying the 32 by 4, we have 128, &c. till at the fifth remove we attain 2048. This kind of advancement of numbers is called *geometrical progression*. The very great difference between the two kinds of progression is exemplified in the following two lines, the number 3 being added in the one case, and being used as the multiplier in the other:—

- 5, 8, 11, 14, 17—Arithmetical Progression.
- 5, 15, 45, 135, 405—Geometrical Progression.

In the case of arithmetical progression, as above or in any other manner exemplified, it may be noticed that the amount of the first and last term is always the same as twice the amount of the middle term; thus 5 and 17 being 22, are equal to twice 11, or 22. The cause of this is, that as the numbers increase or decrease in equal degrees, the last number is just as much more as the first is less than the number in the middle; and the two being added, the amount must consequently be double the central number. The same rule holds good with respect to any two numbers at equal distances from the number in the middle. If the series be an even number, and do not possess a middle term, then the two terms nearest the middle (called the mean terms) must be added together; thus in the natural series from 1 to 24, 12 and 13 are the two nearest the middle, and one being added to the other makes 25, the sum of the first and last term.

In geometrical progression, each term is a factor of all the numbers or terms that follow, and a product of all that go before, so that there is a harmonious ratio pervading the whole. Each term bears an exact proportion to its predecessor, because the multiplier is the same. Supposing, as above, the multiplier to be 3, the term 15 is proportionally greater than 5, as 45 is greater than 15. In the technical language of arithmetic, as 15 is to 5, so is 45 to 15. To save words, such a proposition is written with signs or abbreviations thus—15 : 5 :: 45 : 15. The two dots mean *is to*, and four dots mean *so is*. The same formula is applicable to any series of proportional terms, though not in continued proportion to each other.

In order to discover the ratio between any two terms, we divide the largest by the least, and the quotient is the ratio: 45 divided by 15 gives 3 as the ratio. By thus ascertaining the ratio of two terms, we are fur-

CHAMBERS'S INFORMATION FOR THE PEOPLE.

nished with the means of arriving at the ratio of other terms. We cannot do better than explain the method of working out this principle in the ratio of numbers, by giving the following passages from the admirable 'Lessons on Arithmetic,' by Mr T. Smith of Liverpool. Taking the four regularly-advancing terms, 15, 45, 405, and 1215, he proceeds—'Suppose that we had only the first three, and that it were our wish to find the fourth, which term bears the same proportion to the third as the second does to the first. The thing we have first to do is, to discover the ratio between the first and second terms, in order to do which, as before shown, we divide the larger by the smaller, and this gives us the ratio 3, with which, by multiplying the third term, we produce the fourth; or let the three terms be these, 405, 1215, 5, and let it be our wish to find a fourth which shall bear the same relation to the 15 as 1215 does to 405. We divide and multiply as before, and the fourth term is produced. And in this manner, having two numbers or two quantities of any kind, bearing a certain proportion towards each other, and a third, to which we would find a number or quantity that should bear a like proportion, in this manner do we proceed, and thus easily may we find the number we require.'

Referring to the discovered ratio of 45 to 15 to be 3, or the fifteenth part—'Now,' continues this author, 'what would have been the consequence had we multiplied the third term (405) by the whole, instead of by a fifteenth part of the second? The consequence would have been, that we should have had a term or number fifteen times larger than that required. But this would be a matter of no difficulty; for it would be set right at once, and our purpose gained, by dividing the over-large product by 15. Let us write this process down: 405 x 45 = 18225, and 18225 ÷ 15 = 1215,—which 1215 bears the same proportion to 405 as does 45 to 15. And this is the rule, when the terms are properly placed—*Multiplying the second and third terms together, and dividing the product by the first*; this avoids all the difficulties arising from the occurrence of fractions in the course of the process, and gives us in all cases any proportional terms we may require.'

Rule of Three.

On the principle now explained, we can, in any affairs of business, ascertain the amount of an unknown quantity, by knowing the amount of other three quantities, which, with the unknown quantity, bear a proportional relation. The word *quantity* is here used, but any *sum of money* is also meant.

Let it be remembered that the *ratio* of one number to another is the number of times that the former contains the latter; for example, the ratio of 6 to 3 is 2, that of 12 to 4 is 3, and that of 8 to 12 is  $\frac{2}{3}$ . When two numbers have the same ratio as other two, they constitute a *proportion*. Thus the ratio of 8 to 6 is the same as that of 12 to 9, and the equality of these two ratios is represented thus:—

$$8 : 6 = 12 : 9, \text{ or } 8 : 6 :: 12 : 9.$$

The following is the rule for stating and working questions:—Make that term which is of the same kind as the answer sought, the *second* or *middle* term. Consider, from the nature of the question, whether the answer should be more or less than this term; if *more*, make the *smaller* of the other two terms the *first*, and the *greater* the *third*; if the answer should be *less* than the middle term, make the *greater* of the two terms the *first*, and the *smaller* the *third*; then multiply the second and third terms together, and divide the result by the first term. The quotient found will be the answer to the question, and it will be found to bear the same proportion to the third term as the second does to the first. Suppose the question be this:

If 3 lbs. of tea cost 9s., how many pounds may be purchased for 21s.?  
—state the terms, with the larger sum last. Should the question, however, be the reverse—If 7 lbs.

$$21 : 7 :: 3$$

$$\frac{7}{21} \overline{) 21}$$

$$1 \text{ lb.}$$

$$4 : 8 :: 10$$

$$\frac{8}{4} \overline{) 80}$$

$$20 \text{ days.}$$

of tea cost 21s., how much may be purchased for 3s. 1.—then the sum to be ascertained is less, and is put last. Suppose another plain example: If 10 men can execute a piece of work in 8 days, how long will 4 men take to do the same!

Such is the principle of working Rule of Three questions, whatever be their apparent complexity. If either the first or third term, or both, include fractional parts, they must be reduced to the denomination of the fractions before working: thus if one be reduced to shillings, the other must be made shillings also; if to pence, both must be pence; and so on. If the middle term be also a compound quantity, it may either be reduced to its lowest term, before multiplying and dividing by the other terms, or you may multiply and divide by Compound Division and Multiplication.

If the middle term be reduced to its lowest term, the answer will be in that denomination to which it was reduced; thus if it were brought to farthings, the answer would be in farthings; if to ounces, the answer would be in ounces.

Example.—If 2 cwts. 1 qr. 7 lbs. sugar cost £8, 14s. 4d., what will 14 cwts. 3 qrs. cost!

cwt.	qr.	lb.	£	s.	d.	cwt.	qr.	lb.		
2	1	7	:	8	14	4	::	14	3	0
				20				4		
				9				174		59
				28				12		28
				259				2092		472
										118

Here, in order to make the first term a simple number, it is reduced to its lowest term—namely, lbs. The third term is therefore reduced to lbs. also, that both may be alike. The second or middle term is reduced to its lowest term, pence. After multiplying and dividing, according to rule, the quotient is 13343 pence, which are brought to shillings and pounds. The remainder, 147, being farther reduced to farthings, and divided by the first term, gives 2 farthings. The answer is £55, 11s. 11½d. 7ff.

										1652

						1036				
						924				
						777				
						147				
						4				
259						588	(2)			
						518				
						70				

The following is a kind of question which often occurs in business:—A person is unable to pay his debts. He owes to A £540, to B £260, to C £200, being in all £1000. On examining his affairs, it is found that he possesses property only to the value of £370. How, then, is this to be divided proportionally among the three creditors, so that each may receive a fair share? The way to arrive at an answer, is to work out each creditor's share as a distinct account. Thus, first, as to A's share:—

The answer is £199, 16s. Following a similar calcu-

tial payment is made, and add it to the principal; from this sum subtract the money paid, and the remainder is a new principal; compute the interest on this principal from the time of the first payment up to the time of the second payment, add it to the latter principal; from the sum subtract the second sum paid, and the remainder is again a new principal; and continue this process till the last payment.

Mensuration.

Mensuration refers to the measurement of objects, and is of three kinds—*lineal*, or measuring by mere length; *superficial*, which respects breadth as well as length; and *solid*, which includes length, breadth, and thickness. In the United Kingdom, the foot of twelve inches is the common standard of measurement. A draper measures cloth with a rod of three feet or one yard, and workmen usually measure the dimensions of walls, or the superficies of apartments, by a ribbon marked in feet and inches. In common usage, the inch is divided into eighths and sixteenths.

As lineal measurement requires no explanation, we pass to a consideration of superficial measurement, or that of both length and breadth. A *superficial foot*, which is the basis of this kind of measurement, is either a square of a foot in length and a foot in breadth—in other words, a foot each way—or it is any dimension in which the length multiplied by the breadth will form a foot. For example, the surface of a piece of wood, 2 feet in length and 6 inches in breadth, is a superficial foot. A superficial foot is generally called a square foot, and is a superficies consisting of 12 times 12, or 144 square inches. Sometimes the term *square feet* is confounded with that of *feet square*, which is quite a different thing. A piece of cloth said to measure six square feet, consists of six squares of a foot each; but a piece said to measure *six feet square* would be six feet along each side, and comprise thirty-six squares of a foot each. Inattention to these distinctions has often led to awkward errors and disputes.

The method of finding the superficial contents of any oblong surface, is to multiply the length by the breadth; but other points require attention in the calculation. To arrive at exactness, the inch is reckoned to contain 12 seconds or parts, each second contains 12 thirds, and each third contains 12 fourths. Feet multiplied by feet, give feet; feet multiplied by inches, give inches; feet multiplied by seconds, give seconds; inches multiplied by inches, give seconds; inches multiplied by seconds, give thirds; and seconds multiplied by seconds, give fourths.

**Rule for working questions**—1. Write the multiplier under the multiplicand, feet under feet, inches under inches, seconds under seconds, &c. 2. Multiply each denomination of the length by the feet of the breadth, beginning at the lowest, and place each product under that denomination of the multiplicand from which it arises, always carrying 1 for every 12. 3. Multiply by the inches, and set each product one place farther to the right hand. 4. Multiply by the seconds or parts, and set each product another place towards the right hand. 5. Proceed in this manner with all the rest of the denominations, and their sum will be the answer.

**Example**.—Multiply 6 feet 3 inches by 3 feet 2 inches. In working, we begin by multiplying the 3 inches by 3, and then the 6 feet also by the same 3 below it; this gives 18 feet 9 inches. This makes 18, 9. We now multiply by the 2 inches, placing the 6 one remove to a side. By then multiplying the 6 by 2, we have 12 inches or 1 foot, and setting down the one below the 18, we add up. The answer is 19 feet 9 inches and 6 seconds. Questions of this kind may also be wrought by decimals.

To measure the *solid* contents of an object, a different process is pursued. Suppose we take a piece of wood measuring a square foot, and cover it with dice, each die an inch square and an inch high, the wood will be covered with exactly 144 dice. Let us now put

a second layer of dice on the first, and the number will be doubled, or 288 dice; and if we thus go on adding layer above layer till we have 12 layers, the number of dice will be finally 12 times 144, or 1728 dice; in other words, we shall have formed a cube consisting of 1728 solid inches. Such is solid measure.

Solid measure is computed arithmetically, by multiplying the length by the breadth, and the product by the thickness. Civil engineers, who require to calculate the solid contents of masses of earth, with a view to excavation, resort to this simple rule; it is likewise

followed by builders in reference to walls, plumbers to cisterns, and other artificers. The following is a question not unlikely to occur. Required the contents of a cistern 9 yards 2 feet in length, 6 yards 2 feet in breadth, and 4 yards 2 feet in depth. Analyse these dimensions—9 yards 2 feet are 29 feet; 6 yards 2 feet are 20 feet. Multiply the 29 by 20, and then multiply by 14 (14 feet being equal to 4 yards 2 feet); next divide by 27, which is the number of solid feet in a solid yard. The question is thus wrought in the margin. The answer is seen to be 300 yards 20 feet.

$$\begin{array}{r} 29 \\ 20 \\ \hline 580 \\ 14 \\ \hline 2320 \\ 580 \\ \hline 27)8120 \\ \underline{5400} \\ 300 \text{ y. } 20 \text{ f.} \end{array}$$

Evolution.

The extraction or discovery of the square and cube roots of numbers, forms a department of arithmetic called *Evolution*, and is useful in some kinds of measurement. In the following table, the squares, cubes, and fourth and fifth powers of the nine units are given. The square of any number, it will be observed, is gained by multiplying the number by itself; the cube, by multiplying the square by the number; the biquadratic by multiplying the cube by the number; and the sursolid by multiplying the biquadratic by the number:—

Root, or 1st power, .	1	2	3	4	5	6	7	8	9
Square, or 2d power, .	1	4	9	16	25	36	49	64	81
Cube, or 3d power, .	1	8	27	64	125	216	343	512	729
Biquad., or 4th power, .	1	16	81	256	625	1296	2401	4096	6561
Sursolid, or 5th power, .	1	32	243	1024	3125	7776	16807	32768	59049

The powers of numbers are usually expressed by adding a small figure to them; thus 3<sup>2</sup> signifies the second power or square of 3—that is, 3 × 3 = 9; 3<sup>3</sup> signifies the third power or cube of 3, or 3 × 3 × 3 = 27. The small figure thus added is called an *index* or *exponent*, because it indicates or exposes to view the powers of the quantity to which it is affixed. The square root of any small quantity may easily be ascertained by means of the multiplication table; for instance, 6 is at once seen to be the square root of 36, because 6 × 6 = 36; but when larger numbers occur, it is requisite to have recourse to another process.

Supposing it were required to find the length of the side of a square which contains 59,049 square inches on its surface, it is evident that it cannot at once occur to the mind what number, by being multiplied into itself, produces this quantity. It is therefore requisite to find the square of one part of the number, and then the square of the other part. To effect this, the whole number is divided into parts, by a dot being placed over each alternate figure, beginning at the unit. The reason for thus separating it into periods of two figures each, is because the square of a single figure never consists of more than two places, the square of a number of two figures of not more than four places, &c.

After the whole number has been thus divided, the root whose square comes nearest to the first period must be placed in the quotient, and its square subtracted from the first period. Thus 5 being the first period, 2, as being the root of 4, is placed in the quotient, and the square of 2 (2 × 2 = 4) is subtracted from 5, because 5 here forms the first period. The next period (90) is then annexed to the remainder for a new dividend. The root is doubled for a divisor, and

$$\begin{array}{r} 59049(243 \\ 4 \\ \hline 44)190 \\ \underline{176} \\ 483)1449 \\ \underline{1449} \end{array}$$

## ARITHMETIC.

after ascertaining how often it is contained in the dividend, omitting its last figure, the result (4) is placed both in the quotient and also in the unit's place of the divisor: the whole number (44) thus formed, must be multiplied by 4, and the product must be subtracted from the dividend. The same process must be repeated until there is no remainder, and the quotient will contain the root sought, which in this case is 243. The rule for extracting the cube root is equally tedious, and indeed almost too complex for practical purposes. The methods of extracting the roots of higher powers are so complicated, that they are usually omitted in arithmetical works. The 4th, or biquadratic root, may be ascertained by extracting the square root twice, because it is the square root of the square root. The 6th root is the square root of the cube root, or the cube root of the square root.

The 8th root, being the square root of the biquadratic root, may be found by extracting the square root three times. In the same way, the 9th root may be called the cube root of the cube root, and may be found by extracting the cube root twice. But the common arithmetical operations furnish no method of obtaining the 5th, 7th, 10th, 13th, 14th, 15th, 17th, 19th, 20th, and most other roots; and this part of arithmetic continued, therefore, involved in practical difficulties, until the invention of logarithms.

### LOGARITHMS.

Logarithms (from two Greek words, signifying the number of the ratios or proportions) is a branch of arithmetic of comparatively modern invention, the discoverer having been John Napier of Merchiston, near Edinburgh, in the early part of the seventeenth century. The principles upon which logarithms are founded, may perhaps be rendered familiar by the following illustration:—Supposing that 1 is the first term of a geometrical progression, and that the ratio or multiplier is 2, the terms stand in the following manner:—

1	is the first term.
2	... ratio.
4	... square of the ratio.
8	... cube of the ratio.
16	... 4th power of the ratio.
32	... 5th power of the ratio.
64	... 6th power of the ratio.

All this might, however, have been conveyed far more concisely by substituting signs for words, thus:—

It is evident that this might have been expressed still more concisely by omitting the number signifying the ratio (2) throughout, retaining only the indices or exponents, they alone being sufficient to indicate the degree of power to which the ratio is raised in each term. Exponents thus placed in order, opposite to a series of numbers in geometrical progression, are, as we have said, called Logarithms, or literally, *number of the ratio*.

The most tedious sums in multiplication can, by means of logarithms, be solved simply by addition. For instance, if it were required to multiply 256 by 32, it would merely be requisite to add the logarithms standing opposite to those two numbers—their sum (13) stands opposite the product required, namely, 8192:—

Num.	Log.	Num.	Log.
1	...	128	...
2	...	256	...
4	...	512	...
8	...	1024	...
16	...	2048	...
32	...	4096	...
64	...	8192	...

Again, to multiply 128 by 16, we take the 7th + 4th, or 11th, power of 2, because 128 is the 7th and 16 the 4th power of 2; opposite to the sum of 7 and 4 (11) is 2048, equal to the result of the multiplication of the two numbers. This also affords a quick and easy method of dividing one number by another: thus if it be required to divide 4096 by 16, it is only requisite to ascertain the difference between the logarithm of these two numbers, which in this case being 8, the figure opposite to

8 is the required quotient, indicating how often 16 is contained in 4096—namely, 256 times.

The indices or exponents, 1, 2, 3, 4, &c. might, however, denote the powers of any other number or ratio. Every different ratio or geometrical progression gives a different system of logarithms. Soon after the invention of logarithms by Lord Napier, it occurred to Briggs, then professor of geometry at Oxford, that a system whose base or ratio is 10 is preferable to all others, on account of its being analogous to the general method of notation. In A. D. 1624, Briggs published the tables of logarithms which are now in common use. In this system, 10 being the ratio or multiplier, the terms may be thus expressed—

1	10	100	1000	10,000, &c.
10 <sup>0</sup>	10 <sup>1</sup>	10 <sup>2</sup>	10 <sup>3</sup>	10 <sup>4</sup> &c.

The exponents, 1, 2, 3, 4, are, as was shown in the previous table, the logarithms of the opposite numbers, and might therefore have been written thus—

1	10	100	1000	10,000, &c.
0	1	2	3	4 &c.

The logarithms of all intermediate numbers, such as those between 1 and 10, 10 and 100, &c. are found by ascertaining the geometrical mean proportions between any two numbers, and likewise the corresponding arithmetical means between the indices of those numbers. In every system, 0 is the logarithm of 1. Hence the logarithm of any number between 1 and 10 must be less than a whole number, and therefore a decimal fraction; and the logarithm of any number between 10 and 100 must be one with a fraction. In the same way, the logarithm of any number between 100 and 1000 must be 2 and a fraction, and so on, through the rest of the series. The integers, 0, 1, 2, 3, &c. to the left of the decimals in logarithms, are called the *characteristics* of those logarithms. Thus 0 is the characteristic of all numbers between 1 and 10; 1 is the characteristic of all between 10 and 100; 2 that of all between 100 and 1000, &c. In tables of logarithms the characteristics are generally omitted. [For a complete and accurate collection of MATHEMATICAL TABLES, the reader is referred to CHAMBERS'S EDUCATIONAL COURSE.]

The method of using a table of logarithms is the following:—To ascertain, in the most common tables, the logarithm of a number less than 10,000, it is merely necessary to find the first three figures of the number in the left-hand column, and the fourth figure in the horizontal line at the top; then opposite to the former, and under the latter, is the required logarithm. If the given number consist of five figures, find, as before, the logarithm belonging to the first four figures; the difference between it and the next logarithm may be ascertained from the margin; this difference is to be multiplied by the fifth figure of the given number, and one figure cut off from the right of the product; and the other figures of this product being added to the preceding logarithm, and the index 3 prefixed, the sum will be the required logarithm.

The process of finding the natural number of any given logarithm is precisely the converse of that just described. The given logarithm must be sought in the table; and against it, in the left-hand column, will be found the natural number. It has already been shown that tables of logarithms afford an easy method of finding the product in multiplication, and the quotients in division, by means of simple addition and subtraction. Logarithms are equally applicable to the solution of questions in Proportion or the Rule of Three, it being merely requisite to add the logarithms of the second and third terms together, and from the sum to subtract the logarithm of the first: the remainder is the logarithm of the fourth term.

A number may, by means of logarithms, be raised to any required power, by multiplying the logarithm of the number by the index of the power. Thus to square any number, multiply its logarithm by 2; to cube a number, multiply its logarithm by 3; and so on.

To extract the root of any given number, the logarithm of the number must be divided by the proposed

index, and the quotient is the logarithm of the required root. Thus to find the square root of 169, it is only necessary to divide its logarithm, which is 2.2278867 by 2; opposite to the quotient will be found the number 13, which is the square root of 169, because  $13 \times 13 = 169$ . [To those who desire a thorough knowledge of ARITHMETIC, we refer to the complete and accessible treatise, by Mr Marr, published in CHAMBERS'S EDUCATIONAL COURSE.]

ALGEBRA.

We have seen that logarithmic tables may be used as a substitute for many lengthened operations in arithmetic. It is evident that the value of all methods of computation lies in their brevity. Algebra must be considered as one of the most important departments of mathematical science, on account of the extreme rapidity and certainty with which it enables us to determine the most involved and intricate questions. The term *algebra* is of Arabic origin, and has a reference to the resolution and composition of quantities. In the manner in which it is applied, it embodies a method of performing calculations by means of various signs and abbreviations, which are used instead of words and phrases, so that it may be called the system of symbols. Although it is a science of calculation, yet its operations must not be confounded with those of arithmetic. All calculations in arithmetic refer to some particular individual question, whereas those of algebra refer to a whole class of questions. One great advantage in algebra is, that all the steps of any particular course of reasoning are, by means of symbols, placed at once before the eye; so that the mind, being unimpeded in its operations, proceeds uninterruptedly from one step of reasoning to another, until the solution of the question is attained.

Symbols are used to represent not only the known, but also the unknown quantities. The present custom is to represent all known quantities by the first letters of the alphabet, as *a, b, c*, &c. and the unknown quantities by the last letters, *x, y, z*.

The symbols used in arithmetic to denote addition, subtraction, &c. belong properly to algebra. Thus the sign  $+$  plus, denotes that one quantity is to be added to another, and is called the positive or additive sign; all numbers to which it is prefixed are called *positive*. The sign  $-$  minus, denotes that one quantity is to be subtracted from another; it is called the negative or subtractive sign, and all quantities to which it is prefixed are called *negative*. If neither  $+$  nor  $-$  be prefixed to a quantity, then the sign  $+$  plus is understood.

The general sign to denote that one number is to be multiplied by another, is  $\times$ ; but it often occurs that one letter has to be multiplied by another, and this is represented by placing those letters one after the other, generally according to the order in which they stand in the alphabet; thus *a* multiplied by *b*, is expressed by *ab*. The multiplication of quantities consisting of more than one term, as for instance  $a + b$  by  $c + d$ , may be represented by any one of the following methods:  $\overline{a + b} \times c + d$ , or  $a + b \cdot c + d$ , or  $(a + b)(c + d)$ . The bar drawn over  $a + b$  and  $c + d$ , which in the two first examples marks them as distinct quantities, is called a *vinculum*, but brackets or parentheses, as in the last example, are now in more frequent use.

When a letter is multiplied by any given number, it is usual to prefix that number to the letter. Thus twice *a*, three times *b*, four times *c*, six times *x*, &c. are expressed thus:  $2a, 3b, 4c, 6x$ ; and the numbers 2, 3, 4, 6, thus prefixed, are called the *coefficients* of the letters before which they stand.

The sign  $\div$  between two numbers shows, as in arithmetic, that the former of those numbers is to be divided by the latter; thus  $a \div b$ , means that *a* is to be divided by *b*. It is, however, more usual to place the number to be divided above that by which it is to

be divided, with a small line between, in the form of a fraction; thus  $\frac{a}{b}$  denotes that *a* is divided by *b*.

It has been shown in Arithmetic that the powers of quantities are denoted by a small figure, called the exponent or index of the power. Thus  $a \times a$ , or the square of *a*, is expressed by  $a^2$ ;  $b \times b \times b$ , or the cube of *b*, is expressed by  $b^3$ , &c. The cube of  $a + b$ , or of  $(a + b)(a + b)$  is expressed thus:  $(a + b)^3$ .

The roots of quantities are represented by the sign  $\sqrt{\quad}$ , with the proper index affixed; thus  $\sqrt[4]{a}$ , or, more simply,  $\sqrt{a}$ , expresses the square root of *a*;  $\sqrt[3]{a}$  the cube root of *a*;  $\sqrt[4]{a + b}$  represents the 4th or biquadratic root of  $a + b$ . Fractional indices are also frequently used to denote the roots of quantities, thus:

$a^{\frac{1}{2}}$  is the square root of *a*.

$a^{\frac{1}{3}}$  is the cube root of *a*.

$a^{\frac{1}{4}}$  is the 4th root of *a*, &c.

Again,  $a^2$  is the cube root of  $a^3$ , or of the square of *a*.

$a^3$  is the square root of  $a^6$ , or of the cube of *a*.

$a^{\frac{1}{5}}$  is the 5th root of  $a^{\frac{1}{2}}$ .

When two or more letters or quantities are connected together by signs, the combination is called an algebraic expression, and each letter or quantity is called a *term*.

Quantities of one term are called simple quantities; as *a, 2a, 3b*, &c.

A quantity of two terms, as  $b + c$ , is called a *binomial*.

When a binomial expresses the difference between two quantities, it is called a *residual*, as  $a - b$ .

A quantity consisting of 3, 4, or many terms, are called respectively *trinomials, quadrimomials, multinomials*.

The sign  $=$  placed between two quantities shows, as in arithmetic, the *equality* of those quantities.

When quantities are connected by this sign, the expression is called an *equation*: thus,  $2 + 4 = 6$ , is an equation; as also,  $a + b = c - f$ .

The symbol  $>$  or  $<$  is called that of *inequality*, it being placed between two quantities, of which one is greater than another; the open part of the symbol is always turned towards the greater quantity: thus,  $a > b$  denotes *a* to be greater than *b*; and  $c < d$  denotes *d* to be greater than *c*. The sign of difference is  $\sim$ , only used when it is uncertain which of two quantities is the greater; thus,  $e \sim f$  denotes the difference between *e* and *f* when it is uncertain which is the greater.

The word *therefore*, or *consequently*, often occurring in algebraical reasoning, the symbol  $\therefore$  has been chosen to represent it: thus the sentence, 'Therefore  $a + b$  is equal to  $c + d$ ,' is thus expressed in algebra,  $\therefore a + b = c + d$ .

*Like* quantities are such as consist of the same letter or letters, or powers of letters: thus,  $6a$  and  $2a$  are like quantities, and also  $4abc$  and  $9abc$ . *Unlike* quantities are such as consist of different letters; as,  $4a, 5b, 6ax^2, 4ad$ , which are all unlike quantities.

Addition.

The operation of addition in arithmetic consists, as has been shown, simply in joining or adding several quantities together: thus,  $4 + 8 + 7 + 6 = 25$ . This same process is always used in algebra, whenever *like* quantities with *like* signs are required to be added: thus,  $2a + 3a + 6a = 11a$ ; and  $-7b - 4b - 6b = -17b$ . But as it often happens that like quantities which are to be added together have unlike signs, addition has in algebra a far more extended signification than in arithmetic. Thus to add  $7a + 4a$  to  $8a - 3a$ , it is evident that, after  $7a + 4a + 8a$  have been added according to the usual method,  $3a$  must be subtracted. Hence the general rule for the addition of *like* quantities with *unlike* signs is to add first the coefficients of the positive terms, and then to add those of the negative terms; the less sum must be subtracted from the

greater, and to this difference the sign of the greater must be annexed, with the common letter or letters.

Thus let it be required to add  $7a - 3a + 4a + 5a - 6a - 2a$  and  $9a$ ;  $25a$  will be found the sum of the positive terms, and  $11a$  that of the negative;  $11a$  being the less number, must therefore be subtracted from  $25a$ , the greater, leaving a remainder of  $14a$ , which is the required amount. The reason of this mode of procedure may be shown by a simple illustration:—As a letter may represent any quantity, let  $a$  represent £5; and suppose that a gentleman has in one bank  $7a$ , or seven five pounds; in another bank  $4a$ , and in another  $9a$ , or nine five pounds: let us suppose, too, that his tailor's bill is  $6a$ , or six five pounds; his baker's  $3a$ , or three five pounds; and his butcher's  $2a$ , or two five pounds; it is evident that, to ascertain how much money is really his own, he must first compute the whole value of his property dispersed in the different banks, then the amount of the bills of his creditors, and then find the difference between the two sums by subtracting the less from the greater. When the aggregate of the positive terms is equal to that of the negative ones, the sum of the two quantities will be equal to 0: thus, if a man possesses £2000, and owes £2000, it is evident that when his debts have been deducted from his property, nothing will remain. Unlike quantities can only be added by collecting them in one line, and prefixing the proper sign of each; thus the sum of  $3a + 2b + 4c - 2d$  can only be rendered  $3a + 2b + 4c - 2d$ ; this will be evident by reflecting that different letters in the same algebraical expression always represent different quantities, which cannot of course be added into one sum unless their precise value be known. Thus the addition of  $a$  and  $b$  cannot be represented by  $2a$  or  $2b$ , because that would imply that  $a$  is equal to  $b$ , which it is not necessarily; neither could it be represented by  $ab$ , because  $ab$  denotes the multiplication of the two quantities; the only method, then, of expressing these sums is thus,  $a + b$ . When like and unlike quantities are mixed together, as in the following example, the like quantities must first be collected together according to the method above described, and all unlike quantities must be annexed in order:—

$$\begin{array}{r} 9a + 5xy - 8ay \\ - 8xy - 10x + 2xy \\ 3x - 7ay - 5x \\ 5ax - 6ax + 11y \\ - xy - 4a + 9ax \\ 2ay + 12x - 2a \\ - 10y - 3xy + 13ay \\ \hline 3a - 8ax - 5xy + y \end{array}$$

**Subtraction.**

When two like quantities, having like signs, are to be subtracted the one from the other, the process is precisely the same as that already described in Arithmetic: thus,  $3a$  subtracted from  $7a$ , leaves a remainder  $4a$ . From  $8a + 5a$  take  $6a + 2a$ , and the remainder will be  $2a + 3a$ , or  $5a$ .

But supposing it were required to subtract  $6a - 4a$  from  $9a$ , it is evident that some other process must be adopted; because if  $6a$  be subtracted from  $9a$ , the proposed operation will not be performed; for it is not  $6a$ , but  $6a - 4a$ , that is,  $2a$ , which is required to be subtracted from  $9a$ ;  $6a$  subtracted from  $9a$  leaves  $3a$ , which is  $4a$  less than would result from subtracting  $2a$  from  $9a$ ; but if to  $3a$  we add the other term—namely,  $4a$ —the sum will be the remainder sought, because  $3a + 4a = 7a$ ; and if  $2a$  be subtracted from  $9a$ , which is just the same question in another form, for  $6a - 4a$  is  $2a$ , the remainder is just  $7a$ , as before. So if  $a - b$  is to be subtracted from  $c$ , the remainder would be  $c - a + b$ , and for the same reason. It may therefore be given as a general rule, that all the signs of a quantity which is required to be subtracted from another, must be changed: thus when  $4x - 3y$  is subtracted from  $7a + 5b$ , the remainder is written thus,  $7a + 5b - 4x + 3y$ .

When like quantities are to be subtracted from each other, it is usual to place them in two rows, the one above the other; the signs of the quantities to be subtracted must, for the reason above adduced, be conceived to be changed; and the several quantities must be added, as shown in the following examples:—

$$\begin{array}{r} \text{From } 5ax + 7xy - 2y \\ \text{Take } 3y + 3ax - 6xy \\ \hline \text{Remainder, } 2ax + 13xy - 5y \end{array}$$

**Multiplication.**

The multiplication of two quantities is performed by multiplying, as in arithmetic, the coefficients of the quantities, and then prefixing the proper sign and annexing letters: thus the product of  $3a$ , multiplied by  $5b$ , is  $15ab$ , and  $7a \times 4ab = 28a^2b$ .

When the signs of both quantities are alike, the sign + is to be prefixed; but when unlike, the sign - must be prefixed, which may be thus shown at one view:—

1. + multiplied by + produces +
2. - multiplied by - produces +
3. + multiplied by - produces -
4. - multiplied by + produces -

Hence the technical rule generally given is, that 'like numbers produce plus +, and unlike produce minus -.' This, however, is not perfectly true when more than two quantities are to be successively multiplied; because, although the product of an even number of negative quantities is positive, yet the product of an odd number of negative quantities is always negative; thus,

$$\begin{array}{l} -a \times -b \times -d = -abd \\ \text{and } -a \times -b \times -d \times -e = abde \end{array}$$

When the same letter occurs in both quantities, the indices must be added; thus,  $a^2 \times a^3 = aaaaa = a^5$ . In the multiplication of compound quantities, it is usual to commence from the left-hand figure; the multiplication, for instance, of  $8ab - 4ac + x$  by  $2a$ , is thus performed:—

$$\begin{array}{r} 8ab - 4ac + x \\ 2a \\ \hline 16a^2b - 8a^2c + 2ax \end{array}$$

To multiply two compound quantities, each term of the one must, as in arithmetic, be multiplied by each term of the other; these particular or partial products must be added according to the rules of addition, and their sum will give the whole product, as shown in the following instance:—

$$\begin{array}{r} \text{Multiply } 3a + 8b \\ \text{By } a - b \\ \hline 3a^2 + 8ab \\ - 3ab - 8b^2 \\ \hline \text{Product, } 3a^2 + 5ab - 8b^2 \end{array}$$

**Division.**

The operations of division being in algebra, as in arithmetic, merely the converse of those of multiplication, the same rules respecting signs apply in both. Thus,  $6ab^2$ , divided by  $2b$ , is equal to  $3ab$ ,

$$\text{And } -8ax^3 \div 4x, \text{ or } -\frac{8ax^3}{4x} = -2ax^2$$

In division, all letters common to both quantities must be omitted in the quotient; and when the same letters occur in both with different indices, the index of the letter in the divisor must be subtracted from that in the dividend; thus,

$$\begin{array}{l} abx \div ab, \text{ or } \frac{abx}{ab} = x; \text{ and} \\ 6a^5 \div 2a^2, \text{ or } \frac{6a^5}{2a^2} = 3a^3 \end{array}$$

When the exponent of any letter in the divisor exceeds that of the same letter in the dividend, the latter exponent must be subtracted from the former, and the quotient will be in the form of a fraction; thus,

$$-12a^2x^2 \div 8ax^5 = -\frac{12a^2x^2}{8ax^5} = -\frac{3a^2}{2x^3}$$

When the number to be divided is a compound quantity, and the divisor a simple one, then each term of the dividend must be divided separately, and the result will be the answer; thus,

$$\frac{6a + 24ab + 8a^2 + 12ac}{2a} = 3 + 12b + 4a + 6c$$

When the divisor and dividend are both compound quantities, the rule is the same as that of long division in arithmetic. When there is a remainder, it must be made the numerator of a fraction, under which the divisor must be put as the denominator; this fraction must then be placed in the quotient, as in arithmetic. The compound quantities must, however, be previously arranged in a particular way—namely, according to the descending powers of some letter, as of  $b$  in the following example; and this letter is called the *leading* quantity. The following is an example of the division of compound quantities:—

$$\begin{array}{r} b-x \overline{) b^3 - 3b^2x + 3bx^2 - x^3} \phantom{+ 2bx^2} \\ \underline{b^3 - b^2x} \phantom{+ 2bx^2} \\ \phantom{b^3 -} 2b^2x + 3bx^2 \\ \underline{\phantom{b^3 -} 2b^2x + 2bx^2} \\ \phantom{b^3 -} \phantom{2b^2x +} bx^2 - x^3 \\ \phantom{b^3 -} \phantom{2b^2x +} \underline{bx^2 - x^3} \\ \phantom{b^3 -} \phantom{2b^2x +} \phantom{bx^2 -} 0 \end{array}$$

Fractions.

The rules regulating the management of fractions in algebra are similar to those in arithmetic.

A mixed quantity is reduced to a fraction by multiplying the whole or integral part by the denominator of the fraction, and annexing the numerator with its proper sign to the product; the former denominator, if placed under this sum, will give the required fraction.

Thus the mixed quantity  $2x + \frac{5ab}{6e}$  may be thus reduced to a fraction:  $2x \times 6e = 12ex$ , and as  $5ab$  must be added to form the numerator, and the former denominator be retained, the required fraction is the following:  $\frac{12ex + 5ab}{6e}$ . An operation exactly the reverse

of this would of course be requisite were it proposed to reduce a fraction to a mixed quantity. Thus the fraction

$\frac{12ex + 5ab}{6e}$  may be reduced to a mixed number

by dividing the numerator by the denominator; the numerator of the fractional part must be formed by that term which is not divisible without a remainder; the following is therefore the required mixed quantity:

$2x + \frac{5ab}{6e}$ . A fraction is reduced to its lowest terms,

in algebra as in arithmetic, by dividing the numerator and denominator by any quantity capable of dividing them both without leaving a remainder. Thus in the

fraction  $\frac{10a^3 + 20ab + 5a^2}{35a^2}$ , it is evident that the

coefficient of every term can be divided by 5, and as the letter  $a$  enters into every term,  $5a$  may be called the greatest common measure of this fraction, because it can divide both the numerator and the denominator. The numerator  $(10a^3 + 20ab + 5a^2) \div 5a = 2a^2 + 4b + a$ ; and the denominator,  $35a^2 \div 5a = 7a$ ;

hence the fraction, in its lowest terms, is  $\frac{2a^2 + 4b + a}{7a}$ .

Sometimes the greatest common measure of two quantities is not so obvious as in the example just adduced, in which case recourse must be had to the following operation:—The quantity, the exponent of whose leading letter in the first term is not less than that in the other, must first be divided by the other; the divisor must then be divided by the remainder; each successive remainder is made the divisor of the last divisor, until nothing remains; when the divisor last used will be the greatest common measure. Quantities which have no common measure or divisor except 1, are called *incommensurable*; thus 7, 5, 3, and 11, are incommensurable quantities, and are also

said to be *prime* to each other. When fractions are required either to be added or to be subtracted, they must necessarily be first reduced to a common denominator, which is effected by multiplying each numerator by every denominator but its own, to produce new numerators, and all the denominators together for the common denominators. The new numerators can then be either added or subtracted according as the case may require, and the new denominator must be left unchanged. Multiplication of fractions is performed by multiplying all the numerators together for a new numerator, and their denominators together for a new denominator; it is then usual to reduce the resulting fraction to its lowest terms. Division of fractions is effected by multiplying the dividend by the reciprocal of the divisor. The reciprocal of any quantity is unity, or 1 divided by that quantity, or simply

that quantity inverted: thus the reciprocal of  $a$  or  $\frac{a}{1}$

is  $\frac{1}{a}$ , and the reciprocal of  $\frac{a}{b}$  is  $\frac{b}{a}$ ; therefore to divide

a fraction as  $\frac{8a^2}{2}$  by  $\frac{4a}{5}$ , the dividend  $\frac{8a^2}{2}$  must

be multiplied by the reciprocal of  $\frac{4a}{5}$ , which is  $\frac{5}{4a}$ ;

therefore  $\frac{8a^2}{4} \times \frac{5}{4a} = \frac{40a^2}{16a}$ ; this last fraction, divided

by its greatest common measure  $8a$ , is the fraction required—namely,  $\frac{5a}{2}$ .

Involution and Evolution.

The raising of a quantity to any required power is called involution, and is performed by multiplying the quantity into itself as often as is indicated by the given power. When the quantity has no index, it is only necessary to place the given power above it, in order merely to indicate the power: thus the fourth power of  $a$  is  $a^4$ , and the cube or 3d power of  $a + b$  is  $(a + b)^3$ .

When the quantity has an index, that index must be multiplied by the given power: thus the 4th power of  $a^2$  is  $a^8$ , because  $2 \times 4 = 8$ . If the quantity required to be raised be a fraction, both the numerator and the denominator must be multiplied by the given power:

thus the square of  $\frac{a^2}{a^3}$  is  $\frac{a^4}{a^6}$ . When the sign of the

quantity is +, then all the powers to which it can be raised must be +; if —, then all the even powers will be +, and all the odd powers —. Thus  $x \times x = x^2$ ;  $-a \times -a = a^2$ ;  $-a \times -a \times -a = -a^3$ .

A compound quantity—that is, one consisting of more than one term—is raised to any given power by multiplying it into itself the number of times denoted by the power. This is done according to the method already described in multiplication. Thus the square of  $x + 4y$ , is thus found:—

$$\begin{array}{r} \text{Multiply } x + 4y \\ \text{By } \phantom{x +} 4y \\ \hline x^2 + 4xy \\ \phantom{x^2 +} 4xy + 16y^2 \\ \hline \end{array}$$

$$\text{Square} = x^2 + 8xy + 16y^2$$

The operations of evolution are the reverse of those of involution, being designed to discover the square root, cube root, &c. of any given quantity. The roots of numerical coefficients are found as in arithmetic: thus the square root of 49  $a^2$ , is 7  $a$ , because  $7 \times 7 = 49$ . The index of the given quantity must be divided by 2 for the square root, by 3 for the cube root, by 4 for the 4th root, &c.: thus the cube root of  $a^6$  is  $a^2$ .

The square root of compound quantities may be extracted by a method very similar to that described in arithmetic, and of which an example was there given. The cube root may likewise be extracted by a similar process.

Irrational Quantities, or Surds.

Some numbers have no exact root; for instance, no

number multiplied into itself can produce 5. The roots of such quantities are expressed by fractional indices, or by the sign  $\sqrt{\quad}$ , which is called the radical sign, from the Latin *radix*, a root: thus the square root of 5, and the cube root of  $(a + b)^3$ , may be expressed either by  $\sqrt{5}$ ,  $\sqrt[3]{(a + b)^3}$ , or by  $5^{\frac{1}{2}}$ ,  $(a + b)^{\frac{1}{3}}$ .

The approximate value of such quantities can be ascertained to any required degree of exactness by the common rules for extracting roots: thus the square root of 2 is 1 and an indefinite number of decimals; but as the exact value can never be determined, the name of *irrational* is given to such quantities, to distinguish them from all numbers whatever, whether whole or fractional, of which the value can be found, and which are therefore termed *rational*. Irrational numbers are generally called *surds*, from the Latin *surdus*, deaf or senseless.

**Equations.**

When two quantities are equal to each other, the algebraical expression denoting their equality is called an *equation*. Thus  $x - 2 = 4 + 3$  is an equation, denoting that if 2 be deducted from some unknown quantity represented by  $x$ , the remainder will be equal to  $4 + 3$ , that is, to 7; therefore the value of  $x$  in this equation is evidently  $7 + 2$ , or 9.

The doctrine of equations constitutes by far the most important part of algebra, it being one of the principal objects of mathematics to reduce all questions to the form of equations, and then to ascertain the value of the unknown quantities by means of their relations to other quantities of which the value is known.

Many problems, which are now quickly and readily determined by being reduced to equations, used formerly to be solved by tedious and intricate arithmetical rules; and they may still be found in old treatises on arithmetic, arranged under the titles of Double and Single Position, False Position, Alligation, &c. Equations receive different names, according to the highest power of the unknown quantities contained in them. An equation is said to be *simple*, or of the *first degree*, when it contains only the first power of the unknown quantity: thus  $x + b = 35$   $a - 2$  is a simple equation, the unknown quantity being represented by  $x$ , as it generally is in other equations, and the known quantities by the other letters and figures.  $x^2 + 4 = 8$   $a$ , is a *quadratic* equation, because  $x$ , the unknown quantity, is raised to the second power.

$x^3 = a + 3 b$  is a *cubic* equation, the unknown quantity being raised to the third power.

$x^4 - a = 25$   $c$  is a *biquadratic* equation, because  $x$  is raised to the 4th power. If equations contain unknown quantities raised to the 5th, 6th, or higher powers, they are denominated accordingly.

The quantities of which an equation is composed, are called its *terms*; and the parts that stand on the right and left of the sign  $=$ , are called the *members* or *sides* of the equation.

When it is desired to determine any question that may arise respecting the value of some unknown quantity by means of an equation, two distinct steps or operations are requisite; the first step consists in translating the question from the colloquial language of common life into the peculiar analytical language of the science. The second step consists in finding, by given rules, the answer to the question, or in other words, the solution of the equation. Expertness and facility in performing the former operation cannot be produced by any set of rules; in this, as in many other processes, practice is the best teacher. Every new question requires a new process of reasoning; the conditions of the question must be well considered, and all the operations, whether of addition, subtraction, &c., which are required to be performed on the quantities which it contains, are to be represented by the algebraic signs of  $+$ ,  $-$ , &c.: the whole problem must be written down as if these operations had been already performed, and as if the unknown quantities were discovered, which can be done very briefly by substituting

the first letters of the alphabet for the known quantities, and the last letters for the unknown, prefixing to each the signs of addition, multiplication, &c. which may be denoted in the question. Thus suppose a farmer wished to divide £1, 15s. between his two sons, allowing 9s. more to the elder than to the younger, what would each receive! To express this question in algebraic language, the share of the younger son may be represented by  $x$ , and then that of the elder son will be  $x + 9$ . The steps of reasoning by which this question may be solved, are the following:—The share of the elder + the share of the younger is £1, 15s., equal to 35s.; therefore  $x + 9 + x = 35$ , or  $2 x + 9 = 35$   $\therefore 2 x = 35 - 9$ , or  $2 x = 26$   $\therefore x$  (share of the younger son)  $= \frac{26}{2} = 13$ , and  $x + 9$  (the share of the elder son),  $= 13 + 9 = 22$ .

The second operation in determining a question may be said to consist in contrivances to get  $x$ , or the unknown quantity, to stand alone on one side of the equation, without destroying the equality or balance between the two sides; because in such an equation, for instance, as the following,  $x = 4 + 2$ , the value of  $x$  is at once seen; if 6 were to be put in the place of  $x$ , the equation would be said to be *fulfilled*, because then it would stand thus,  $6 = 6$ ; therefore 6 is the *root* or solution of the equation,  $x = 4 + 2$ . In some questions, the unknown quantity is so much involved with known quantities, that it is often a difficult, although always a highly-interesting process, to separate it from them. Many rules for effecting this are given in most algebraical treatises, but they may all be comprised in one general observation—namely, that any operation, whether of addition, subtraction, &c. may be performed on one side of an equation, provided only that the very same operation be performed on the other side, so as not to destroy their equality. Thus in the equation  $x + 5 = 12$ , it is evident that if 5 could be removed from the left to the right side of the equation,  $x$  would stand alone, and its value at once be ascertained; it having been already stated that any operation may be performed on one side of the equation, provided only the same operation be performed on the other, it follows that 5 may be subtracted from the left side, if subtracted likewise from the right; therefore  $x + 5 - 5 = 12 - 5$ ; but  $5 - 5$  being equal to 0, the equation would more properly be expressed thus,  $x = 12 - 5$ ; that is to say, the value of  $x$  is 7. Again, in the equation  $x - 10 = 27$ , add 10 to each side of the equation; then  $x - 10 + 10 = 27 + 10$ ; but  $-10 + 10 = 0$ ; therefore  $x = 27 + 10$ . When the same quantity is thus subtracted from both sides of an equation, or added to both sides, the operation is technically, though perhaps incorrectly, termed '*transposing*' quantities from one side of an equation to the other.

The reason why the same operation performed upon both sides of an equation does not alter their equality, is simply because 'if equal quantities be added to, or subtracted from, equal quantities, the value of the quantities will still be equal.' To illustrate this—supposing a wine-merchant has 2 casks of wine, each cask containing 36 gallons, it is evident that if he draws off the same number of gallons from each cask, the quantity of gallons remaining in each cask will still be equal; so, if he were to replace the same number of gallons of wine in each cask, the number of gallons contained in each would still be equal to each other. For the same reason, if the two sides of an equation were either multiplied or divided by the same number, their equality to each other would still remain: in the equation  $3 x = 27$ , the value of  $x$  may be discovered by dividing both sides of the equation by its coefficient 3; thus  $\frac{3 x}{3} = \frac{27}{3}$ ; but  $\frac{3 x}{3} = x$ , and  $\frac{27}{3} = 9$ ;  $\therefore x = 9$ . In the same way, if the unknown quantity in an equation is required to be divided by some known quantity, each side of the equation may be multiplied by the divisor.

Thus in the equation  $\frac{x}{4} = 32$ , if each member be multiplied by 4, the result will be  $x = 32 \times 4 = 128$ . This is technically called clearing an equation of fractions.

On Simple Equations Containing two or more Unknown Quantities.

It may be given as a general rule, that when a question arises as to the value of two or more unknown quantities, each of these quantities must be represented by one of the last letters of the alphabet, and as many separate equations must be deduced from the question as there are unknown quantities. A group of equations of this kind is called a *system of simultaneous equations*.

If it be required to solve a system of two simple equations, containing two unknown quantities, the most natural method seems to be to determine first the value of one of the unknown quantities by means of both the equations. Then as 'things which are equal to the same thing are equal to each other,' it follows that the two sets of numbers or letters in the two equations, which have been ascertained to be equal to the value of  $x$ , will also be equal to each other, and may be reduced to an equation, which will contain only one unknown quantity. This process is technically called *diminution*. Let it, for instance, be required to find the length of two planks of wood: the length of both planks together is 20 feet, and one plank is 8 feet longer than the other plank. This is evidently a question involving two unknown quantities—namely, the length of each of the two planks of wood. To translate this question into algebraical language, call the longer plank  $x$ , and the shorter plank  $y$ , then the facts above-mentioned may be thus stated:  $x + y = 20$ , and  $x - y = 8$ . The value of  $x$  may be ascertained by means of both the equations in the following manner:—

The first equation gives  $x = 20 - y$   
 And the second,  $x = 8 + y$

The two values of  $x$ , thus ascertained, must form a new equation, thus:—

$$20 - y = 8 + y$$

$$20 = 8 + 2y$$

So that it is evident from this last equation, that 2  $y$  is equal to 12, because  $20 - 8 = 12$ ; therefore  $y = 6$ , and  $20 - 6 = 14$ . The length of both the planks is thus ascertained, the longer being 14 feet in length and the shorter 6 feet.

This problem is not only given as an example of *diminution*, but also as an illustration of the general theorem, that 'the greater of two numbers is equal to half their sum, plus half their difference; and that the less number is equal to half the sum, minus half the difference.' Thus the above question might have been solved in the following manner:—

$$\frac{20}{2} + \frac{8}{2} = 14, \text{ and } \frac{20}{2} - \frac{8}{2} = 6$$

The following is the method of demonstrating this curious theorem algebraically:—Let  $a$  and  $b$  be any two numbers of which  $a$  is the greater, and let their sum be represented by  $s$ , and their difference by  $d$ ;

Then  $a + b = s$   
 and  $a - b = d$

$$2a = s + d$$

$$\text{and } a = \frac{s + d}{2}$$

$$\text{Also } 2b = s - d$$

$$\text{and } b = \frac{s - d}{2}$$

Quadratic Equations.

A quadratic equation literally means a *squared equation*, the term being derived from the Latin *quadratus*, squared; a quadratic equation, therefore, is merely an equation in which the unknown quantity is squared or raised to the second power. Quadratic equations are often called equations of two dimensions, or of the second

degree, because all equations are classed according to the index of the highest power of the unknown quantities contained in them.

There are two kinds of quadratic equations—namely, pure and affected. *Pure* quadratic equations are those in which the first power of the unknown quantity does not appear: there is not the least difficulty in solving such equations, because all that is requisite is, to obtain the value of the square according to the rules for solving simple equations, and then, by extracting the square root of both sides of the equation, to ascertain the value of the unknown quantity. For instance, it is required to find the value of  $x$  in the equation  $x^2 + 4 = 29$ . By deducting 4 from each side of the equation, the value of  $x^2$  is at once seen to be as follows:  $x^2 = 29 - 4 = 25$ ; the square root of both sides of this equation will evidently give the value of  $x$ , thus  $x = \sqrt{25} = 5$ . *Affected* or *affected* quadratic equations are such as contain not only the square, but also the first power of the unknown quantities.

There are two methods of solving quadratic equations; we are indebted to the Hindoos for one of these methods, of which a full account is given in a very curious Hindoo work entitled 'Bija Ganita.' The other method was discovered by the early Italian algebraists. The principle upon which both methods are founded is the following:—It is evident that in an affected equation, as, for instance,  $ax^2 + bx = d$ , the first member,  $ax^2 + bx$ , is not a complete square; it is, however, necessary for the solution of the equation that the first side should be so modified as to be made a complete square, and that, by corresponding additions, multiplications, &c. the equality of the second side should not be lost; then by extracting the square root of each side, the equation will be reduced to one of the first degree, which may be solved by the common process.

The following illustration from Bridge will perhaps tend more to simplify the subject, and show its practical utility, than any mere abstract rules which might be advanced. A person bought cloth for £33, 15s. which he sold again at £2, 8s. per piece, and gained by the bargain as much as one piece cost him. Required the number of pieces.

Let  $x$  = the number of pieces, £33, 15s.  $\times 20 = 675$ ;

therefore  $\frac{675}{x}$  = the number of shillings each piece cost, and  $48x$  is equal to the number of shillings for which he sold the *whole*, because £2, 8s. or 48 shillings was the price he obtained for each piece. Therefore  $48x - 675$  was what he gained by the bargain.

Hence, by the question,  $48x - 675 = \frac{675}{x}$ . This equation, after having been submitted to the usual operations of transposition and division which have been already described, assumes the form of

$$x^2 - \frac{225}{16}x = \frac{225}{16}$$

The next step is to complete the square; this is done by adding to each side of the equation the square of half the coefficient of the second term.

$$x^2 - \frac{225}{16}x + \left(\frac{225}{32}\right)^2 = \frac{225}{16} + \frac{50625}{1024} = \frac{65025}{1024}$$

then extracting the square root,

$$x - \frac{225}{32} = \frac{225}{32} \text{ and } x = \frac{480}{32} = 15.$$

Therefore 15 pieces of cloth was the quantity sold.

It is often requisite, for the more easy solution of equations, to change them into other equations of a different form, but of equal value; and this is technically termed Transformation. Our limits will not permit us to enter on any explanation of this rule, or of the rules farther advanced in the science, as Permutations, Undetermined Coefficients, Binomial Theorem, Exponential Equations, &c. To those who desire to possess a more extensive knowledge of Algebra, we refer to the complete and accessible treatise of Mr Bell, in CHAMBERS'S EDUCATIONAL COURSE.

# GEOMETRY.

GEOMETRY (from two Greek words signifying the *earth* and *to measure*) is that branch of mathematical science which is devoted to the consideration of form and size, and may therefore be said to be the best and surest guide to the study of all sciences in which ideas of dimension or space are involved. Almost all the knowledge required by navigators, architects, surveyors, engineers, and opticians, in their respective occupations, is deduced from geometry and other branches of mathematics. All works of art are constructed according to the rules which geometry involves; and we find the same laws observed in the works of nature. The study of mathematics, generally, is also of great importance in cultivating habits of exact reasoning; and in this respect it forms a useful auxiliary to logic. As will be observed even from the short sketch which we are able to present, the steps of reasoning from given and exact premises are clear and undeniable, and the results satisfactory. All subjects, it is true, are not susceptible of being brought to the test of mathematical analysis; but to one acquainted with the process, no fantastic speculations or loose points in any argument will be accepted as proved truths, or passed over without an attempt at refutation. 'The student of mathematics,' says Dr Whewell, 'is accustomed to a chain of deduction, where each link hangs upon the preceding; and thus he learns continuity of attention and coherency of thought. His notice is steadily fixed upon those circumstances only in the subject on which the demonstrativeness depends; and thus that mixture of various grounds of conviction, which is so common in other men's minds, is rigorously excluded from his. He knows that all depends upon his first principles, and flows inevitably from them; that however far he may have travelled, he can at will go over any portion of his path, and satisfy himself that it is legitimate; and thus he acquires a just persuasion of the importance of principles on the one hand, and on the other of the necessary and constant identity of the conclusions legitimately deduced from them.'

It has been frequently asserted, though apparently with little truth, that geometry was first cultivated in Egypt, in reference to the measurement of the land. Thales of Miletus, who lived about 600 B.C., is among the first concerning whose attainments in mathematical knowledge we have any authentic information. About two centuries later, the Platonic school was founded, which event is one of the most memorable epochs in the history of geometry. Its founder, Plato, made several important discoveries in mathematics, which he considered the chief of sciences. A celebrated school, in which great improvement was made in geometry, was established about 300 B.C. To this school the celebrated Euclid belonged. After this period geometrical science, like all general knowledge, gradually declined; and such continued to be the case until about a century after, when it revived among the Arabians.

About the beginning of the fifteenth century geometry, as well as all other departments of knowledge, became more generally cultivated. In modern times, Kepler, Galileo, Tacquet, Pascal, Descartes, Huygens of Holland, our own Newton, Maclaurin, Lagrange, and many others, have enlarged the bounds of mathematical science, and have brought it to bear upon subjects which, in former ages, were considered to be beyond the grasp of the human mind.

As improved by the labours of mathematicians, geometrical science now includes the following leading departments:—Plane Geometry, the basis of which is the Six Books of Euclid's Elements; Solid and Spherical Geometry, Spherical Trigonometry, the Projections of the Sphere, Perpendicular Projection, Linear Per-

spective, and Conic Sections. But to these main branches of the science there are added Practical Mathematics, which may be defined as an elaboration of the abstract doctrines and rules of general mathematics in application to many matters of a practical nature in the business of life. For example, among the branches of Practical Mathematics we find Practical Geometry, Trigonometry, Measurement of Heights and Distances, Levelling, Mensuration of Surfaces, Mensuration of Solids, Land-Surveying, Calculations of Strength of Materials, Gauging, Projectiles, Fortification, Astronomical Problems, Navigation, Dialling, &c. In such a limited space as the present sheet it would be altogether impossible to present even a mere outline of these numerous branches of general and practical mathematics; and all we propose to do is, to offer a sketch of a few leading features of the science, in order to show what is meant by various terms in common use, and also to incite the reader to a regular course of study.

## DEFINITIONS OF TERMS AND FIGURES.

In common language, the extremity of any sharp instrument, such as an awl, a pencil, or a penknife, is called a point. A small mark or dot made with such an instrument on wood or paper would also be called a point; but if examined with a magnifying-glass, it would appear an irregular spot, having length and breadth. A *geometrical point*, on the contrary, has neither length nor breadth, and may be called an imaginary dot.

The extremities or ends of lines are always considered to be points; and when two lines intersect—that is, cross each other—the intersection is called a point.

The definition always given in geometry of a *line* is, that it is *length without breadth*. It is therefore evident that a true geometrical line cannot be constructed; for however finely a line may be drawn, it will be always found to have some breadth; this will at once appear by examining it through a microscope.

In practical geometry it is necessary to draw points and lines; but it is impossible to approach to mathematical exactness unless they be drawn as finely as possible—always bearing in mind that such lines and points are merely *symbols* of the true geometrical lines and points to which our reasoning refers.

A *superficies* or *surface* has only length and breadth, and is bounded by lines. By the word surface is generally understood the outside of anything; as, for instance, the exterior of the lid or of the sides of a box. It is also used in geometry to convey the very same idea, always supposing that it has no thickness.

A *geometrical surface*, like a line and a point, cannot be constructed. The thinnest sheet of paper is not a superficies, but a solid, having the three kinds of bulk technically called dimensions, which are possessed by a solid body—namely, length, breadth, and thickness.

*Solids* are bounded by surfaces. Geometry considers the dimensions of space as abstracted or separated from any solid body which might occupy that space: a body always occupies a space exactly equal to itself in magnitude. This will be better understood by imagining a cast to be taken of some solid body: when the body is removed, a cavity remains, and we can reason concerning the dimensions of that cavity, knowing that it is of the same length, breadth, and thickness, as the solid body from which it was cast. In this way we reason concerning the dimensions of any given space, and with the same precision as if geometrical lines, surfaces, and solids, were really drawn in that space; and it is the business of theoretical geometry to examine the properties and relations of these forms or magnitudes. We learn from practical geometry how to form representations of the ideas thus acquired. Therefore

the common meaning usually attached to the words *point*, *line*, *surface*, and *solid*, is admissible in practical geometry; the object of this branch of science being to show how to draw upon paper, or construct in wood or metal, correct representations of those forms or magnitudes which are conceived to exist in space.

As there are three kinds of magnitudes—lines, surfaces, and solids—it follows that the natural division of the science of geometry is into three primary departments—namely, 1. Geometry of Lines; 2. Geometry of Surfaces; 3. Geometry of Solids, or Solid Geometry. The term *Plane Geometry*, however, is usually applied to the geometry of straight lines, rectilinear figures, and circles described on a plane.

Lines are named by two letters placed one at each extremity. Thus the line drawn here  is named the line A B.

It is obvious that lines can be drawn in different ways and in various directions. A line can be crooked, curved, mixed, convex, concave, or straight.

1. A *crooked* line is composed of two or more straight lines.

2. A line, of which no part is a straight line, is called a *curved line*, *curve line*, or *curve*.

3. A *mixed line* is a line composed of straight and curved lines.

4. A *convex* or *convex* line is such that it cannot be cut by a straight line in more than two points; the *concavity* of the intercepted portion is turned towards the straight line, and the *convexity* from it.

A straight line is in geometry called a *right* line, from the Latin *rectus*, straight. If two lines are such, that when any two points in the one touch or coincide with two points in the other, the whole of the lines coincide, each of them is called a *straight* or *right* line. Thus a line which has been carefully ruled on a sheet of paper will be found to coincide with the edge of a ruler.

A straight line, therefore, may be said to lie evenly between its extreme points. If a straight line, as A B, turn round  like an axis, its two extremities A and B remaining in the same position, any other point of it, as C, will also remain in the same position.

Any point in a line is called a *point of section*, and the two parts into which it divides the line are called *segments*. Thus the point C in the above line A B is a point of section, and A C, B C are segments.

It is evident that two straight lines cannot enclose a space; and that two straight lines cannot have a common segment, or cannot coincide in part without coinciding altogether.

A surface may be concave, like the inside of a basin; convex, like the exterior of a ball; or plane, like the top of a flat table. A plane superficies, or, as it is commonly called, a *plane*, is considered to be perfectly even, so that if any two points are taken in it, the straight line joining them lies wholly in that surface. This cannot perhaps be better illustrated than by placing two flat panes of glass the one above the other. If the two surfaces coincide exactly in every part, they may be said to form a geometrical plane; and it is upon a plane equally flat and even that all geometrical lines and figures in plane geometry are supposed to be drawn.

The Circle.

A figure is a part of space enclosed by one or more boundaries; if these boundaries are superficies, it is called a *solid*; and if lines, it is called a *plane* figure, in plane geometry.

The space contained within the boundary of a plane figure is called its *surface*; and the quantity of surface, in reference to that of some other figure with which it is compared, is called its *area*.

The circle is one of those figures which are most used in the arts and in practical geometry, and therefore

claims particular attention. When a line is made to turn round one of its ends or extremities which remains fixed, the extremity which is carried round the other traces a line which is in every part equally distant from the point where the other end is fixed. The line thus traced is a *circle*, and is frequently termed the *circumference*, from the Latin *circum*, round, and *ferens*, carrying.

A pair of compasses are generally used in practical geometry to describe a circle. They consist of two straight and equal legs, generally of brass or iron, and always pointed at the bottom. Their upper extremities are joined together by a rivet or joint, so that they can be opened or closed at pleasure. In order to draw a circle, one end must be firmly fixed, and the other, after being opened proportionately to the required size of the circle, must be made to turn completely round, and a pencil or pen being attached to it, the trace of the circle is left upon the paper. The point in which one of the legs of the compasses is fixed, and round which the circle is described, is called its *centre*, as A. A straight line, as A B, drawn from the centre to the circumference of a circle, is called a *radius*, which is a Latin word literally signifying a ray, and of which the plural is radii. A common wheel affords one of the most familiar examples of a circle. The axle is the *centre*, and the spokes are *radii*, while the outer rim of the wheel may be called the *circumference*. It is evident that all the spokes are of equal length; and this is invariably the case with the radii of every circle. A straight line, drawn through the centre of a circle, and terminated at each extremity by the circumference, is called a *diameter*, from the Greek *dia*, through, and *metreo*, I measure. Thus CD is a diameter of the preceding circle.

An *arc* of a circle is any part of the circumference, as a b c; the *chord* of an arc is a straight line joining its extremities, as a c. These two words come from the Latin words

*arcus*, a bow, and *chorda*, a string, because, as is shown by the annexed figure, a geometrical arc with its chord closely resembles a bow to which a string has been attached for the purpose of shooting. A rainbow is a beautiful example of an arc. A *semicircle* is a segment, having a diameter for its chord, and therefore is just half of a circle.

When a chord is lengthened, and made to extend beyond the boundaries of a circle, it is said to *cut* the circle, and is therefore called a *secant*, from the Latin *secans*, cutting.

A straight line, A B, which lies wholly *outside* the circle, meeting it only in one point, is called a *tangent*, from the Latin *tangens*, touching, because it is said to touch the circle in the point C. If the line A B were to remain fixed, and if the circle C D E were made to revolve round a point in its centre, in the same way, for instance, as a fly-wheel turns, it would be found that no part of the line A B would be touched by the circle, except the one point C. This property of the circle has been turned to account in various ways. Thus the grindstone used for sharpening knives is a circle made to revolve on its centre; the blade of the knife is held as a *tangent* to this circle; and therefore each time that the grindstone is turned round, it rubs against the blade, producing a finer edge, and giving it a polished appearance.

Circles are said to *touch* one another when they meet, but do not cut one another. Circles that touch one another, as the circle C D E and F G H in the last figure, are called *tangent* circles.

The point in which a tangent and a curve, or two

tangent circles meet, is called a *point of contact*. When of two tangent circles one is within the other, the contact is said to be *internal*; but when the one is without the other, the contact is said to be *external*. (See figure.) Tangent circles are very frequently applied to useful purposes in various arts and manufactures. The wheels of a watch are merely so many tangent circles. When, by means of the mainspring, one of the circles is made to revolve, its motion causes the wheel which touches it to move also, and the motion of that tangent circle causes the wheel which touches it to move likewise; and in this way motion is transmitted or carried through the watch. It will be observed, on examining the inside of a watch, that the circumference of each wheel is indented or toothed; when the watch is going, the teeth of one wheel enters into the indentations of the other, and thus the one wheel is carried round by the other.

*Concentric circles* are circles within circles, having the same centre, *c*. A stone thrown into water produces a familiar instance of concentric circles; the waves at first rush in to supply the place of that portion of water which was displaced by the stone, and then, by rapidly flowing back, several circles are formed, one within the other, on the surface of the water; and though these circles are of very various sizes, some being large, and others small, yet the spot in which the stone fell is alike the centre of all, and therefore they are called *concentric circles*.

Circles that have not the same centre are called *eccentric*, in reference to each other, from the Latin *ex*, out of, and *centrum*, centre. A point which is not the centre of a circle may also be called *eccentric* in reference to that circle.

Circles are called *equal* when their radii are equal in length, because it necessarily follows that the circumference is also equal: thus the two wheels of a gig are obviously equal circles, and the spokes or *radii* of one are equal to those of the other.

The circle, as we shall hereafter have occasion to show, is of much importance in many operations of practical geometry, and is therefore divided into 360 equal parts, called *degrees*. It would, however, have been possible to have divided the circle into any other number of degrees; the reason why the number 360 was originally fixed upon is the following:—During the early ages of astronomy the sun was supposed to perform an annual revolution round the earth, while the earth remained perfectly stationary. The first astronomers taught that the orbit or path in which they imagined the sun to move was a circle, and that the period which elapsed from the moment of his leaving one point in this circle until he returned to it again was precisely 360 days. Accordingly, all circles were divided into 360 degrees.

When it was discovered that the earth moves round the sun, and that she performs an entire revolution, not in 360 days, but in 365 days 6 hours 48 minutes 48 seconds, it was not thought advisable to alter the division of the circle which had previously been established, because the number 360 is found of great convenience in all lengthened calculations, there being many numbers by which it can be divided without a remainder, as 1, 2, 3, 4, 5, 6, 8, 9, 10, 12, 15, 20, &c.

Each of the 360 degrees is subdivided into 60 minutes, and each minute into 60 seconds. The degree is marked thus ( $^{\circ}$ ); the minute ( $'$ ); the second ( $''$ ); so that to express 14 degrees 7 minutes 5 seconds we have only to write  $14^{\circ} 7' 5''$ . Sometimes the second is again divided into sixty equal parts, called *tierces*, or thirds, which division is expressed by the sign ( $'''$ ); but more frequently decimals are used to express the smaller divisions.

The French divide the circle into 400 equal parts, called *degrees*; each degree into 100 minutes, and each minute into 100 seconds. When this division is used by English writers, they generally give the name of

*grades to the degrees*. One grade is equal to  $0^{\circ}.9$ , or to  $54'$ , or to  $3240''$ .

A circle, as we have just observed, being divided by mathematicians into 360 degrees or parts, it follows that the quarter of a circle includes 90 degrees. Taking, then, a quarter of a circle, and marking it as in the adjoining figure, HL is the horizontal line, and PL the perpendicular line ascending from it. Any line drawn from the centre to any point of the circumference defines the degree of inclination, or slope off the horizontal.

Thus a line ascending from the centre to the 10th degree, is called an inclination or angle of ten degrees; a line ascending to the 45th degree is called an inclination or angle of forty-five degrees; and so on with all the other degrees to the 90th. In this manner a standard of comparison has been established for defining the various slopes or inclinations in planes.

**Angles.**

Every one is familiar with the meaning of the word *corner*; we are accustomed to call those parts of a room in which the walls meet the '*corners* of the room,' and in the same way, the sharp point in which two sides or edges of a table meet is also called a corner. The very same idea suggested by the word *corner* is admitted into geometry, only the word itself is dropped, and the word *angle* substituted, simply because the Latin for corner is *angulus*.

By an *angle*, therefore, we are to understand the inclination or opening of two straight lines that meet, but are not in the same straight line. The two lines which thus form an angle are called the *sides* of that angle. In the above figure of the quadrant, or quarter circle, we have an example of a right angle in the corner formed by the junction of the horizontal and upright lines.

An angle which is greater than a right angle, or more than 90 degrees (as O), is called an *obtuse angle*, from the Latin *obtusus*, blunt, because the vertex or angular point has a blunt appearance.

An angle which is less than a right angle, or less than 90 degrees (as A), is called an *acute angle*, from the Latin *acutus*, sharp, from the vertex being sharp-pointed. The number of degrees by which an obtuse angle exceeds, or by which an acute angle is less than a right angle, is called the *complement* of the angle.

The two lines which form a right angle are said to be *perpendicular* to each other; therefore, whenever a perpendicular is raised either on the ground or on paper, a right angle is formed. Thus the walls of houses and of all architectural edifices are perpendicular, and form right angles with the ground on which they are built; and when the perpendicular is departed from, as in the Leaning Tower of Pisa, the eye is offended, and an apprehension of danger excited in the mind. It is not, however, essential that a perpendicular line should be vertical—that is to say, in the same direction as a weight falls when suspended by a string: a perpendicular may be in an inclined, or even in a horizontal position, provided only that it form an angle of 90 degrees with the line to which it is perpendicular. It is so often requisite in practical geometry to erect a perpendicular, that an instrument called a Carpenter's Square has been invented for the purpose. It consists merely of two flat rulers placed at right angles to each other. As, however, instruments of this description are often made with great inaccuracy, and as it is not, besides, always possible in certain situations to have one

at hand, the following methods of raising a perpendicular on a given line, and from a given point, will be found very useful.

Let AB be the given line, and C the given point.

Case 1.—When the point is near the middle of the line.

On each side of C lay off equal distances, CD, CE; and from D and E as centres, with any radius, describe arcs intersecting in F; draw CF, and this is the required perpendicular.

Case 2.—When the point is near one of the extremities of the line.

Method 1.—From C as a centre, with any radius, describe the arc DEF, and from D lay off the same radius to E, and from E to F; then from E and F as centres, with the same or any other radius, describe arcs intersecting in G; draw GC, and it will be perpendicular to AB.

Method 2.—From any point D as a centre, and the distance DC as a radius, describe an arc ECF, cutting AB in E and C; draw ED, and produce it to cut the arc in F; then draw FC, and it is the perpendicular.

The angles made by a straight line falling on another straight line are either two right angles, or are together equal to two right angles. The first of the annexed figures presents an example of two right angles being formed by the meeting of two straight lines. In the second figure it is evident that the angle ACD contains exactly as many degrees more than a right angle as the angle DCB contains less than a right angle:

therefore the two angles are together equal to two right angles. Each of these angles is said to be the *supplement* of the other, from the Latin *suppleo*, 'I fill up what is deficient,' because the numerical value of each angle is exactly what the other wants of 180 degrees, which is the sum of two right angles. Equal angles have therefore invariably equal supplements; and it is scarcely necessary to add, that all angles having equal supplements must be equal.

From this it follows that when two straight lines cross, the opposite angles are equal. The angles AEC and DEB are called *vertical angles*, because they are opposite to each other; they are evidently equal, simply because they have equal supplements, as will at once be seen by a careful examination of the figure. The same is true of the angles CEB and AED. It is manifest from this, that if two straight lines cut one another, the angles which they make at the point of their intersection are together equal to four right angles. Hence all the angles made by any number of lines meeting in one point are together equal to four right angles.

Parallel Lines.

We are surrounded by familiar examples of lines which always preserve the same distance from each

other. The ruts made in a muddy road by the wheels of a cart, the iron bars called *rails* of a railway, upon which the wheels of the steam-carriages run, the five lines upon which the characters of music are drawn, the strings of a harp, &c. are all so many instances of lines which are always equidistant from each other; and which, even if prolonged to an infinite extent in the same direction, could never meet. Such lines are in geometry called *parallels*, from the Greek words *para*, beside, and *alleion*, each other.

As the distance between any two parallel lines is always equal at every point, it follows that perpendiculars drawn between such lines must also be equal. Thus in architecture, the columns which support the upper part of a building are made of equal height, because the roof which they support is parallel with the base from which they are erected. From the fact that parallel lines cut other lines proportionally, results a mode of dividing a given line into any number of given parts.

Let AB be the given line, and let the number of equal parts be five.

Method 1.—Draw a line AC through A at any inclination to AB, and through B draw another line BD parallel to AC; take any distance AE, and lay it off four times on AC, forming the equal parts AE, EF, FG, GH; lay off the same distance four times on BD in the same manner; draw the lines HI, GK, FL, and EM, and they will divide AB into five equal parts. For AB, AH, and BM are cut proportionally.

In this figure the lines AC and DB being parallel, the parallel lines EM, FL, &c., are equal; and by them the straight line AB is divided into equal parts. In practical geometry, the method of drawing a line parallel to a given line, and at a given distance from it, depends on the fact, that the parallel lines are everywhere equidistant, and is the following:—

Let KL be the given line, and D the given distance.

From any two points M and N in KL as centres, and a radius equal to D, describe the arcs P and Q; draw a line RS to touch these arcs—that is, to be a common tangent to them—and RS is the required line parallel to AB.

Triangles.

The triangle is one of the most useful figures in geometry: all figures which are bounded by straight lines are capable of being resolved or divided into triangles. A triangle has three sides, and also, as its name imports, three angles.

A triangle (as E) in which the three sides are equal, is called *equilateral*, from the Latin *aequus*, equal, and *latus*, a side. Such a triangle is also called *equiangular* (from *aequus*, equal, and *angulus*, corner), because when the sides of a triangle are equal, the angles likewise are invariably equal.

A triangle (as I) having two equal sides, is called *isosceles*, from the Greek *isos*, equal, and *skelos*, leg.

In a *scalene* triangle (as S) the three sides are of unequal length. The word *scalene* literally means unequal, being derived either from *skazo*, to limp, or from *skalenos*, unequal.

One of the most important properties of triangles is, that the three angles are together equal to two right angles. This fact is demonstrated in the following manner;—Draw a triangle, as ABC, and extend one of

its sides (BC) as far as D. The obtuse angle thus formed (ACD) is called an *exterior* angle, because it is outside the triangle. From the point C draw a straight line to E, parallel to the line AB. It is an established fact, that all alternate angles formed by a straight line cutting two parallel lines, are equal; the angles BAC, ACE are alternate, because they are formed by the straight line AC cutting the two parallel lines AB and CE, and are therefore equal. It is evident that the angles ABC and ECD are equal, because the line AB, which forms a side of one angle, is parallel to the line CE, which forms a side of the other; and the other side of each angle is made by the same line—namely, BD; and an angle being the inclination of one line to another, it is obvious that whenever, as in this case, the inclination of the lines is equal, the angles likewise must be equal. Having now proved that the obtuse exterior angle ACD is equal to the two interior and opposite angles CAB, ABC, we have merely to add ACB, the only remaining angle of the triangle, to the angle ACD; and the angles ACD, ACB will be found equal to the three angles CBA, BAC, ACB; but the angles ACD, ACB are equal to two right angles, because, as has been already stated, the angles made by one straight line falling upon another, are either two right angles, or are together equal to two right angles; therefore the angles CBA, BAC, ACB are equal to two right angles, or 180 degrees.

There are several very useful conclusions to be deduced from this property of triangles.

1. There can only be one right angle in a triangle; for if one angle is 90 degrees, the other angles can only be together equal to 90 degrees; one must be the complement of the other, or what the other wants of 90 degrees. A triangle which has a right angle is called a *right-angled* triangle, as R. The side opposite the right angle is called the *hypotenuse*.
2. It is equally obvious that a triangle cannot contain more than one obtuse angle. Fig. O is an *obtuse-angled* triangle.
3. All the angles of a triangle may be acute, as A, which is called an *acute-angled* triangle.
4. When two angles of a triangle are known, or even the sum of those angles, the third may be easily discovered; for if the sum of two angles be deducted from 180 degrees, the remainder must be the number of degrees of which the third angle consists.

Another property of triangles is, that the greater angle of every triangle has the greater side opposite to it. In the annexed triangle, the angle ABC is greater than the angle BCA. The side AC, being opposite to the larger angle, is longer than the side AB, which is opposite to the smaller angle. There is a kind of natural geometry in the mind even of an uneducated person, according to which he acts without much reflection. Supposing that an untaught peasant had to ascend to the summit of a mountain, he would not commence his ascent from a point where the mountain forms the greatest angle with the ground, and is therefore most precipitous; he would, on the contrary, take the more circuitous road along the opposite side of the mountain, as if he were aware of the property of triangles which has been last mentioned—namely, that the largest angles are subtended by the longest sides.

Quadrilateral Figures.

Quadrilateral, or literally four-sided figures, are sometimes called *quadrangles*, because they have four angles; they may be divided into two classes:—1. Those in which all the opposite sides are parallel; and, 2. Those in which all the opposite sides are not parallel.

Those belonging to the first class are called *parallelograms*, and may be farther subdivided into two divisions—namely, those which contain four right angles, and to which the generic name of *rectangle* has consequently been applied; and *secondly*, those which do not contain any right angles, two of the angles being obtuse and two acute.

A square is the most useful of quadrilateral figures. Having four right angles, it is called a *rectangle*; and all the sides are of equal length. The figure S is a square. The annexed figure R may be called with equal propriety a parallelogram, a rectangle, or an oblong; it will be observed that its sides are not all equal, its length being greater than its breadth. In speaking of a rectangle, it is often found convenient to name it by the lines which compose its base and height, and it is called the rectangle under or contained by these lines.

A *rhombus* or *lozenge*, and a *rhomboid*, form the second division of the first class; because, although the sides are parallel, the angles are not right angles. A rhombus has all its sides equal, as B. In a rhomboid, the opposite sides only are equal, as P; the length being either greater than the breadth, or *vice versa*.

A *trapezoid* has only two sides parallel, as D. When the sides of a trapezoid that are not parallel are equal, it is sometimes called a *trapezium*, from the Greek word *trapeza*, a table.

A *diagonal* is a straight line drawn between two opposite angular points of a parallelogram. A diagonal bisects a parallelogram—that is, divides it into two equal parts; thus let ACDB be a parallelogram, of which BC is a diagonal; the opposite sides and angles of the figure are equal to one another, and the diagonal BC bisects it.

From this it immediately follows, that the complements of the parallelograms, which are about the diagonal of any parallelogram, are equal to one another. It has been shown that the literal meaning of the term complement is to *fill up*; the application of this term to parallelograms will be understood by carefully comparing the following explanation with the annexed figure. Let ABCD be a parallelogram, of which the diagonal is AC; let EH, FG be the parallelograms about AC—that is, through which AC passes—and BK, KD the other parallelograms which make up the whole figure ABCD, which are therefore called the complements. The complement BK is equal to the complement KD. The two complements, joined to any of the parallelograms about a diagonal, form what is called a *gnomon*. Thus the parallelogram HG, together with the complements AF, FC, is the gnomon, which is more briefly expressed by the letters AGK, or EHC, which are placed at the opposite angles of the parallelograms which make the gnomon.

When it is required to describe a rectangle, of which the length and breadth are to be respectively equal to two given lines, the following operation is necessary:—

Let HI and KL be the given lines.

Draw a line MN equal to HI, and draw MP perpendicular to MN, and equal to KL; from P

as a centre, with a radius equal to MN, describe an arc at Q; and from N as a centre, with a radius equal to MP, describe an arc cutting the former in Q; draw PQ, NQ; and MQ is the required rectangle.

A square may, for practical purposes, be described in the following manner on any given line:—

Let MN be the given line.

From M draw MP perpendicular to MN, and from MP cut off a part MQ equal to MN; then from Q and N as centres, with a radius equal to MN, describe arcs intersecting in R; draw QR and NR, and MR\* is the required square.

The Ellipse.

An ellipse, or oval, is geometrically constructed as follows, by means of a pair of compasses:—Let AB be the major axis or transverse; draw a line bisecting it perpendicularly (which is done by describing from A and B as centres, with any radius, arcs cutting each other in C and D, and then joining C and D); and make GC, GD, each equal to half the minor axis or conjugate; then CD is the minor axis.

From C as a centre, with half the major axis AG as a radius, cut AB in E and F, and these points are the foci. Produce AB to Q, till EQ becomes equal to AB; and from E as a centre, with EQ as a radius, describe the arc PQR, and it will be a species of directrix to the ellipse. From the same centre E, with any distance EI, describe the arc HIK, and with IQ, the distance of this arc from PQR, as a radius, and F as a centre, cut the arc HIK in H and K, and these are two points in the curve. Similarly, from E as a centre describe another arc LM; and with the distance of this arc from PQR as a radius, and F as a centre, cut the arc LM in L and M, and these are also two points in the curve. Find the other two points S and T in exactly the same manner. Having thus found a sufficient number of points in the curve, join them all carefully, and the ellipse will thus be constructed.

An ellipse may be constructed by the following method, which will be considered sufficiently exact for many practical purposes:—

On a given line, as AB, describe two circles of such diameter as may best accord with the required proportions. Whatever size be taken, let the foot of the compasses be placed so as to describe the elongated parts of the figure true on the perpendicular line AB. Then draw a horizontal line so that it intersects the parts C and D, where the circles cut each other. Now the width of the oval may have been previously determined; if so, it must regulate the expansion of the compasses, and determine where the foot shall be placed on the line CD, equidistant from the centre, so as to describe the segment, that it may unite with the lines of the circles on either side, forming a continuous line, as at EE and FF; that is, in such a manner as to form the oval figure as if made by one operation.

\* Quadrilateral figures are concisely named, as above, by the letters at two opposite angular points.

Polygons.—Inscribed and Circumscribed Figures.

A plane figure enclosed by more than four straight lines, is called a polygon, from the Greek words *polus*, many, and *gonia*, an angle; because, when a figure has many sides, it has necessarily a corresponding number of angles. A regular polygon has all its sides equal, and also all its angles; an irregular polygon has its sides or angles, or both, unequal. A polygon of five sides is called a *pentagon*; of six, a *hexagon*; of seven, a *heptagon*; of eight, an *octagon*; of nine, a *nonagon*; of ten, a *decagon*; of eleven, a *undecagon*; of twelve, a *dodecagon*; and of fifteen, a *quindecagon* or *pentecagon*. Figures which have more than twelve sides are called polygons of 13, 14, 15, 16, 17 sides, &c.

The centre of a regular polygon is a point equally distant from its sides or angular points. The *apothem* is a perpendicular drawn from the centre to any one of the sides, and analogous to the radius of a circle.

The whole boundary of any figure is called its *perimeter*, from *peri*, around, and *metres*, I measure. The perimeter of a polygon is, in fact, what the circumference is in a circle, for by it the figure is enclosed.

In practical geometry, the usual method adopted for obtaining regular polygons is, in the first place, to draw a circle about equal in size to the required size of the polygon; then the circumference is divided into as many equal parts as the polygon is to have sides; all that then remains to complete the figure is to draw straight lines or chords between each two points of division, and these lines will form the sides of the polygon.

Figures constructed according to this method are said to be *inscribed* in a circle, and all the angles of the inscribed figure will always be found to be upon the circumference of the circle. A regular pentagon may, by the following process, be inscribed in a circle:—

Let SLR be the given circle.

Draw two perpendicular diameters, IK, LM; bisect the radius OI in N; from N as a centre, with NL as a radius, cut OK in P; with radius LP, and centre L, cut the circumference in Q; join LQ, and other four chords equal to it being drawn in succession in the circle, the required polygon will be formed.

A regular decagon may be inscribed in a circle by a little extension of the same process:—

Let SLR be, as before, the given circle.

Find a side LQ of the inscribed regular pentagon; bisect the arc LQ in V, and the chord LV being drawn, it is a side of the regular decagon; and ten chords equal to it being successively placed in the circle, will form the polygon.

Sometimes a figure is described about a given circle, and is then said to be a *circumscribed* figure, the circumference of the circle being touched by each of its sides. In practical geometry, the method of describing a regular polygon about a circle is the following:—

Let WVY be the given circle.

Find the angular points of the corresponding inscribed polygon of the same number of sides; let W, X, Y, be three of these angular points; through these points draw the tangents WU, UT, TY; and UT is a side of the required polygon; in the same man-

ner the other sides are found, and the circumscribing polygon is thus described.

In this manner the regular pentagon in the adjoining figure is described about the circle; H, K, L, M, and G, being the angular points of the inscribed regular pentagon, and tangents through these points being drawn, the circumscribing regular pentagon is formed.

Practical geometry affords a short and easy method of constructing a regular hexagon upon a given line.

Let GH be the given line.

From G and H as centres, with the radius GH, describe arcs intersecting in X, and this point is the centre of the circumscribing circle; hence with the radius GH, from the centre X, describe a circle, and apply GH six times along the circumference, then GHIKLM is the required hexagon.

Another fact relating to the properties of regular figures, and which is of some importance in several of the mechanical arts, is, that there are only three regular figures which can cover a surface completely, so as to leave no intervening interstices; these figures are the square, the equilateral triangle, and the hexagon: we have a familiar example of the fact that squares can completely cover a surface, in a common chess-board—the sides of each square coincide exactly with the sides of the adjoining squares, and no part of the board between the squares is left uncovered. The reason of this is, that all the angles made by any number of lines meeting in one point, are together equal to four right angles, or to 360 degrees; and that, therefore, if it be required to lay any number of figures together, so that the sides may be joined, and that no space may intervene between, it is a necessary condition that the angles contained between their sides be some aliquot part of 360, else their angular points cannot all meet in one point, neither can the surface be covered exactly. The angles of squares being right angles, or angles of 90°, it is obvious that four squares can completely cover any plane surface which is proportionable to their size, because  $90 \times 4 = 360$ . Six equilateral triangles can be joined without leaving any interstices, because the number of degrees contained in each of their angles is 60, and  $60 \times 6 = 360$ . Three hexagons can also be placed contiguous to each other, because 120, the number of degrees contained in each of their angles, multiplied by 3, produces 360: but no other figures could by any means be thus placed without leaving interstices; and it is useful to bear this in mind, because in mosaic work, inlaying, paving, and some kinds of ornamental painting, it is often requisite to cover a surface with some regular figure. We sometimes see octagons laid near each other in painted floors, &c. and there is always an empty space between them; but this empty space is a perfect square, because the number of degrees in each angle is 135, and as two angles only meet in one point, the sum of both,  $135 + 135$ , being equal to 270, there are evidently 90° required to make up the required number 360; and 90° are, as we have shown, contained in the angle of a square.

The honeycombs of a bee-hive afford a familiar illustration of the fact just explained, with respect to the figures which can cover a surface. Of the only three regular figures which can entirely fill up any given space, the bees have selected the hexagon; but here the question arises—Why were the little mathematicians led to choose the hexagon in preference to the square? The reason is cogent and philosophical: the object of the bees was not only to fit in their habitations

closely together, so that labour and wax might be saved, and that each little cell might be strengthened by the immediate juxtaposition of other cells, but also to render the interior of each cell as large and commodious as possible; because the young ones are lodged in these cells, and besides, the honey which is to supply the whole hive with food during the winter is stored away in them. Had the square or the equilateral triangle been chosen, the angles of the cell would in that case have certainly been farther from the centre, but the sides would have come nearer to it; for just in proportion to the number of sides is the length of the apothem. When a figure has but few sides, the apothem is comparatively short; and, other things being equal, it increases in length according as the sides are more numerous. The longer the apothem, the farther the sides recede from the centre; therefore it is clear that a figure of many sides circumscribes a larger space than a figure of equal perimeter, which has fewer sides. This is one of the reasons why a circular form is given to domestic utensils, such as ewers, bottles, casks, culinary vessels, &c. and also to water-pipes, and to the pipes used for conveying gas. A circle is merely a polygon of an infinite number of sides; on account of the infinite smallness of its sides it is free from all angular projections, and having more sides than any other polygon, it can, with a given perimeter, according to the principle just laid down, enclose the largest possible space. It follows from this, that if, from a given quantity of materials, a vessel is constructed having a circular form, that vessel will be found capable of receiving a larger volume of contents than another vessel wrought into any other form out of the same given quantity of materials would be able to contain. This principle is one of very extensive application, and is constantly acted upon in architecture and in many of the arts.

The capacity of a circle, as, for instance, a circular tube, is greatly increased by only a small addition to its diameter, because the increase is all round. The increase of capacity is in the ratio of the squares of the diameter: a tube 8 inches in diameter has four times the capacity of one which is 4 inches in diameter; one 16 inches in diameter has four times the capacity of one 8 inches in diameter; and so on.

MENSURATION OF PLANE FIGURES.

It is often requisite, for many practical purposes, to ascertain the exact size of a given figure. For this purpose certain lines of a determinate length, as inches, feet, yards, miles, &c. have been pitched upon as the units of measure or lineal units; and measuring a line consists in finding how often one or other of these units of measure is contained therein. Measuring a figure consists in finding the number of squares contained within its boundaries, the sides of each of those squares being equal to one of the lineal units above-mentioned; the number of squares, when found, is called the area or superficial content of the figure.

A rectangle is very easily measured, it only being requisite to ascertain its length and breadth, and then to multiply the one by the other.

If CE is a rectangle, and M the unit of measure, as, for example, a foot; and if the base CD contains M 4 times, and the side DE contains it 3 times, the number of squares described on M that are contained in CE is just  $= 4 \times 3 = 12$  square feet. For by laying off parts on CD, DE, equal to M, and drawing through the points of division lines parallel to the sides of the figure, it will evidently be divided into 3 rows of squares, each containing 4 squares; that is,  $3 \times 4 = 12$  squares or square feet.

If the side CD contained  $4\frac{1}{2}$  inches, and DE 3 inches, it would similarly be found that the number of square inches in the figure would be  $= 4\frac{1}{2} \times 3 =$

$\frac{1}{2} \times 3 = 1\frac{1}{2}$  square inches; or  $4\frac{1}{2} \times 3 = 13\frac{1}{2}$  square inches; and whatever is the length of the sides, the area is found always in the same manner.

The area of a square is at once known by multiplying one of the sides by itself; thus supposing one side of a square table to measure 4 feet, then 4 multiplied by 4 gives the whole number of square feet contained in the table—namely, 16.

It is demonstrated by Euclid, that parallelograms upon the same base and between the same parallels are equal to each other; from this it follows that the area of a rhombus and a rhomboid can be ascertained by the same easy process adopted for measuring rectangles—namely, by multiplying the length by the perpendicular height or breadth. The area of a triangle is also found in the same way, the base being multiplied by the perpendicular height; but only half the product denotes the content of the triangle, because a triangle is exactly the half of a parallelogram of the same base and altitude.

The area of any quadrilateral may be found by the same method: a diagonal being drawn from two of its opposite angles, it will be divided into two triangles, and by computing as above the area of each triangle, and then adding their areas together, their sum will indicate the whole extent of area comprised within the quadrilateral. The area of a trapezoid is generally found by multiplying half the sum of the two parallel sides by the perpendicular distance between them; the area of a trapezium may likewise be found in the same way. When it is desired to ascertain the area of an irregular polygon, diagonals must be drawn between the opposite angles; this will divide the figure into quadrilaterals or trapezoids, and triangles, and the area of each of these must be found separately, according to the above rules; all these areas added together will give the whole superficial content of the polygon.

The area of a regular polygon is found by adding all the sides together, and then multiplying the sum by the apothem; half the product will be equal to the area. The reason of this is, that every regular polygon may be divided into as many equal triangles as it has sides, and as the area of a triangle is equal to half the product produced by the multiplication of the base by the perpendicular, so the total amount of all the triangles forming a polygon may be found by multiplying the sides of the polygon, which are the bases of the respective triangles, by half the apothem; because the apothem, as before explained, is only a perpendicular drawn from the centre of the polygon to the middle of one of the sides, and is therefore equal to the perpendicular height of each triangle; half the product, as in the case of a single triangle, therefore, gives the required area.

The rule for finding the area of a polygon leads to that for finding the area of a circle; because, as before observed, a circle may, by approximation, be considered as a regular polygon with an infinite number of infinitely small sides. As the area of a polygon is obtained by the multiplication of its perimeter by its apothem, so it may naturally be inferred that the multiplication of the circumference of a circle by its radius will be the means of discovering the area of the circle. But here a difficulty arises; it is evident that the radius and circumference cannot be multiplied until the exact length of each be known: there is no difficulty of this kind in the measurement of polygons, because their sides, being straight lines, can easily be measured; the radius of a circle, being also a straight line, can be measured with equal facility; but how are we to ascertain the length of the circumference? This question has occupied the attention of philosophers from age to age, and was never solved to the entire satisfaction of any till about a century ago. Innumerable attempts have been made to discover what ratio a circumference bears to its diameter. Archimedes, one of the Greek geometers, who lived more than two thousand years ago, assigned the ratio to be as 7 to 22; nearer ratios have been

discovered since his time. A Dutch mathematician carried the ratio to 36 figures, and this was at the time considered so important a discovery, that it was engraved on his tombstone at Leyden. Others subsequently extended the ratio still further; and in a French work published about 1719 A. D., it was carried to no less than 128 figures. The ratio 31416 is sufficiently accurate for all common purposes. When very great accuracy is required, the ratio 314159 may be used instead of 31416. Sometimes the ratio 31415926536 is taken, but such a high degree of accuracy is seldom required. The general rule for finding the length of the circumference of a circle is to multiply the diameter by the ratio, and the product is the circumference; or to add the constant logarithm 0.4971509 to that of the diameter, and the sum is the logarithm of the circumference.

CONSTRUCTION OF SCALES—PROPORTION.

In practical geometry, scales of various kinds are used for the construction of figures. Scales are lines with divisions of various kinds marked upon them, according as they are to be used for measuring lines or angles. The name of *scales* is given to lines so divided, because the Latin word for ladder is *scala*, and the divisions are equidistant like the steps of a ladder. A line so divided is for the same reason said to be *graduated*, this word being derived from the Latin *gradus*, a step.

The *values* of the magnitudes of lines or angles are numbers representing the number of times that some unit of the same kind is contained in them.

The *unit of measure* for lines is some line of given length, as a foot, a yard, a mile, and so on.

The unit of measure for angles is, as we have already shown, the ninetieth part of a right angle.

The method of constructing a scale of equal parts is the following:—

Lay off a number of equal divisions, AB, BC, CD, &c., and AE, and divide AE into 10 equal parts. When

a large division, as AB, represents 10, each of the small divisions in AE will represent 1. When each of the large divisions represents 100, each of the small divisions in AE represents 10. Hence, on the latter supposition, the distance from C to n is 230; and on the former supposition, it is 23.

If the large divisions represent units, the small ones on AE represent tenths—that is, each of them is  $\frac{1}{10}$  or .1. On this supposition the distance Cn is 2.3.

To construct a plane diagonal scale.

1. A diagonal scale for two figures.

Draw five lines parallel to DE, and equidistant, and

lay off the equal divisions AE, AB, BC, CD, &c., and make EP, AQ, B1, C2, &c. perpendicular to DE. Find m the middle of AE, and draw the lines Qm, mP.

The mode of using this scale is evident from the last. If the large divisions denote tens, then from a to o is evidently 34.

2. A diagonal scale for three figures.

Draw ten lines parallel to DE, and equidistant. Lay off the equal parts AB, BC, CD, &c., and AE, and draw EP, AQ, B1, C2, ... &c. perpendicular to DE. Divide QP, AE, into 10 equal parts. Join the 1st, 2d, 3d, ... divisions on QP with the 2d, 3d, 4th, ... divisions on AE respectively.

If the divisions on AD each represent 100, each of those on QP will represent 10. Thus from 3 on AD to 8 on QP is 380; but by moving the points of the compasses down to the fourth line, and extending them from  $n$  to  $o$ , the number will be 384. For the distance of 8 on QP from Q is 80, and of  $r$  from A is 90; and hence that of  $o$  from the line AQ is 84.

When the divisions on AD denote tens, those on QP denote units; and from  $n$  to  $o$  would then represent 38 $\frac{1}{10}$ , or 38'4.

When the numbers representing the lengths of the sides of any figure would give lines of an inconvenient size taken from the scale, the numbers may be all multiplied or all divided by such a number as will adapt the lengths of the lines to the required dimensions of the figure.

Scales, by enabling us to ascertain the length of lines and magnitudes of figures, are very useful in the investigation of the doctrine of proportion. The import of the term proportion has already been sufficiently dwelt upon in arithmetic; and the reader has only to apply the ideas there developed to lines and to figures.

To prevent any misapprehension on the subject, it is well to understand clearly the distinction between the terms *equal* and *similar* figures. Equal figures are those which are precisely the same in every respect, being of the same size and of the same form. Similar figures are those which are precisely of the same form or shape, but of different sizes; the angles of two similar figures are equal, and the homologous sides—that is, the sides which lie in the same relative position in each figure—are proportional.

There is always a difficulty in the demonstration of the doctrine of proportion, on account of the frequent occurrence of incommensurable quantities—that is to say, quantities which have no common measure; the subject is, however, rendered clearer by the higher branches of mathematics.

The applications of the doctrine of proportion are very numerous and important, for it is the very foundation of many arithmetical, algebraical, and trigonometrical operations. It furnishes rules for taking plans in architecture and surveying; a map, whether of an estate or of a country, is merely a proportional representation on a small scale of the exact outline of a district. Sculpture and painting, usually numbered among the fine arts, are really wholly dependent upon the mathematical doctrine of proportion; a statue or bust, for instance, is either equal to some given figure, and is then familiarly termed 'large as life,' or else it is a similar figure, proportionally larger or smaller than the given figure, according as it is constructed on a larger or a smaller scale. In the same way landscape paintings are merely delineations of the prominent forms in natural scenery, all of which are represented in proportion on a smaller scale; and the value of the painting in a great measure depends on the mathematical exactness of these proportions.

ANALYSIS OF EUCLID'S ELEMENTS.

It is one of the most remarkable facts in the history of science, that while the great majority of ancient scientific treatises have been altogether cast aside, and their place supplied by more recent productions, destined in their turn to be as entirely superseded by others of still more recent date, yet that one book has weathered every ebb and flow of popular opinion, and still holds as high, if not a higher, place in the public estimation, as when first given to the world. This work was written more than 2000 years ago; and it is surely scarcely necessary to add, that Euclid was the author, or perhaps rather the compiler, of this extraordinary production. There are thirteen books extant written by Euclid, and hence called 'Euclid's Elements.' The fourteenth and fifteenth books are supposed to have been added by Hyacles of Alexandria, about 170 A.D. The method of reasoning pursued throughout these 'Ele-

ments,' and adopted by all mathematicians, is the following:—In the first place, certain definitions, postulates, and axioms, are laid down, which form the entire basis of all mathematical science. Perhaps it might be advisable to make a few observations on the exact meaning of these terms before we proceed farther.

By a *definition* is merely meant an explanation or a description of the characteristic properties of the object defined; the assertion, for instance, that 'an isosceles triangle is that which has only two sides equal,' is a definition, because it conveys to an unlearned person an idea of the meaning of the term *isosceles*.

A *postulate* is something that is allowed to be done, or to be *imagined* to be done. The postulates given by Euclid are the following:—

1. A line may be drawn from any one point to any other point.
2. A line may be produced (that is, continued or lengthened) at pleasure to any length.
3. A circle may be described about any centre, and at any distance, or with any radius. It will be evident, from a careful examination of these postulates, that when necessary to prove any process of reasoning, it is permitted to draw a line to the moon, and another from the moon to a star, or to any point in the heavens; and although it is of course impossible really to draw such lines, yet by these postulates we are permitted to *imagine* them to be so drawn. It is also evident, that by these postulates we are permitted the use of two instruments in mathematical reasoning—namely, the ruler and the compasses.

Mascheroni, an Italian mathematician, endeavouring to render the narrow basis upon which geometry is upreared still more narrow, suggested a method of performing all mathematical problems by the aid of compasses alone, dispensing altogether with straight lines and the ruler: an account of this plan may be seen in a celebrated work published by Mascheroni about A. D. 1797, entitled '*Geometria del Compasso*' ('Geometry of the Compasses').

An *axiom* is a statement of some simple fact which is self-evident, or requires no proof; thus, the 9th axiom is an assertion that the whole is greater than its part. It is impossible to doubt a statement like this; even a child is prepared to admit its truth; for who is not aware that a whole mass of stone, for instance, is greater than any fragment that may be broken off it? and every day's observation is equally confirmatory of all the other axioms, which, as propounded by Euclid in the first book, are the following:—

1. Things which are equal to the same thing, are equal to one another.
2. If equals be added to equals, the wholes are equal.
3. If equals be taken from equals, the remainders are equal.
4. If equals be added to unequals, the wholes are unequal.
5. If equals be taken from unequals, the remainders are unequal.
6. Things which are double of the same, are equal to one another.
7. Things which are halves of the same, are equal to one another.
8. Magnitudes which coincide with one another—that is, which exactly fill the same space—are equal to one another.
9. The whole is greater than its part.
10. All right angles are equal to one another.
11. Two straight lines cannot be drawn through the same point, parallel to the same straight line, without coinciding with one another.
12. It is possible for another figure to exist, equal in every respect to any given figure.

Geometrical facts and suppositions are, by Euclid and all other mathematicians, couched in a form of expression called a *proposition*. There are three kinds of propositions—*theorems*, *problems*, and *lemmas*. A *theorem* is a statement of some truth or class of truths; but as,

with the single exception of the axioms, no bare assertion or statement is admitted into geometry unless fully corroborated by proofs, a theorem requires to be demonstrated. There is no way of proving the truth of a theorem, except by reference to some truth or truths already established by previous theorems; which again must have been demonstrated by some preceding theorems; and thus we are led back from theorem to theorem, until we arrive at the foundation upon which they are all found to rest—namely, the definitions and axioms.

A *problem* either proposes something to be effected, as the construction of a figure, or it is a question which ought to be solved; in either case it requires something to be done, and therefore depends entirely upon the postulates for its solution. After the *solution* has been stated, its sufficiency for performing all the required conditions still remains to be proved.

A *lemma* is a theorem which properly belongs to some other part of geometry, but which, from the close connection which subsists between all the branches of mathematical science, is often fitly introduced to explain some difficulty which would otherwise arise in the demonstration of the succeeding theorems or problems. As lemmas rather disturb the continuous order of a subject, they are never used by good mathematicians except when absolutely requisite.

Having now explained the meaning of the terms used in geometrical reasoning, the following observations on the nature of that reasoning, and the method pursued by Euclid and others, will be readily understood:—A proposition is first stated in general terms: take, for instance, the 20th proposition—'Any two sides of a triangle are together greater than the third side.' This is but bare assertion: to advance a step farther, Euclid places the figure referred to—namely, a triangle—before the student, and tells him that, in the annexed triangle—namely, ABC—any two sides of it together are greater than the third side; that is to say, the sides BA, AC are together greater than the one side BC; the sides AB, BC are greater than AC; and BC, CA are greater than AB. This is certainly calling off the attention from a mere general observation, and confining it for a time to the examination of one individual case; it is also demanding the assent of the perceptive faculties; for the moment that the eye lights upon the triangle ABC, the mind is immediately ready to acknowledge that two of its sides are together greater than only one of its sides: yet the matter cannot rest here. Euclid knew, as well as any of our modern philosophers, that there are two primary principles in the human intellect: the eye sees and conveys its impressions directly to the perceptive or observing faculties; but information thus acquired ought to be immediately brought under cognisance of those faculties which enable us to trace the cause as well as the effect, and to compare the relation of things. Euclid therefore subjected every proposition he advanced to a double kind of proof, by addressing both the sets of faculties which compose the human intellect: perhaps this may alone be sufficient to account for the fact, that his work has from age to age been used as the text-book of elementary geometry, while other works, because less truly philosophical, have engrossed public attention for a moment, and have then sunk into oblivion.

A brief analysis of the several books composing what is called 'Euclid's Elements,' may not be unacceptable to the unlearned reader. The first three propositions in Book I. are problems, and show the several methods of describing an equilateral triangle, of drawing a straight line equal to a given straight line from a given point, and of cutting off from the greater of two given straight lines a part equal to the less. The 4th proposition is the first theorem which occurs in Euclid, and requires to be examined a little in detail, because, in connection with the 8th proposition, it forms the foundation of all that is advanced respecting the compar-

son of triangles. This important theorem, as stated by Euclid, is as follows:—

If two triangles have two sides of the one equal to two sides of the other, each to each, and have likewise the angles contained by those sides equal to one another, their bases, or third sides, shall be equal, and the two triangles shall be equal, and their other angles shall be equal, each to each—namely, those to which the equal sides are opposite. Or if two sides and the contained angle of one triangle be respectively equal to those of another, the triangles are equal in every respect.

Let ABC, DEF be two triangles, which have the two sides AB, AC equal to the two sides DE, DF, each to each—namely, AB to DE, and AC to DF, and the angle BAC equal to the angle EDF; the base BC shall be equal to the base EF, and the triangle ABC to the triangle DEF; and the other angles,

to which the equal sides are opposite, shall be equal, each to each; namely, the angle ABC to the angle DEF, and the angle ACB to DFE. The method adopted for demonstrating this theorem, as well as that contained in the 8th proposition, is a peculiar species of demonstration which has received the name of *superposition*: it is, in reality, the same method pursued by tailors and dressmakers when they wish to satisfy themselves as to whether a piece of cloth has been cut correctly from a given pattern; they place their original pattern and the piece of cloth or silk together, the one behind the other, and carefully observe whether the edges of one project beyond those of the other; but if they both coincide in every point, the tailor knows that his cloth has been correctly cut according to the pattern. In the same way Euclid requires the triangle ABC to be applied to, or placed exactly over, the triangle DEF, so that the point A may be on D, and the straight line AB upon DE, the point B shall coincide with the point E, because AB is equal to DE; and AB coinciding with DE, AC shall coincide with DF, because the angle BAC is equal to the angle EDF; wherefore, also, the point C shall coincide with the point F, because AC is equal to DF; but the point B coincides with the point E, wherefore the base BC shall coincide with the base EF, and shall be equal to it. Therefore, also, the whole triangle ABC shall coincide with the whole triangle DEF, and be equal to it; and the remaining angles of the one shall coincide with the remaining angles of the other, and be equal to them—namely, the angle ABC to the angle DEF, and the angle ACB to the angle DFE. The postulates do not permit one triangle to be cut out and placed over the other, therefore Euclid only *imagines* what would be the result supposing this were to be done. This theorem depends entirely upon the 8th axiom, being, in point of fact, merely what a logician would call the converse of it; for in the 8th axiom it is stated, that magnitudes which coincide with one another—that is, which exactly fill the same space—are equal to one another; and in this theorem, in order to prove them equal, it is proved that they coincide.

The demonstration of the 6th proposition is the first instance in Euclid of a species of reasoning termed by logicians *indirect*, or a *reductio ad absurdum*, and which consists in proving a theorem to be true by showing that an absurdity would follow from supposing it false. The theorem here advanced is, that if two angles of a triangle be equal to one another, the sides which subtend, or are opposite to, those angles, shall also be equal to one another, and it is demonstrated by the following indirect mode of reasoning:—Let ABC be a triangle, having the angle ABC equal to the angle ACB, the side AB is also equal to the side AC. For if AB be not equal to AC, one of them is greater than the other. Let AB be the greater, and from it cut off DB equal to AC, the less, and join DC, therefore, because in the triangles

## GEOMETRY.

DBC, ACB, DB is equal to AC, and BC common to both; the two sides DB, BC are equal to the two AC, CB, each to each; but the angle DBC is also equal to the angle ACB; therefore the base DC of the one is equal to the base AB of the other, and the triangle DBC is equal to the triangle ACB, the less to the greater, which is absurd. Therefore AB is not unequal to AC—that is, it is equal to it.

The corollary or inference drawn from this is, that all triangles having equal angles have also equal sides.

The 7th proposition affords another specimen of that kind of indirect demonstration, which logicians call a *dilemma*. It is stated in the proposition that, upon the same base, and on the same side of it, there cannot be two triangles that have their sides which are terminated in one extremity of the base equal to one another, and likewise those which are terminated in the other extremity equal to one another. This is proved by examining separately every possible position in which two equal triangles can be imagined to be placed so as to have but one base: it is evident that if they could be so placed, the vertex of one triangle must be either without, within, or on one side of the other triangle; each of these suppositions is examined separately, and each proved to be impossible; the reader is thus brought into a dilemma, having no alternative but to admit the truth stated in the theorem. There are many instances in which this species of demonstration is used by Euclid.

The 8th proposition refers to equal triangles.

The 9th, 10th, 11th, and 12th propositions are useful practical problems, showing how to bisect (that is, divide in two) an angle and a straight line; also how to draw a straight line at right angles to a given straight line, from a given point in that given line, as well as from a point without or beyond that given line.

The 16th, 17th, 18th, and 19th propositions refer to the angles of triangles. The next proposition most worthy of examination is the 26th, which investigates the same subject as the 4th and the 8th—namely, the conditions of the equality of triangles. The 4th proposition has already been fully explained. In the 8th it is proved that if two triangles have two sides of the one equal to two sides of the other, each to each, and have likewise their bases equal, the angle which is contained by the two sides of the one shall be equal to the angle contained by the two sides of the other; or if the three sides of one triangle be respectively equal to those of another, the triangles are equal in every respect. Thus let ABC, DEF be two triangles having the two sides AB, AC equal to the two sides DE, DF, each to each—namely, AB to DE, and AC to DF; and also the base BC equal to the base EF; the angle BAC is equal to the angle EDF, and the angles at B and C of the triangle ABC are respectively equal to those at E and F of the triangle DEF. The 26th proposition gives still further information on this useful subject. It shows that if two triangles have two angles of the one equal to two angles of the other, each to each, and one side equal to one side—namely, either the sides adjacent to the equal angles, or the sides opposite to the equal angles in each, then shall the other sides be equal, each to each, and also the third angle of the one to the third angle of the other; or if two angles and a side in one triangle be respectively equal to two angles and a corresponding side in another triangle, the two triangles shall be equal in every respect. Thus let ABC, DEF be two triangles which have the angles ABC, BCA respectively equal to DEF, EFD—namely, ABC to DEF, and BCA to EFD; also one side equal to one side; and first, let those sides be equal

which are adjacent to the angles that are equal in the two triangles—namely, BC to EF; the other sides shall be equal each to each—namely, AB to DE, and AC to DF; and the third angle BAC to the third angle EDF. This little group of theorems is found very useful in the arts, for it is often requisite to have some rule by which to be able at once to determine whether two given triangles are exactly equal to each other; and if such rules were firmly engraven in the mind of every mechanic, there is no doubt but that there would be far less expenditure of time, labour, and money.

In the 27th proposition, the investigation of the properties of parallel lines is commenced, and this subject is continued through the 28th, 29th, 30th, and 31st propositions, until suddenly broken off by the introduction of one of the most remarkable propositions in the whole book—namely, the 32d, in which it is shown that the three interior angles of a triangle are together equal to two right angles. This important fact has already been examined, and therefore we have only to add that it was discovered by Pythagoras, a philosopher of Samos, about 500 a. c. The doctrine of parallel lines must not be dismissed hastily, for, with the exception perhaps of proportion, no other part of elementary geometry has created so much perplexity and discussion. The first two theorems relating to parallel lines are very simple and easily demonstrated; for the 27th theorem only affirms, that if a straight line falling upon two other straight lines makes the alternate angles equal to one another, these two straight lines shall be parallel. The 28th theorem is equally easy of demonstration, as it merely assumes that if a straight line falling upon two other straight lines makes the exterior angle equal to the interior and opposite angle upon the same side of the line, or makes the interior angles upon the same side together equal to two right angles, the two straight lines shall be parallel to one another. To make this more clear, it may be as well to subjoin an example.

Let the straight line EF, which falls upon the two straight lines AB, CD, make the exterior angle EGB equal to the interior and opposite angle GHD upon the same side; or make the interior angles on the same side, BGH, GHD, together equal to two right angles; AB is parallel to CD. But the 29th proposition assumes the converse of this—namely, if a straight line fall upon two parallel straight lines, it makes the alternate angles equal to one another; and the exterior angle equal to the interior and opposite upon the same side; and likewise the two interior angles upon the same side together equal to two right angles. Now the assertion contained in this theorem is both easy of comprehension and evident to the senses; the difficulty lies in subjecting it to that rigorous demonstration to which all theorems must be brought before they can be received as mathematical truths. Euclid has endeavoured to prove it by means of a *reductio ad absurdum*, but this species of demonstration is for many reasons never adopted by good mathematicians, when it is possible to prove the truth of a statement by any other process of reasoning. Almost every succeeding mathematician has devised some particular method of his own to elucidate the doctrine of parallel lines, but no one has ever yet fully succeeded in effecting the required demonstration.

The 30th proposition shows that straight lines which are parallel to the same straight line are parallel to one another. The following demonstration of this fact is founded upon the truths previously advanced in the 29th and 27th propositions:—

Let the two lines AB, CD be parallel to EF; then AB and CD are parallel to one another. For because GHK cuts the parallel straight lines AB, EF, the angle AGH is equal to the angle GHF. Again, because the straight line GK cuts the parallel straight lines EF, CD,

the angle GHF is equal to the angle GKD; and it was shown that the angle AGK is equal to the angle GHF; therefore, also, AGK is equal to GKD, and they are alternate angles; therefore AB is parallel to CD.

The 33d proposition resumes the chain of demonstration, which was suddenly interrupted by the insertion of the famous 32d proposition, and continues the investigation of the properties of parallel lines. This subject naturally leads to the examination of parallelograms; and indeed it may be said that almost all the succeeding propositions in the first book are devoted to the investigation of parallelograms, and the relation subsisting between the properties of parallelograms and those of triangles. In proposition 35, for instance, it is alleged that parallelograms upon the same base and between the same parallels, are equal to each other; in proposition 37, the same fact is affirmed with respect to triangles—namely, that triangles upon the same base and between the same parallels are equal. Propositions 36 and 38 are the converse of the preceding. The most celebrated, however, of the succeeding theorems, and the most striking, perhaps, in the whole range of geometrical science, is the 47th proposition. We subjoin the theorem and the example given, and refer those who are curious as to the method of demonstration to Euclid himself. In any right-angled triangle, the square which is described upon the sides subtending the right angle, is equal to the squares described upon the sides which contain the right angle. Let ABC be a right-angled triangle, having the right angle BAC; the square, described upon the side BC, is equal to the squares described upon BA, AC; that is, the square BE is equal to the two squares BG and CH. Pythagoras had also the honour of discovering this important truth. It is related, that immediately upon the discovery, he was so transported with joy at the value of the truth, and with gratitude at being permitted to reveal it to the human race, that he sacrificed a whole hecatomb—that is to say, a hundred oxen, as a testimony of his thankfulness. This story is entirely fabulous; yet something may be gained even from a fable; and from this fictitious narration we learn, that the truth now unfolded in the 47th proposition was held in the highest estimation, not only by the discoverer, but by the ancients who invented the fable and who transmitted it to posterity.

Having now examined Euclid's method of reasoning, and the various forms of logical arguments employed by him, and adopted by others in demonstrations, it now only remains to glance rapidly at the contents of the other books.

In the second book, the properties of rectangles and squares, formed under given lines, constitute the principal subject of investigation. All the demonstrations in this book are very simple; many of them consist chiefly in proving that the figure drawn is really composed of the rectangles alluded to in the proposition; and most of the demonstrations are founded upon the self-evident principle, that the whole is equal to all its parts taken together. The three first propositions show the theory of common mathematical multiplication, and also that of the mensuration of rectangles in practical geometry, already explained. The 4th may be called a geometrical demonstration of the rule laid down for extracting the square root to two terms in arithmetic and algebra. The 5th, 6th, 7th, and 8th propositions show the principles upon which some useful operations in algebra are conducted; all the remaining propositions of this book are of great value in trigonometry.

The third book is devoted entirely to the investigation of the circle, and of various lines considered with reference to the circle, and drawn within or without its circumference. The properties of tangents and of

tangent circles are fully considered; and also the relation between angles which are made at the circumference and those made at the centre. This book is of great use in various mechanical arts; it is also the foundation of practical geometry, the circle being very frequently used in the construction of complicated figures.

The fourth book may be considered as a continuation of the third, as it treats of such figures as cannot be easily drawn without the circle. It explains the methods of describing regular polygons in and about circles; and conversely, to describe circles in and about regular polygons.

The fifth and sixth books may be considered together, being both devoted to the same subject—namely, the doctrine of proportion. The fifth book is introductory to the sixth, for it lays down abstract theorems relative to proportion; and the sixth book shows the application of these theorems to geometry. Every branch of mathematical science is more or less dependent upon the demonstrations contained in these two books.

The seventh, eighth, ninth, and tenth books are never put into the hands of students, being of very little use in any part of mathematics. The doctrine of proportion is more or less dwelt upon in all of these four books; and they also treat of the greatest common measure of any two numbers, of square and cube numbers, and of incommensurable quantities. The main, if not the only, object of Euclid, in writing these four books, seems to have been to settle the intricate question of incommensurables.

The remaining books of Euclid are entirely devoted to the examination of solids, and to the investigation of their properties and relations.

SOLID GEOMETRY.

It has been already observed, that all bodies having length, breadth, and thickness, such as wood, timber, &c. are called solids; and that the investigation of the properties and relations of the various figures assumed by such bodies, is the object of solid geometry.

The boundaries of solids are surfaces. Those solids which are bounded by plane surfaces are called *polyhedrons*, from the Greek words *polus*, many, and *edra*, a seat. The planes which contain a polyhedron are called its *sides* or *faces*; the lines bounding its sides are termed its *edges*; and the inclination of any two of the planes is called a *dihedral* angle.

The meaning of parallel lines having been already explained, it is only necessary to say that the word parallel has the same signification when applied to planes as when applied to lines. *Parallel planes*, like parallel lines, would never meet, even if lengthened to any extent. The ceiling and the floor of a room are parallel planes.

A *solid angle* is formed by three or more plane angles meeting in the same point. The corner of a box, for instance, is a solid angle formed by the junction of three angles—namely, the plane angle terminating one side of the upper or under surface of the box, and the two plane angles belonging to its two sides.

The generic name of *prism* is given to all polyhedrons contained between two opposite, parallel, and equal polygons, connected together by parallelograms. The common bricks used in masonry are familiar examples of one species of prism; the little optical instrument used for showing the colours of rays of light, is another kind of prism—it is a glass, bounded by two equal and parallel triangular ends, and three equal and similar sides. The two ends of prisms are generally called the *terminating planes*, and one of them is called the *base*. The edges of the sides are called the *lateral edges*, and those of the terminating planes are called the *terminating edges*. Prisms may be right or oblique, regular or irregular. In *right* prisms, the lateral edges are perpendicular to the base; in *oblique* prisms the sides are in an oblique position with respect to the base. A right prism, having regular polygons for its

terminating planes, is said to be *regular*; an *irregular* prism is one in which the ends are irregular polygons. The line joining the centre of the terminating planes of a regular prism is called the *prismatic axis*, and the *altitude* or *height* of the prism is equal to the length of this line.

The parallelograms which form the sides of prisms are always equal in number to the sides of the base, and prisms are classed accordingly. The prisms which have a triangular base are called *triangular* prisms; those which have a quadrangular base are called *quadrilateral* prisms. *Hexagonal* prisms are those having a hexagon for their base; and *polygonal* prisms are those of which the base is a polygon. The parallelepiped and the cube are two quadrangular prisms, which, being of great importance in the arts, require special attention. The *parallelepiped* is bounded by six four-sided figures, of which every opposite two are parallel. It is called *rectangular* when its base is a rectangle; and when these six planes are all rectangles placed perpendicularly to each other, it is said to be *right*, and *oblique* when the planes are inclined to each other. We can scarcely look around us without seeing rectangular parallelepipeds. Beams of timber, hewn stones, the box of a gardener's wheelbarrow, the bodies of carts, are almost invariably rectangular parallelepipeds; and this form is generally given to houses and to rooms. It is one of the propositions of the 11th book of Euclid, that if a solid be contained by six planes, two and two of which are parallel, the opposite planes are similar and equal parallelograms; thus let the solid CDGH (which is a parallelepiped) be contained by the parallel planes AC, GF; BG, CE; FB, AE; its opposite planes are similar and equal parallelograms.

Parallelepipeds, when cut by a plane passing through the diagonals of two of the opposite planes, are formed into two equal triangular prisms.

Let AB be a solid parallelepiped, and DE, CF the diagonals of the opposite parallelograms AH, GB—namely, those which are drawn betwixt the equal angles in each; and because CD, FE are each of them parallel to GA, though not in the same plane with it, CD, FE are parallel; wherefore the diagonals CF, DE are in the plane in which the parallels are, and are themselves parallel; and the plane CDEF shall cut the solid AB into two equal parts.

Because the triangle CGF is equal to the triangle CBF, and the triangle DAE to DHE; and that the parallelogram CA is equal and similar to the opposite one BE; and the parallelogram GE to CH; therefore the planes which contain the prisms CAE, CBE are equal and similar, each to each; and they are also equally inclined to one another, because the planes AC, EB are parallel, as also AF and BD, and they are cut by the plane CE; therefore the prism CAE is equal to the prism CBE, and the solid AB is cut into two equal prisms by the plane CDEF.

*Def.*—The *insisting* straight lines of a parallelepiped, mentioned in the following propositions, are the sides of the parallelograms betwixt the base and the plane parallel to it.

Parallelepipeds are equal when they are upon equal bases and of the same altitude. This fact is very evident, and is constantly acted upon when the solids are right; for instance, in making book-shelves, each shelf is made equal to the others—that is, it is made equally long and equally broad, and has the same altitude or thickness. Solid parallelepipeds which have the same altitude, are to one another as their bases: thus let AB, CD be solid parallelepipeds of the same altitude; they are to one another as their bases—that

is, as the base AE to the base CF, so is the solid AB to the solid CD.

Whatever can be proved respecting the properties of parallelepipeds, is equally true with respect to those of cubes, because a cube is merely a parallelepiped with square sides. The dice used by gamblers are cubes; and tables, footstools, and rooms often receive a cubic form. Just as the unit of measure for plane surfaces is a square, so the *unit of measure for solids* is a cube, and the length of each side of the cube is an inch, a foot, a yard, or any other lineal unit which may be fixed. To measure the solidity of a solid is to ascertain how many cubic inches, or cubic feet, &c. are contained therein. The solidity of a parallelepiped is found by multiplying the length by the breadth, and the product by the height; the result gives the number of cubes contained within the figure.

Let  $l$ ,  $t$ , and  $h$ , be the length, breadth, or thickness, and the height, and  $v$  the volume or solid content; then  $v = lth$ .

Let AF be a right rectangular parallelepiped. Let its length AB be 4 lineal units, as 4 inches, its thickness BC 2 inches, and its height AD 3 inches. The solid can evidently be divided into three equal portions by planes through G and H, parallel to the base AC; and into four equal portions by means of planes through K, L, M, parallel to the side BF; and into two equal portions by a plane through I, parallel to BD. Each of the small cubes into which the solid is now divided, is a cubic inch; the number of cubic inches in the lowest portion HC is  $4 \times 2$ , or 8, and in the second and uppermost portion there are as many; and in them all, therefore, there are  $4 \times 2 \times 3$ , or 24—that is, to find the cubic contents of the solid, find the continued product of the length, breadth, and height.

The solidity of a cube is found by multiplying the side by itself, and that product again by itself; or, literally, by raising the side to the third power.

Let  $e$  = an edge of a cube; then  $v = e^3$ .

The reason of the rule is evident, since a cube is just a A parallelepiped, whose length, breadth, and height are equal.

The solidity of all prisms, or of any parallelepiped, may be found by multiplying the area of the base by the height.

Let  $b$  denote the base, and  $h$  the height; then  $v = bh$ .

A pyramid is an angular solid, which has a polygon for its base, and triangles for its sides or faces; these sides all meet in one point, and form a solid angle, which is called the *vertex* of the pyramid. Pyramids, like prisms, may be either regular or irregular. When the base of a pyramid is regular, the line joining its vertex or summit is called its *axis*, and when the axis is perpendicular to the base, it is then a *regular* pyramid. They are also said to be triangular, quadrilateral, polygonal, &c. according as the base is a triangle, a quadrilateral, a polygon, &c. The Pyramids of Egypt are quadrilateral, having square bases and four similar and

equal triangular sides. An obelisk is also a pyramid, and has a square base and triangular sides; but the height is very great in proportion to the extent of the base. The solidity of a pyramid is found by multiplying the area of the base by the perpendicular height, and one-third of the product is the answer:  $v = \frac{1}{3} bh$ .

*Example.*—Find the solidity of a rectangular pyramid, the length and breadth of its base being 6 and 4 feet, and its altitude 20 feet.

$$v = \frac{1}{3} bh = \frac{1}{3} \times 6 \times 4 \times 20 = 160 \text{ cubic feet.}$$

By a regular solid is meant a solid bounded by regular plane figures, and its solid angles equal; that is to say, a solid in which all the sides are equiangular and equilateral. It has been proved that there can be only five regular solids; these are often called Platonic bodies, because Plato was the first who investigated their properties. The names of these five regular solids are the following; and it will be observed that these names are formed by prefixing the Greek numeral indicating the number of sides to the termination *hedron*, from *edra* (Greek), a seat; that is, a side:—

The *tetrahedron* is a regular triangular pyramid, whose sides are equilateral triangles. The *hexahedron* is a cube. The *octahedron* is contained by eight equilateral triangles. The *dodecahedron* is contained by twelve regular pentagons. The *icosahedron* is contained by twenty equilateral triangles. Each side of a regular solid, except the tetrahedron, has an opposite face parallel to it, and the edges of these faces are also respectively parallel.

A cylinder differs from a prism in having a circular instead of a rectilinear base; it is contained between two equal and parallel circles and a convex surface. The line joining the centres of the two circles is called the *axis*. When the axis is perpendicular to the plane of the bases, the cylinder is said to be *right*. Steam-boilers, the shafts of circular pillars, the stone of a common garden roller, the barrel of a gun, and many other familiar objects, are cylinders. Combinations of cylinders are also very frequently used in the arts; telescopes and opera-glasses, for instance, are merely cylinders fitted one within the other, and of which circular lenses form the base. The solidity of a cylinder is found in the same way as that of a prism—namely, by multiplying the area of the base by the perpendicular height. This rule is founded upon the theorem that a cylinder and a parallelepiped, having equal bases and altitudes, are equal to one another. A cone, like a cylinder, has a circular base, but it terminates in a point like a pyramid; sugar-loaves are made in the form of cones. The annexed figure is a cone.

AB is the base, V is the vertex, and the straight line VD joining the vertex and the centre of the base is called the *axis*. A frustum of a solid is a portion contained between the base and a plane parallel to it; thus the portion EGAB is a frustum of the cone. When the axis of a cone is perpendicular to its base, it is called a *right* cone. Other cones are said to be *oblique*. A right cone may be described by the revolution of a right-angled triangle about one of the sides of the right angle. It is proved that if a cone and a cylinder have the same base and the same altitude, the cone is equal to the third part of the cylinder. From this fact results the method usually adopted for ascertaining the solidity

of a cone. The area of the base is multiplied by the altitude, which, as before shown, is the rule for finding the solidity of a cylinder; one-third of the result, therefore, gives the solidity of the cone.

**SPHERICAL GEOMETRY.**

A *sphere* or *globe* is a solid having one continued curved surface, and which is conceived to be generated by the revolution of a semicircle about its diameter: balloons and cricket-balls are spheres.

Spherical geometry consists in the investigation of the properties of spheres.

Every point on the surface of a sphere is equally distant from a point in the middle of the sphere called its *centre*; any line drawn from the centre to the circumference is called a *radius*, and any line drawn through the centre, and terminated at both extremities by the circumference, is termed a *diameter*. When the diameter is perpendicular to the plane of a circle of the sphere, it is termed an *axis*, and the extremities of the axis are called the *poles*. Circles of the sphere, whose planes pass through the centre, dividing the sphere into two equal parts, are called *great* circles, and all others are *small* circles. By the distance of two points on the surface of a sphere, is meant an arc of a great circle intercepted between them.

A *spherical angle* is that formed on the surface of the sphere by arcs of two great circles meeting at the angular point, and is measured by the inclination of the planes of the circles.

A *spherical triangle* is a figure formed on the surface of the sphere by arcs of three great circles, called its *sides*, each of which is less than a semicircle.

A *quadrantal triangle* is that of which one of the sides is a quadrant.

A *lunary surface* is a part of the surface of the sphere, contained by the halves of two great circles.

A *segment* of a sphere is a part cut off by a plane.

There are several methods of finding the contents or solidity of a sphere; perhaps the most simple and the most easy to be remembered is the following: Find, by the rules previously given, the solidity of the circumscribing cylinder, as EABF, which is a cylinder equal in diameter and height to the diameter of the sphere; two-thirds of it will be the volume of the sphere, because a sphere is proved to be equal to two-thirds of its circumscribing cylinder.

The exterior extent of surface, or convex superficies of a sphere, may be ascertained by multiplying the diameter of the sphere by its circumference. Thus in a globe of 20 inches diameter, and 62'832 circumference, the convex superficies is 1256'64 inches, because 62'832  $\times$  20 = 1256'64. Also, the surface of any zone of the sphere, as *mm'm'*, is exactly equal to the surface of the corresponding zone of the cylinder *mm'm'*.

Spherical geometry is of great importance in several of the arts and physical sciences, and more especially in astronomy and navigation.

**TRIGONOMETRY—LAND-SURVEYING.**

Trigonometry signifies literally the art of measuring triangles, but with the progress of science the meaning of the word has been much extended. Trigonometry is divided into plane and spherical, according as it is directed to the investigation of plane or of spherical triangles.

A fixed relation subsists between certain lines drawn in and immediately round a circle; and it is upon this relation that trigonometry is founded. Most of these lines, such as tangents, secants, arcs, chords, &c. have already been mentioned; it only remains to add, that the sine of an arc is a straight line, drawn from one extremity of the arc perpendicular to the radius passing

## GEOMETRY.

through the other extremity, or it is in fact the half of the chord of double the arc. The sine, tangent, and secant of the complement of an arc, are called cosine, cotangent, and cosecant of that arc. This will be better understood by carefully examining the annexed figure, which is a representation of the various trigonometrical lines.

BC is the complement of the arc AB; BMD is the supplement of AB; angle BOC is the complement of AOB, and BOD is the supplement of AOB; BE is the sine of AB; AF is the tangent of AB; OF is the secant of AB; so BG is the sine of BC, or the cosine of AB; CH is the tangent of BC, or the cotangent of AB; and OH is the secant of BC, or the cosecant of AB.

The following rules for computation are useful in right-angled trigonometry; that is, in computing the sides and angles of right-angled triangles.

I. When two sides are given, to find an angle.

Make a given side radius, then the side made radius is to the other given side as radius to the trigonometrical name of the latter side.

II. When one of the three sides and an angle are given, to find a side.

Make any side radius, then the trigonometrical name of the given side is to that of the required side as the given side to the required side.

Although in this case any side may be made radius, it is preferable to make one of the sides concerned radius; that is, either the given or the required side, as this introduces the radius as a term of the proportion, and its logarithm being 10, it simplifies the calculation.

III. When the two sides are given, to find the hypotenuse.

The sum of the squares of the two given sides is equal to the square of the hypotenuse.

IV. When the hypotenuse and a side are given, to find the other side.

The difference between the squares of the hypotenuse and the given side, is equal to the square of the required side. Or, the product of the sum and difference of the hypotenuse and a side, is equal to the square of the other side.

When the square of a side is known, its square root gives the value of the side.

The first two rules are sufficient for the solution of all the problems in right-angled trigonometry; but the last two may sometimes be conveniently employed.

Trigonometry is one of the most useful departments in mathematical science. Its applications to practical purposes are very extensive, and it is of great importance in navigation, engineering, and, as we shall immediately see, in land-surveying.

Land-surveying is the method of measuring and computing the area of any small portion of the earth's surface, as a field, a farm, an estate, or district of moderate extent. There are three distinct operations in the art of land-surveying, all of which require the surveyor to possess a competent knowledge of arithmetic, algebra, and geometry. In the *first* place, the several lines and angles must be measured; *secondly*, they must be protracted or laid down on paper, so as to form a plan or map of the district; and, *thirdly*, the whole area of the district must be computed by means of the foregoing operations. In performing the first operation, the most useful instrument is a chain called *Gunter's chain*, from the name of the inventor, the Rev. Edmund Gunter, who lived about two hundred years ago. It is 22 yards or 66 feet long, and is composed of 100 equal links, the length of each being 7.92 inches. At every tenth link is a mark made of brass. An acre consists of 10 square chains, or 100,000 square links. There are 80 chains in a mile, and 640 acres in a square mile.

Iron pins, about two feet long, called *arrows*, with

red handles, or pieces of red cloth, attached to them, are used for sticking in the ground at the end of each chain length when measuring in the field. Ten of them are commonly used.

In measuring land with the chain, two persons are required, one at each end of the chain; the one who walks first is, for the sake of distinction, called the leader, and the other the follower. Lines measured perpendicularly to chain lines, to the angular points, and other points of the boundary of a field, such as to crooked hedges, brooks, &c. are called *offsets*. The cross-staff is used in measuring offsets: it consists of two bars of brass placed at right angles, with sights at their extremities, perpendicular to the plane of the bars. There are narrow slits at A and C, to which the eye is

applied, and wider openings at B and D, with a fine wire fixed vertically in the middle of them. The cross is supported on a staff E, about 4 1/2 feet high, which at the lower end is pointed and shod with brass, so that it can easily be stuck in the ground. The sights are placed on the top of the staff, and fixed to any position by a screw F.

A simple cross staff may be made by cutting

two grooves with a saw along the diagonals of a square board, to be fixed on the top of the staff. It can easily be ascertained if the sights are at right angles, by directing one pair of them, as AB, to one object, and observing to what object the other pair, CD, are then directed; then by turning the sights till the second object is seen through the first pair of sights AB, if the first object is then visible through the second pair of sights, and is exactly in apparent coincidence with the wire, the sights are at right angles; if not, they must be adjusted.

An instrument not less important in surveying is the theodolite. This useful instrument, fixed on the top of a tripod, consists of two graduated circles perpendicular to each other; one of which is fixed in a horizontal, and the other in a vertical, plane, and is used for measuring horizontal and vertical angles.

In the figure of the theodolite here presented, HRS represents an oblique view of the horizontal circle,

and mQn a direct view of the vertical one which extends to little more than a semicircle. The vertical circle is movable about an imaginary axis, coinciding with the radius OQ, which, produced, passes through the centre C of the horizontal circle. On the vertical circle is fixed

a telescope W, furnished with a spirit-level I; the telescope is connected with a movable radius OA, in contact with the opposite side of the vertical circle; and this radius is fixed to a vernier v, movable, by means of a screw, along the limb of the circle. When the centre o of the vernier coincides with the middle division Q of the circle, the axis of the telescope is then horizontal, and the instrument thus serves also as a spirit-level. A vernier to the horizontal circle is attached to the vertical circle at e, and is movable with it.

To measure a horizontal angle subtended at the instrument by the horizontal distance of two objects: Direct the telescope to one of the objects, and observe the number of degrees at e on the horizontal circle;

then while this circle remains fixed by means of a clamping screw, turn the vertical circle till the other object is visible through the telescope, and in apparent coincidence with the intersection of the cross wires, and note the number of degrees on the horizontal circle at *e*; then the difference between this and the former number is the required horizontal angle.

*To measure a vertical angle:* Direct the telescope to the object whose angle of elevation is required; then the arc, intercepted between *Q* and *o*, is the required angle. An angle of depression is similarly measured.

The plane table is frequently used in surveying. This instrument consists of a plane and smooth rectangular board fitted in a movable frame of wood which fixes the paper on the table *PT*, in the adjoining figure. The centre of the table below is fixed to a tripod, having at the top a ball-and-socket joint, so that the table may be fixed in any required position. The table is fixed in a horizontal position by means of two spirit-levels lying in different directions, or by placing a ball on the table, and observing the position of it in which the ball remains at rest. The edges of one side of the frame are divided into equal parts, for the purpose of drawing on the paper lines parallel or perpendicular to the edges of the frame; and the edges of the other side are divided into degrees corresponding to a central point on the board for the purpose of measuring angles.

A magnetic compass-box *C*, is fixed to one side of the table, for determining the bearings of stations and other objects, and for the purpose of fixing the table in the same relative position in different stations. There is also an index-rule of brass *IR*, fitted with a telescope or sights, one edge of which, called the fiducial edge, is in the same plane with the sights, and by which lines are drawn on the paper to represent the direction of any object observed through the sights. This rule is graduated to serve as a scale of equal parts.

A principle of measuring by triangles, which is alike common to land-surveying and the trigonometrical surveys of engineers, may be comprehended from the following figure. We wish to find the distance between two objects that are either invisible from each other, or inaccessible in a straight line from each other.

Let *A* and *C* be the two objects inaccessible in a straight line from each other, on account of a marsh. Measure two lines *AB*, *BC* to the objects and the contained angle *B*. In the triangle *ABC*, two sides *AB*, *BC*, and the contained angle *B*, are known; hence *AC* may be found.

Such a problem as the above is common in measuring heights and distances; and it will be understood, that the principle of throwing the area of any given field or set of fields into triangular spaces, is that pursued in all processes of land-measurement. In most instances fields are irregular in form; their outlines being often bent, with a greater width at one place than another. In such cases, after measuring the areas of the triangles, the odd pieces at the sides require to be measured, and their aggregate area added to the whole. We may illustrate the process of surveying as follows:—

The angular points of the large triangles or polygons,

into which a field is to be divided for the purpose of taking its dimensions, are called *stations*, and are denoted by the mark *o*; thus *o*<sub>1</sub> is the first station; *o*<sub>2</sub> the second; and so on. The lines joining the stations, and which are measured by the chain, are called *chain lines* or *station lines*.

Divide the field into triangles, or into triangles and quadrilaterals, the principal triangles or quadrilaterals occupying the great body of the field, and the rest of it containing secondary triangles and trapezoids formed by offsets from the chain lines. Measure the base and height, or else the three sides of each of the principal triangles, then calculate their areas by the rules in Mensuration of Surfaces, and also the offset spaces, and the sum of all the areas will be that of the entire field.<sup>11</sup>

*Example 1.*—Find the contents of the adjoining field from these measurements, *A* being the first, and *B* the second station:—

On chain line.	Offsets.
<i>Ag</i> = 150	<i>gC</i> = 141 to left.
<i>Ah</i> = 323	<i>hE</i> = 180 to right.
<i>Ai</i> = 597	<i>iD</i> = 167 to left.
<i>Ak</i> = 624	<i>kF</i> = 172 to right.
<i>AB</i> = 769	

The double of the areas of the component triangles and trapezoids are found, in order that there may be only one division by 2—namely, that of their sum.

*gi* = *Ai* — *Ag* = 447, *iB* = *AB* — *Ai* = 172, and *hk* = *Ak* — *Ah* = 301, *Bk* = *AB* — *Ak* = 145.

Twice the area of the triangle <i>AgC</i> = <i>Ag</i> · <i>gC</i> = 150 × 141	= 21150
trapezoid <i>CgiD</i> = <i>gi</i> ( <i>Cg</i> + <i>Di</i> ) = 447 × (141 + 167)	= 137676
triangle <i>DiB</i> = <i>Bi</i> · <i>iD</i> = 172 × 167	= 28724
triangle <i>AhE</i> = <i>Ah</i> · <i>hE</i> = 323 × 180	= 58140
trapezoid <i>hEFk</i> = <i>hk</i> ( <i>hE</i> + <i>kF</i> ) = 301 (180 + 172)	= 105952
triangle <i>BkF</i> = <i>Bk</i> · <i>kF</i> = 145 × 172	= 24940
Twice area =	376582

And area = 188291 = 1 acre 3 roods 21·26 poles.

These admeasurements, instead of being written out as above, are generally registered in a tabular form. A field-book, which is used to enter these measurements, is divided into three columns. The different distances on the chain line are written down in the middle column, and in the right and left-hand columns the offsets are inserted, with any remarks that may be made. The measurements on the chain lines are written in order upwards in the middle column, the first being written at the foot of the column, as the surveyor can thus more conveniently compare the measurements with the imaginary lines in the field.

In surveying a whole country by trigonometrical measurement, or in engineering plans for canals, railways, and roads, it is necessary to make allowance for the earth's convexity in all the calculations of levels. The degree of convexity, or departure from a true level, is reckoned to be about 7 inches and 9·10ths in the space of a geographical mile. (See *HYDROSTATICS*, No. 15.) In land-measuring, the scale of operations is ordinarily too limited to require any such allowance for difference of levels.

We have now, as far as our limits would admit, presented an outline of the methods pursued in land-surveying; and to those who design following out the study of this, as well as other branches of theoretic and practical mathematics, we recommend a regular course of instruction from Mr Bell's excellent treatises in *CHAMBERS'S EDUCATIONAL COURSE*—works so cheap, as to be within every one's reach.

## DRAWING—PAINTING—SCULPTURE.

DRAWING is an imitative art, by which the forms, positions, and relations of objects are represented on a flat surface. The faculties employed in this, as in other imitative arts, are possessed in a certain degree by all persons. Some possess these faculties in so high a degree, as to become fitted to exercise them as a profession, for the gratification of mankind at large. In others, they are manifested so moderately, that a protracted effort to make such persons become tolerable draughtsmen would only be labour thrown away. The majority of mankind, however, are so far endowed, as to be able, when instructed, to delineate any simple object, and to enjoy much pleasure from higher delineations produced by others.

The practice of elementary drawing at school, hitherto greatly overlooked, is calculated to produce the most beneficial results. As regards those who possess the faculties for design in a high degree of excellence, early practice will awaken those faculties, and furnishing them with stimulants to progress, secure the benefit of their ultimate exercise for the community. Lesser degrees of excellence will also be developed—such as would in vain perhaps essay excellence in the higher walks of art, but might become of incalculable value in connection with certain branches of manufacture.

As a means of elevating tastes and desires, and thereby embellishing what might be otherwise a routine of commonplace existence, drawing appears in its most interesting light. The person who has acquired a knowledge of botany, feels a new pleasure in examining the parts of a hitherto unseen plant; he who has acquired a knowledge of geology is interested in passing along a road, the side of which displays a deep section of strata, or from which he may view various granitic elevations; he who has acquainted himself with the principles of machinery, experiences an enjoyment in contemplating the intricacies of some great engine which another knows nothing of; and in the same manner he who has studied the art of drawing, discovers a source of new and innocent gratification in the innumerable forms and tints of external nature. Things formerly passed with a careless eye and a vacant mind, then assume a character which arrests attention and awakens thought. Those faculties of the mind which perceive and appreciate the figure, colour, and arrangements of objects, and trace in all a natural and appropriate beauty, spring up from a dormancy which might have otherwise known no interruption; a new association of our mysterious being with the physical world around us is practically established; and the value of existence becomes by just so much enhanced. Not surely that it is desirable that an absorbing interest should be created in all minds respecting the outward aspect of nature to the neglect of the more serious affairs of life. All that can be contended for is, that as many as possible should be rendered capable of looking with pleasure, instead of indifference, upon the beauties of nature, so that they may realise the benefit of this part of the intellectual and sentimental powers which have been conferred upon them; a portion of their nature which, like others, may be abused, but in its moderate use is not only a source of innocent pleasure, but may become the means of anticipating and supplanting many pursuits of a less worthy character. Nor, while the art is perhaps chiefly acquired with these views, may it be without some results of a more directly useful kind. In many situations—when wandering in our own, or roaming in foreign countries—we may see objects of which we would be glad to carry away some memorandum, and of which the slightest pencil sketch would be sufficient to awaken a recollection at any other time. And yet, for want of a few elementary lessons in draw-

ing, many of even those who travel for the purpose of informing the public, are unable to commemorate such objects, or, at the best, can give only a few rude scratches in outline, which a professional artist has afterwards to fashion into shape—a shape, of course, in which correct representation is not to be looked for. In this point of view, drawing takes its place, as a useful art, by the side of writing, being, like it, a means of description, and one which may occasionally be even more serviceable than that art, though certainly not capable of so general an application.

Referring to the volumes on Drawing in our EDUCATIONAL COURSE for a methodic series of instructions, our design on the present occasion is to present a popular view of what may be done by comparatively unlearned persons to acquire a knowledge of the art, including perspective, which is the foundation of all pictorial delineation. It will be understood, then, that our observations are addressed directly to the pupil.

### DRAWING.

Drawing is effected by various materials, as chalk, black-lead, or coloured pencils, Indian ink, &c. Drawings of a simple kind are made principally on white paper or Bristol board, but also sometimes on tinted papers, in which case the lighter parts are brought out by white crayons. Commence a study of the art by acquiring ease of hand, and in fact learn what the hand can do by its different evolutions. For this purpose, drawing lines with chalk on a black board is perhaps the best exercise. Either, therefore, on a board with chalk, or on paper with a pencil, learn to make drawings of lines, straight, curved, or a modification of either. Observe how much more beautiful is the appearance and effect of a curve in comparison with a straight line; and how nature delights in this waving of forms, of which we have examples in the bending of boughs in trees, the serpentine winding of rivers, and the curvilinear outlines of animals.

You may begin the drawing of objects by copying other drawings; but this species of exercise can only make you familiar with the manner in which lines answer the purpose of representation. To be master of the art, you must throw aside all drawings or copies, and learn to draw by your own ingenuity from tangible objects in nature and art. In this study the hand is taught to obey the conceptions of the mind. When, for example, we see a chair standing on the floor, we observe its shape or figure, its line of back, seat, legs, and all other parts about it. We then take a pencil, and bending the mind intensely on the form of the chair, try to define all the lines of the object on the paper or board. The more perfectly that the hand can obey the direction of the mind, while bent in thought on the object, so will the drawing more resemble the original in all its details.

The pupil, therefore, must be taught to call up the whole power of his mind respecting the appearance of an object, when he wishes to represent it by a drawing. On this, indeed, may be said to rest the fundamental principle of delineation in all its branches. No one can possibly attain even a mediocrity in the art, who does not, less or more, possess this power of recalling images to the mind, and of training his hand to act in strict conjunction with its dictates. The hand is only the instrument employed by the imitative faculty, and can do nothing useful without the strong concurrence of the will. Accomplishment in penmanship, and every other art in which design or figure is an element, is founded on this fundamental basis.

A plan of instruction in drawing has been lately introduced from the Normal School of Versailles into

England, and promises to be exceedingly suitable either for large classes or for private study. The pupils draw from solid forms, models of objects, not from drawings; 'therefore every line they make is a result of intelligence and a test of knowledge. Before they begin to delineate, they are made to understand what they are about to do, and the scientific rule they are taught to exemplify. This is, in our opinion, the only sound and true theory of elementary training in the science of drawing; for with the art this introductory course has nothing more to do than exercising the hand; its object is limited to teaching the pupils to see correctly the apparent forms of objects, and the seeming direction of lines, and to know the optical laws by which the real forms and actual direction of lines appear differently to the eye, according to the angle of vision under which they are seen. The pupils are not at first required to draw evenly or neatly, but only to express intelligibly, by rude lines, their comprehension of the rule exemplified by the model.'—*Art Union*. It may be added, that all such lessons will fall short of their desired end, unless the pupil acquire a proper idea of relative proportion in parts. He must learn to give each member its due size and no more, and to put all together to form a harmonious whole. Beginners usually commit ludicrous blunders in this respect, making a man's head as large as his whole body, or the windows of a house three times larger than they should be. Experience, and an attention to the following rules, will remedy these misconceptions:—

In pursuing the elementary lessons on solid objects, an idea of perspective will be unconsciously gained. It will be noticed that strong outlines mark the objects or parts of objects nearest the eye or in the foreground; while to make parts retire, or have an appearance of being at a greater distance, the lines must be made light, and the representations smaller. It is a matter of first consequence to bring out effects on a broad scale, not by repeated small markings, but by a comparatively few bold lines of greater and lesser thickness. You will observe that an object may be represented in two ways—first, by mere outlines describing its figure; and, second, by introducing strong shades among the outlines. Take, for illustration, fig. 1. Here the blades

Fig. 1.

of a plant are represented by a few thin and thick lines properly disposed, and by a little shading being thrown in to bring out the effect.

Fig. 2.

A just idea of the value of lights and shades may be said to be the beginning of all excellence in pictorial delineation; and you are recommended to lose no oppor-

tunity of acquiring it. The most simple objects afford examples. In fig. 2 we have a group of this nature, being a stone, a piece of broken wood, and the leaves of a tall grassy plant, such as may be observed in a field or by the roadside.

Mr D. R. Hay, in his excellent work, 'The Laws of Harmonious Colouring,' has the following practical observations on the method to be followed by young men in gaining a knowledge of drawing, with reference to patterns, decorations, and ornamental designs:— 'The course of study I am about to point out is within the reach of all—even those in the most humble situations of life. They will find it of easy acquirement, and a source of continual enjoyment, in the improved medium through which it will lead them to view the most ordinary productions of nature. She shall be their instructor; for all that I can pretend to do, is to point out to them a practical mode of receiving her lessons. To the uninitiated I therefore address myself; and let them not be dissuaded from beginning by having no predilection for the study—the more they persevere, the more they will love it.

In the first place, your attempts ought to be of the most simple nature, and on as large a scale as you can conveniently adopt: therefore begin by procuring a black painted board or slate, of from two to three feet square, and with white chalk practise the drawing of squares, circles, and ovals, without any guide to your hand. You may make yourself copies of these figures by the ordinary rules. When you are tolerably perfect at these, upon the proper combination of which depends all linear harmony, you may practise in the same way triangles, hexagons, octagons, and such other figures as arise from the various combinations of the straight line. Next, by your circular and oval lines, you may form crescents, circular and flattened volutes, regular undulations, and other figures, which arise out of their various combinations, first making an accurate copy to yourself of each figure by measurement, and continuing to practise until you can form it by the eye with perfect ease. Avoid forming your figures by little bits at a time; do each line as much as possible by one sweep of the hand. When you find yourself pretty perfect in this kind of practice, I would recommend you at once to draw from nature. You may take for your first subject a cabbage leaf, the larger the better; and persevere in copying it, full size, until you can represent it accurately in outline, with its principal fibres. You may then vary your practice by other simple subjects of a similar kind, until you find you can do them all with ease.

Before endeavouring to draw more than one leaf at a time, you must know a little of perspective. The most simple mode by which you will attain such knowledge of this art as will be most useful for your present purpose, is to hang a circular object, such as a hoop, between you and the window; set it a-moving gently round, recede a little from it, and you will find that, as one side of it retires and the other comes forward, the circle which it describes becomes narrower and narrower, until it disappears altogether, and leaves nothing but a dark line, as if a stick instead of a hoop were hanging before you. I recommend you to do this between you and the window, because the hoop will appear like a dark line, and you will thereby be better able to mark the change that takes place in the shape of the circle. Fix it in various positions, and draw from it, and observe that it is a different figure from an oval. You may now hang up your cabbage leaf, or that of any other large and well-developed vegetable, and you will observe the same change in its figure as it turns round. Make an outline of its shape while its front is half turned from you, then bring it from between you and the light, and place it where the light will fall upon it, with its face half turned from you, as when it hung before the window. Take your outline, and within it draw the principal fibres as you see them. To do this properly will require a great deal of practice, but it will pave the way to your being able to draw the most complete groups of

flowers and foliage that can be placed before you. You may now hang before you a small branch of any tree or plant, with two or more leaves upon it—the larger the leaves are the better—and endeavour to make outlines of them, varying their shape according to their perspective, as already described; be particular on this point, for a great deal depends upon it.

You may now lay aside your chalk and slate, and provide yourself with a few sheets of common cartridge-paper, and some pieces of common charcoal—that made from lime-tree is the best. Stretch a whole sheet of your cartridge-paper upon your board by a wafer or a little paste at each corner. Place before you a cabbage, cauliflower, stalk of dock-blades, or any such large vegetable, and they will be more picturesque if the outer leaves are hanging loose. Copy these carefully in outline, using your charcoal gently, that any inaccuracy may be easily dusted off. A large thistle with its foliage is likewise an excellent example, but more difficult. Indeed you cannot go wrong in your choice—hemlock, fern, nettle, are all worthy of your study. From these the richest and most effective of Gothic ornaments were taken by our forefathers. The more you study such subjects, the more beauty and grace you will find in their forms.

When a considerable advance has been made in the elementary department of drawing, it will be proper to go on to the higher stage of perspective drawing, in exact accordance with the rules on the subject. For this you will require the following

*Requisites for Drawing.*—Among the various articles required in systematic drawing, the first place may be given to a wooden board of a convenient size, or about two feet in length by eighteen inches in breadth; it should be perfectly smooth, and perfectly squared. On this board the paper on which the drawing is to be executed should be properly fastened. This is done by damping the surface of the paper with a wet sponge, and after it has fully expanded, fastening it down with a little thin glue round the edges; it should be laid on the board evenly, and left to dry in the air.

The next requisite is a flat rule called a T-square; this is a thin straight-edge, or rule, attached at right angles to a short piece of wood much thicker, so that when the cross-piece is moved along any side of the board, the rule will project across the paper, and by its edge pencil lines may be drawn straight from left to right and from top to bottom. To test the accuracy of the square, let other lines be made from the opposite sides of the board; and if they agree with the former lines, by being parallel to them, all is right. On these guiding lines, or rather indications, the correctness of the drawings will materially depend.

To these must be added a pair of compasses—an instrument so well known, that it is only necessary to remark, that the points should be just as sharp as to hold on the paper without piercing it. The compasses should be held lightly by two fingers and the thumb, and moved with the least pressure which the operation may require.

These simple implements will be sufficient, until a knowledge of the art suggests the necessity for a case of mathematical instruments.

Paper may be purchased of all qualities; for early practice, it is sufficient for it to be what is called *hard*; that is, able to endure being written upon with common pen and ink.

Black-lead pencils are of various qualities: a soft pencil gives off the lead too freely, and will not retain its point; a hard pencil wounds the surface of the paper, and cannot be easily obliterated; therefore the medium pencil is best for drawing perspective. The wood should be carefully cut from its point, and the lead sharpened by being gently rubbed on a file, which produces a better point than can be formed with a knife.

Indian-rubber, or a clean crumb of bread, to take out lines incorrectly drawn, is also necessary.

Every student of drawing is supposed to be acquainted with the form of acute, obtuse, and right angles, circles,

ellipses, and other simple mathematical figures, and therefore we need occupy no time here in describing them: those who wish to refresh their memory on these matters are referred to the article GEOMETRY.

## PERSPECTIVE DRAWING.

The study of perspective is commenced by acquiring a knowledge of certain principles, and the technical appellations by which they are described. The first thing which you will attend to is the existence in all correct perspective drawings of a *horizontal line*. The horizontal line is always the height of the spectator's eye, and of course fields or hills may be above this imaginary line in a picture. In the following diagrams the horizontal line is always marked H. There is a certain point on the horizontal line to which the eye is directed; this is called the *point of sight*, and in the following diagrams is marked P.

As noticed in the article OPTICS (No. 16), the apparent magnitude of any object is influenced by its distance from the eye: if near, the object seems large; if remote, it is small. It is, then, a most important principle in perspective drawing, to regulate the size of the objects marked according to the distance at which we wish them to appear. We have a good example of this gradual diminution of objects as they recede from the eye, in the manner in which a long avenue of trees seems to close in a point at its further extremity. It would be possible for a person, unskilled in the rules of perspective, and merely by the general directions already given, to give a representation on paper of the manner in which objects thus seem to diminish, as, for example, a row of posts; but as mathematical science gives exact rules on the subject, no one need trust to chance, but appeal to principles of unerring accuracy. We crave attention to these principles, which we endeavour to illustrate by certain lines in the diagrams which follow:—

Figure 3 represents a quadrangular drawing, of which AB is the base. Across the picture, at rather

Fig. 3.

more than a third of the height, is a line H, representing the horizontal line. On the horizontal line, a point at P is the point of sight, and to this point all objects are diminished in proportion as they approach it. Thus a road represented by the two lines C D tapers to a point at P, and a row of posts E diminish towards the same centre of observation.

The horizontal line which, it will be perceived, regulates some important points in pictorial delineation, may be placed high or low at pleasure; but it is generally regulated in its elevation by the nature of the subject to be drawn. If placed high up, it leaves too small a proportion of sky, and produces what is called a *bird's-eye view*; if placed near the base, unless the scene be mountainous, the proportion of sky will be too great. In general, the horizontal line should be drawn at about one-third of the height of the picture. The point of sight may also be fixed at pleasure; but its best situation is removed from the centre towards one of the sides; if directly in the centre, the perspective would have too formal an effect.

When an object having angles, as a box, stands on a base parallel to the horizon, and two of its sides or sur-

faces can be seen, that which is farthest from the eye will recede according to the situation of the point of sight. Place a box, as in fig. 4, immediately in front of the eye; AB is its bottom or base, and EF is the farther edge of its top. AB, the base, being parallel to the horizontal line H, the point of sight will be at P, and the visual rays from the upper corners of the box will centre in P, because the eye is in front, and above the object. Any alteration of the position of the box, or the eye, will consequently require a corresponding arrangement of the laws of perspective.

Fig. 4.

Place the box toward the farther side of the table, immediately in front, and lower the eye till the horizontal line is one-third down the box, when the top will be lost sight of; there let the eye be fixed, by resting the chin on any convenient object, and the front, or only one side of the box, will be seen. Then let the box be moved to the left, in a straight line, the position of the eye being retained, and a second side of the box will come into sight; its receding lines or visual rays will then be centered in the altered point of sight, and the side in front will retain its form, because its base is parallel with the horizon. When this experiment has been made, and the situations of the box and the eye have been considered—presuming the box to have been a cube—proceed to ascertain the mode of representing this object according to the rules of perspective, referring to the natural appearance of the box occasionally, the more effectually to fix the mutual resemblances in the mind. Fig. 5 will show the process by which all the particulars may be demonstrated. Presuming the paper is fastened down on the drawing-board, the T-square and pencil ready, commence thus: Apply the T-square and draw the base line AB, and also the boundary of the picture CD. Then draw the horizontal line H across the paper; this may be fixed at pleasure, but parallel to AB. Then find the half of the base AB, and draw a perpendicular beneath the picture to O, and on it place the profiled angle of 60 degrees, just at that distance which, by continuing the sides of the angle, they will intersect the extremities of the base, and together form an equilateral triangle, as AOB: this must be strictly attended to. Now, as before observed, the point of sight is better when removed from the centre of the picture; and taking a station to the right, by a horizontal line from O to S, this be-

Fig. 5.

comes the station whence the picture is seen, and the point of sight is therefore found by the perpendicular line from S to P on the horizontal line. Now, as a vanishing point is required to determine the width of the receding side of the box, the profiled angle of 90 degrees is to be placed at S on the perpendicular PS, and the side line continued until it intersects the horizontal line at V, which fixes the vanishing point: this also must be strictly attended to. It will be observed that the angle at S is one of 45 degrees, being the half of the profiled angle of 90.

We now call attention to the situation of the eye, which is always on a level with the horizontal line; therefore the true position of S is immediately in front of P, or, as if the perspective lines beneath the picture could be raised up to the level of S, and fixed at that distance from the picture, to show the true situation of the eye when viewing the object. The front square shape of the box may then be drawn in, occupying less than half the base of the picture, in order to show the perspective, as at fig. 3; then from the nearest perpendicular of the box draw the visual rays from the top and the bottom of the square to P, which give the diminutions. Now a line drawn from the corner of the box near A to the vanishing point V, will intersect the diminishing line, which gave the receding base of the box at L; and a perpendicular line from L to K on this intersection, will give the true representation of the square box as seen in perspective. If this were a cube of glass, the farther sides would be seen, as shown by the finer lines in the diagram.

Repeat this study in different sizes, referring to the natural appearance of the box, in order to feel, as well as see, the coincidence between that and the object produced by the rules of linear perspective. It is of importance that this diagram should be thoroughly understood, because many of the rules employed in it are frequently required.

The boundary of a picture, or the plane, may be of any proportions. The base is marked, in fig. 3, A, B. The perpendicular, from the middle of this base line, assists in finding the situation for the angle of 60 degrees O, the width of the base, measured from the extremities to the perpendicular O, forming an equilateral triangle, as AOB. This is a rule, whatever may be the size of the picture; it also shows the proper distance at which a picture should be viewed. This expanse of vision, at an angle of 60 degrees, is marked in the diagram O, and places the point of sight in the middle of the picture, which is very often objectionable; therefore a line parallel with the base is drawn from O, and on this line the better station is taken, which is marked in the diagram S. Now the horizontal line H having been taken at pleasure, a perpendicular drawn into it from S will give the point of sight at P, into which the visual rays are drawn that regulate the receding side of the object. The vanishing point V is entirely distinct from the point of sight, of which there can be but one; but vanishing points may be numerous. This, marked in the diagram V, is of great consequence, for by it is determined the proper width of the object, by the line which intersects the visual ray from the base of the box A to V, as at L; and here the perpendicular to K, which intersects the upper visual ray, completes the perspective form of the object.

No objects better exemplify rules in perspective than articles of household furniture, such as boxes, chairs, tables, and chests of drawers. We direct your attention to the following illustrations:—Fig. 6 exhibits a parlour chair and a footstool. Observe that the chair stands with the corner of its seat nearest to the spectator, the point of sight being in the middle of the picture. The receding sides of the chair have their respective parts regulated by diagonals to their vanishing points. The footstool stands on a line parallel to the base, and therefore its visual rays tend to the point of sight in the centre of the picture. These may prepare the mind of the student to consider that objects,

## DRAWING.

when differently situated, have each their vanishing points regulated by the angle at which they are viewed.

Fig. 6.

We recommend you, on all occasions, to draw the horizontal line so far on either side, that it will be intersected by the diagonals, which are to be drawn at an angle of 90 degrees from the station, into the horizontal line, where they determine the vanishing points. These are only indicated in the diagrams by the direction of those lines, and the words 'to V 1' or 'to V 2.'

In fig. 6, the base line A B is drawn, its centre determined, and the perpendicular drawn to O; the angle of 60 degrees is taken in agreement with the base line, making an equilateral triangle, and the point of sight P is fixed on the horizontal line H. The vanishing points are found by the angle of 90 degrees at O, projected on either side to V 1 on the left, and V 2 on the right, as before described. All the diminutions of corresponding ornaments on the back and front legs of the chair are drawn to V 2, while the side of the chair is regulated by V 1. The footstool is placed parallel to the base on the line C D, and its diminution regulated by the rays E P and F P. The diagonal G from the leg of the footstool D, to the vanishing point V 1, would determine the square of the stool, or the position of the farther leg, at the point where it intersected the ray C P.

Fig. 7 shows the perspective lines required to represent a writing-desk placed diagonally on a table which stands on the base line. The base of the picture is drawn as A B, the centre is taken, and a perpendicular drawn to O, for the angle of 60 degrees. The horizontal line is drawn at H. The parallel is drawn from O to S, and there the perpendicular to the horizontal line fixes the point of sight at P. Then the angle of 90 degrees is taken at S, and the sides being projected to the horizontal line, gives the vanishing points V 1 on the left and V 2 on the right. Now the table being seen in front, or on the base line, the visual rays from the legs and the top are drawn to the point of sight P. The table being supposed to be a parallelogram, its side, seen in perspective, will be about half its width seen in front; therefore let half the space seen in front be set off from the leg on the right; and the diagonal from that half to V 1 will give the diminution of the side of the table, where it intersects the ray from the front leg to the point of sight P, at R. A parallel line from this to the ray from the other front leg will give the situation T for the most distant leg. The writing-desk being presented with its corner to-

wards the spectator, both sides will require their receding points, which are determined by the vanishing points V 1 and V 2. Such familiar objects should be drawn, by which the more readily to fix in the mind of the student the leading principles of linear perspective.

It will be seen that, when an object has its base line parallel to the horizon, the point of sight is in the picture, and that it is arranged in agreement with the angle under which the object is viewed. Thus if it be an object which has four sides, and one of those sides be immediately in front of the eye, the visual rays will be hidden, because the point of sight is in or behind the object. It will also be seen that if the object be moved on either side, or the point of sight be altered by a change of station, the visual rays determine the receding side of the object immediately on a second side being seen.

If the base line of an object be removed from its parallel to the base line of a picture, the angle under which the object is viewed becomes altered in strict conformity with its changed position, the particulars of which the student may ascertain by placing an object in the various positions.

Suppose a chest of drawers, or a cube, to be placed and seen as in fig. 3, and while the nearest corner is to act as a pivot, the end near A to be moved so as to

Fig. 7.

cause a space between the base line of the object at that end and the fixed base line of the picture, the angle of vision would require that the base and top lines of the object should have their vanishing points. The object could be moved thus at different times, until that which in the diagram is the receding side would become the front, and each position would require a diagram; but the student is presumed to have become acquainted with the fact, that at each pause in the movement of this object on its pivot, there will be exhibited a diminution on one side proportionate to the increase of the other side; until, by continuing these rotatory movements of the object, that side which was at first presented obliquely, becomes the front, and its base parallel to the base of the picture. The original front of the object, by the revolving movements, will have been lost or hidden, exactly in proportion as the receding side advanced to the front. Thus the vanishing point extended as the advancing side became more evident, just in proportion as the receding side diminished. Make these experiments, and observe, on the first change of position deviating from a parallel with the base of the picture, that the vanishing point V 1 was

required, and so far removed on the horizontal line on the left, as perhaps to require an angle of 80 degrees at the station, while V 2 on the right would then require an angle of 10 degrees. Any subsequent change of position in the object will alter the angles for the respective vanishing points, and these together always making an angle of 90 degrees.

Fig. 8 shows the method by which the situations of windows may be properly drawn in the representation of a house, seen obliquely. Draw the base line AB: find the angle of 60 degrees on the perpendicular from the centre, and mark the station S: determine the horizontal line H, and the point of sight on it, perpendicular to S: find the angle of 90 degrees, and draw the lines to the vanishing points V 1 and V 2: draw the nearest perpendicular of the house C, and fix where the nearest windows are placed, also their height and width, DE: draw these diagonals to the vanishing point V 2; they regulate the diminution of the heights of all the windows: draw also the cornices and the base lines; then draw a fine line F parallel to the horizon, and touching

Fig. 8.

the perpendicular C; then, with the compasses, take the measure of the space between the perpendicular C, which is the corner of the house, and the edge of the window D, and mark it on the line F as at 1; then take the width of the window E, and mark it as at 2. It is better to have a second pair of compasses to prevent mistake in the alternate alteration that is required, or the space for the windows may be marked with the point of a needle on a piece of writing-paper, and then marked off carefully on the line F; then the compasses will mark the space between the windows only. The small projection which separates the centre from the wings must be noticed, as at G; then the space with compasses 4, then the window 5, then the space 6, then the window 7, then the space 8, then the window 9, then the space 10, then the window 11, then the space 12, then the window 13, then the space 14. This being the farther extremity of the centre of the house, the corresponding projection to G must be noticed, as being so much of the next space hidden behind the projecting centre; it will therefore be marked 15, then the window 16, then the space 17. These compose the spaces and widths of windows as seen in the front of the house; and it must be mentioned, that the points which have been made on the line F, must be perfectly true on the line, or the truth of the diminution will be impaired. Now assume a point about the middle of the house, on

the horizontal line, as at K, and draw diagonals from all the points made on the line F into the point K, observing that the point of the pencil runs into both at every line. A needle may be placed at K, against which the straight-edge may be pressed, to assist in drawing the diagram correctly. Now the diagonals which regulated the diminution in the height of these windows, as drawn to V 2, will be intersected by the radii drawn from the point K into the marks on the line F, and those intersections will show the diminution of width according to the laws of linear perspective.

As this diagram may be crowded with lines, you are recommended to examine the intersections carefully, and mark the forms of the windows with a hard pencil, and then draw in all the perpendiculars as regulated by the radii on the diagonal lines. If in this state of the diagram there should appear any confusion, it will be far better to commence another; and the larger the drawing is, the less risk is there of disappointment. The side of the building—that is, the wing and the portion of the centre seen above, with the little projection at G, are drawn by diagonals to the vanishing point V 1.

You are advised not to pass this diagram without having obtained a perfect knowledge of the principles by which the diminutions are regulated. Difficult as this may appear, it ought by all means to be attempted, for it cannot be too strongly impressed on the mind, that no perfection in drawing, no delicacy in finishing, nor boldness of effect, can atone for deficiency in perspective. When a little progress has been made in this, so that the judgment is prepared to understand the arrangements which objects must undergo to be correctly represented on a flat surface, a scene in nature can be sketched without any material difficulty.

Fig. 9 represents a method by which archways are put into perspective:—

Fig. 9.

The base AB, the horizontal line H, and the point of sight P, are determined as in the preceding diagrams. In this it will be seen that if the point P had been retained in the centre of the subject, the sides of each respective arch would have been alike; to obviate this, P is placed a little to the left of the centre.

This is a subject which may often be met with, and you are advised to study such objects in nature, be they of one or more arches; ever remembering that the station must be preserved with the head towards the point of sight; the eyes only are to be turned from one part to another. You will thus practically learn the distance at which to take a station for such studies. If it be taken too near, too little of the subject will be seen. If it be taken too far off, then there will be more expansion than is required, and the subject will not show the minutiae.

Suppose such an object as fig. 9 to be in front of the draughtsman: the piers between the arches should be sketched as perpendicularly as possible, and the arches turned by hand; then the depth of the receding sides, as nearly as the judgment may direct, and as much of the masonry as may point out the perspective of the

## DRAWING.

subject: then, while all is fresh in the memory, attach the sketch to the drawing-board, and by the T-square draw the base A B, the horizontal line H, the point of sight P, and the vanishing point V 2: then, by the T-square, correct all the perpendiculars and horizontals; draw the line C C, which is the chord of the smaller arcs, and D D, which is the chord of the large arc, and observe that the perpendiculars intersect the line C, and those at the centre arc at D: then find the centre for the arc M, and describe it correctly from one perpendicular into the other: do the same from their centres to the smaller arcs; and thus the superficies of the subject will be defined: then draw the visual rays from the base of all the perpendiculars E, and from the intersections on C C and D D, to the point of sight P, which give the receding lines for the visible sides of the archways. If the piers be square, a line drawn from the base of the perpendicular of the centre archway E, to the vanishing point V 2, will give the perspective width of the receding parts. If the piers be one square in front, and two squares deep, mark off a square to the left of the perpendicular, as at G; and a diagonal drawn thence to V 2 will give the receding depth where it intersects the visual ray E P at K. At this intersection draw the horizontal line I; and where this intersects the visual rays at E P, as at K, raise the perpendiculars till they intersect the visual rays C P and D P, as at L L. Thus will the receding sides of the archway be determined. To find the arc at the farther end of the subject, draw the horizontals L L; and the visual ray M P, where these intersect at N, is the centre on which the arc may be described. The smaller arches are to be found by a similar process.

Now the correcting of such a sketch by the application of the rules of perspective, will show where the eye and hand have failed in giving a faithful representation of the object. Therefore, again visit the spot, taking a station strictly in agreement with that in the drawing, and compare the corrected lines with those which nature will present. Let all be rigidly examined, and the result will not fail to be satisfactory.

We recommend that every opportunity should be taken to sketch such subjects from nature; they furnish excellent studies for linear perspective, and one such study would convey more information than the copying of a dozen drawings or diagrams.

### SKETCHING FROM NATURE.

Having acquired a certain facility of hand, and mastered the principles of perspective, you may proceed to the more agreeable study of sketching from natural scenery. At first, do not attempt any difficult or complex subject. Select some assemblage of ordinary objects, such as may be thought agreeable in themselves, and likely to be represented with ease and satisfaction. The scene selected should not contain more than three or four objects of different kinds—such as a cottage, one or two trees, and a small rustic paling, with perhaps the addition of a little glimpse of background. You will observe that an artist rarely ever takes an object in its broadest and most regular form: he never represents a house, for instance, as if he had taken up his position right in front of it, as an architect would do; nor would he paint a row of trees at a right angle to his own position, seeing that the effect of such representations would be tame and formal. He endeavours to catch the careless grace of nature, as she appears to casual observation. A house, particularly, should always be viewed from a point a little aside from the front, so as to bring in as many of its angularities as possible. A group of natural objects should be represented as if the draughtsman had just by chance got his eye upon it; and yet the selection of a point from which this effect may be obtained must be a matter of study. For an early lesson in sketching from nature, it is enough that the objects be merely drawn in outline: to fill in details, and give the full effect of light and shade, must be left to a future period in the career of a young artist.

As an example of the scenes which may be selected for early sketches from nature, fig. 10 is given, being simply a cottage, backed by a few trees, and having some broken ground in front, while a glimpse of the sea is obtained at the side of the picture. The station of the draughtsman is here at S, in order that the cottage may not appear to have been viewed formally, and that the trees behind may give to the scene its neat pyramidal form, while the broken grounds in front communicate boldness of character, and the straight line of the sea at P (which is the horizontal line) affords a pleasing contrast to the other lines of the drawing.

Fig. 10.

It will be remarked that the cottage stands on a line parallel to the base A B; the point of sight P is perpendicular to the station S; consequently the rays that regulate the side of the chimney, the upper and under lines of the roof, and the window on that side of the cottage, all centre in P.

Provided with a sketch-book (measuring perhaps 10 inches long by 7 inches broad), the first thing to be done is to select a station from which the drawing is to be executed. A difficulty may present itself respecting the size of the proposed drawing; but the dimensions may be determined in a very simple manner. Hold up the sketch-book in front, with one eye closed, and the space in the scene covered by the book is that which may be drawn; of course, the farther off the book is held, the less of the subject will be covered. When the extent of the scene is arranged, the book may be gently lowered, and a few dots made on the top margin, merely to point out the relative situations of particular features, as the width of the cottage, and the trees. Then remembering to preserve the station, mark the point of sight on the distant horizon. Do not be in haste, but judge of the relative distances of the most prominent parts—such, for instance, as the gable end of the cottage and its length—and tenderly mark them on the places to be so occupied. When these or more dots for guides have been placed, examine their relative distances, and compare them with the objects, by holding the sketch-book out in front; so as to see the agreement between them over the margin. To arrange these particulars well at first, will save much trouble in obliterating falsely-drawn lines. Be careful, in sketching, to preserve the perpendiculars of walls and chimney; that is, to draw them vertically or at right angles with the base line, which is now the lower edge of the sketch-book.

To prevent the hand from injuring the sketch as it proceeds, commence on the left and proceed to the right. Endeavour to sketch the lines with a lightness of hand, or with what is called freedom, the effect of which is very distinct from lines drawn by a straight-edge: let them be rather broken, or a little wavy, yet having the general appearance of straightness. Let the masses of foliage be sketched with the same ease and confidence that the capital letter E, or the flourish of the D, are made in writing. Sketch the grounds, in their different undulations, rather more angularly, or as if ruggedly dashed in, and strengthen the lines where separation of parts seems to be required.

In examining the objects of which a scene like the foregoing is composed, you will observe that the lines for the cottage have one character, the lines for the trees another, and the lines for the ground a third character, which detach the objects from each other. A simple outline of these three forms is sufficient to be aimed at, for the introduction of more markings or separations would only tend to confuse early studies.

If the lines, on a first attempt, be not all which could be expected, they furnish a proof that the mind is in advance of the hand, and should operate as a stimulus to exertion. In a few studies you may discover that, by beginning with a cut point to the pencil, it gradually wears away, and gives an increasing thickness of line; this is often very advantageous, for as the sketching advances to the foreground, the bolder lines of the pencil contribute to the separation of parts, to regulate distances, and give a more spirited effect to the subject. You will also discover, after a little practice, that by a gentle twist of the pencil, a fresh point or surface will come in contact with the paper, and with it a finer line may be drawn. Occasionally, by pressing harder on the pencil, an increase of power will be communicated to such parts as may require separation or additional spirit, as on the rude line which forms the foreground in fig. 10, and gradually on the pathway to the cottage door.

Suppose a scene to consist of two or more plans, as the remains of a castle on an irregular surface, with a mass of trees in front, and near it, as the principal or leading feature of the scene, an arm of the sea, and remote hills forming the background or distance, and a rude foreground. We shall suppose that a scene of this nature, as represented in fig. 11, can be conveniently visited. Commence by selecting a station that will present a variety of forms or opposition of character, such as lofty objects contrasted by small objects, which will prevent the appearance of equal heights or parallels, and also prevent the scene from being crowded or closed up. The castle toward one side of the pic-

Fig. 11.

ture, and the distance on the other, so as to form an irregular diagonal mass, are in better relief than if the building with the trees were more in the middle of the subject. The opposition of angular to circular forms produces a pleasing effect in a sketch, and should be observed. If the perpendiculars of a ruin be broken, the general appearance must be that of standing upright; for however mutilated towers or walls may be, there will still be evidences of their having been properly constructed. When these particulars shall have been considered, proceed to arrange the situation of the principal mass, by dotting on the edge of the sketch-book, and by faintly indicating the forms, determine the horizontal line, observing that hills may appear far above: in fig. 11, it is at H on the extremity of the water, the station is at S, and consequently the point of sight at P, into which are drawn the visual rays, or lines which regulate the receding sides of the towers. These and the perpendiculars being arranged,

they may be boldly sketched in, and the trees freely marked, in a character partaking of the semicircular; the fewer markings the better, for it is the useless separation of parts composing a mass that destroys the breadth and boldness of a sketch. The distant hills may be tenderly indicated with a fine point, and the foreground may be coarsely defined with a broad-pointed pencil, in order to detach it from the parts more distant. Here and there an additional spot or touch of the bold pencil may be given, to assist in preserving the gradations of distance.

The same object in nature will often present many excellent subjects for the sketch-book; even moving to a distance of fifty yards may present a scene of increased interest. Do not, therefore, fail to take advantage of such stations, and sketch an outline from each, in order to exercise the judgment by comparing the subjects afterwards. It is also useful to ascertain how nearly the eye has determined the truth, by applying the rules of linear perspective to every sketch at the earliest convenience. Many advantages arise from two or three students sketching the same scenes in company, for various valuable remarks are thereby elicited, tending to the mutual benefit of the party. The sketch-book should be preserved complete, as containing records of advance in judgment and correctness of delineation.

In drawing from nature, as in penmanship, every person may be said to possess a *manner* of his own. Some draw stiffly, and others with remarkable freedom. You are recommended to catch the tone of those who form their sketches in a bold and free style, but by no means imitate any one. Your object ought to be to draw scenes with *natural truth and beauty*, regardless of all *mannerisms*. At first you can scarcely avoid drawing with a certain degree of formal stiffness, but animated by a desire to excel, and exercising taste and judgment, your practice will improve, and your sketches will not fail to meet with approbation. Whatever be the difficulties you encounter, others whose works you admire were at the outset equally embarrassed; for rest assured that in most cases in which great proficiency has been attained in the art of delineation, no small degree of trouble has been endured, and many failures have taken place, before the artist was finally successful.

**DRAWING FOLIAGE.**—To draw correctly the various kinds of trees, with their respective characters of foliage, requires the most careful study and frequent exercise from nature. In an elaborate work on Landscape Drawing, published by Leigh, London, the following remarks occur on the characters of foliage:—'When a tree is near the eye, the leaves are distinctly separated from each other; their particular form, the insertion of their stems into the branch, the perfection of their local colour, are all apparent. Remove this object to the second plan, the foliage assumes masses, retaining the character, but the tone is altered; the separation of parts is no longer evident, yet it is recognised as the object previously inspected. Remove it still farther from the eye, the masses assume a uniform tone, relieved by indications of light and shade, softened by the intervention of atmosphere. Remove this object still more distant, it is rendered indistinct, and forms a portion of the mass of light or shade in which it may be situated. Nature presents these appearances to every inquiring eye, and the mode of representing them must depend on the perseverance of those who delight in transcribing them into their sketch-books.' This is so just, that the student might imagine the tree first inspected retiring gradually into indistinctness, and displaying, as it receded, the due portions of aerial effect. It also teaches how tenderly the outline must be expressed in extreme distance, how much more evident the marking may appear in the mid-distance, how much more defined the form becomes by light, shade, and markings, on the second plan, and how distinct the expression of character and power of touch ought to be as they approach the eye or the foreground.

## DRAWING.

Fig. 12. The willow has been represented by perpendicular markings, terminating in a point, to give the

Fig. 12.

idea of its pendant foliage. A broad mass of light is usually preserved, and an increase of markings is given to one side of each subdivision of foliage, with considerable power of characteristic markings on the shade-side of the tree, besides an occasional repetition of touch for effect.

The fir has been represented by short angular markings connected with each other, much like the zig-zag scratch with a pen to obliterate an incorrect word. These markings are continued in agreement with the projections of the branches, and are repeated with increased power on the shade-side of the tree. A few slight markings are given on the extremities and beneath the masses to indicate the existence of foliage on the farther side of the tree.

The elm has been represented by escalops in a semicircular direction, so distributed as to give the idea of thick foliage; the masses are separated by detached markings, indicating the same character, and their rotundity given by repetitions, with occasional increase of power. A few dots on the extremities will relieve the harshness of the outline, where the escalops are too evident or regular.

The oak has been represented, as in fig. 13, by a character which partakes of angular and broken circular markings, intermingled with dots and sharp touches. The lighter parts are pencilled tenderly, and the shade portions are repeated upon, with additional power given by sharp angular markings.

We mention these varieties for the purpose of showing that foliage is not to be represented by distinctly portraying every leaf, but by a bold grouping and superficial outlining; the purpose being served by merely a general representation. Suppose a tree is to be selected for placing in the foreground of a drawing, where its peculiarities are required to be displayed. Let the growth of the branches be observed; a straight line is rarely to be seen, nor do they spring from each other with uniformity; there is usually an undulating line, often graceful, or a wild luxuriance, ever pleasing, in these supports to the foliage. Let the effect of the leaves which may compose a principal mass be indicated, not the outline of a leaf or leaves, which would prove labour in vain, but what is seen as much by the imagination as the eye—that is, not the detail, but the effect. If too much regularity appear, destroy it by projecting a touch or two on the extremities, and attack any formality by additional markings, in conformity with the character adopted. Oftentimes the mere waving of the pencil, or a powerful repetition with the broad point, will not only remove a monotonous appearance, but communicate characteristic spirit and effect.

Experience has shown that while students could sketch the extremities of various branches of trees

with good effect, they have felt embarrassed in giving a corresponding correctness to the mass, or masses of

Fig. 13.

foliage, belonging to the same tree. This has arisen from not having duly considered that each mass required to be treated as a centre, from which the character should be spread towards its respective boundary, with such discrimination as to obviate all appearances of formality, and then, by the introduction of repetitions of markings and touches, to arrange the separate parts, so as to preserve but one central mass, however it might be situated. A few trials, with the observance of these particulars, will remove the difficulty. Sometimes the hues of nature in their variety may at a future time be added. The light and shade in Indian-ink cannot be thus used as a basis, because under colour it is injurious to transparency. The light and shade in bistre is rich in mass, powerful in touch, and susceptible of giving transparency, with a high degree of finish. Either may be adopted, as the succeeding hints will apply to one as well as the other. Cakes of Indian-ink, of bistre, or of neutral tint, may be had of the venders of colours for artists. They should be free from grit; and when they are well ground, and duly incorporated with gum and white sugar-candy, they will deposit no sediment.

*Flower-Drawing.*—In connection with the drawing of foliage and trees, we should particularly recommend the practice of flower-drawing. At first you may copy drawings or prints of flowers, with a view to catching the mode of delineation in groups; nature, however, in this as in everything else, must be your true school, and to that we direct your attention. We press this advice in a particular manner on young mechanics who are studying ornamental design with a regard to their professions. No doubt, examples of ancient and modern ornament are of great value in this branch of drawing; but as Mr Hay justly remarks in his work on Colouring, 'flowers are your best practice, as you will now have obtained freedom of execution. To those who have gained a facility in copying the beautiful forms which prevail in the vegetable kingdom, and who have had such instructions in the use of water-colours as may enable them to copy individual flowers with ease, I would recommend the acquirement of a thorough knowledge of the laws of harmonious colouring. They will then be able to group and arrange flowers in the most agreeable and effective manner in regard to colour, as their previous experience must have taught them to accomplish in combination of form.

Dr Ure says, that "the modes in which taste is cultivated at Lyons deserve particular study and imitation in this country. Among the weavers of the place, the children, and all persons busied in devising patterns, much attention is devoted to everything in any way connected with the beautiful, either in figure or colour. Weavers may be seen in their holiday leisure gathering flowers, and grouping them in the most engaging com-

binations. They are continually suggesting new designs to their employers, and are thus the fruitful source of elegant patterns." Hence the French flower-patterns are remarkably free from incongruities, being copied from nature with scientific precision.

All these facilities for the improvement of our fancy manufactures are within the reach of the most humble. The pursuit of such a course of study as I have endeavoured to point out, would not only augment their sources of innocent pleasure, but lead them to other instructive pursuits. The youth, in searching for the most graceful and picturesque plants in nature's most profuse and wildest productions, would be naturally led to commence the study of botany, for he would then have some interest in the inquiry. And it may be easily imagined with what avidity the more advanced would add to his knowledge of that pleasing science, or the gratification he would derive from the study and practice of horticulture.

I need scarcely (continues this writer) point out the advantages to be derived from the cultivation of flowers by those engaged in designing ornamental patterns. The productions of a well-managed flower garden to such would be, in my opinion, of more real utility, as objects of study, than the contents of the Louvre. In those productions of nature they will find the most exquisite beauty and elegance of form, and even in single flowers, the most perfect combinations of colouring.

In saying that the study of such subjects is of more utility to the ornamental designer than that of those great works of art which have been the admiration of ages, I do not mean to undervalue the benefit that any one, and especially the artist, may derive from studying works of this description. I am aware that "the eye has its principle of correspondence with what is just, beautiful, and elegant, and that it acquires, like the ear, a habitual delicacy, and answers, with the same provisions, to the finest impressions. Being therefore versed in the works of the best masters, it soon learns to distinguish true impressions from false, and grace from affectation." I have therefore not the least doubt that those who have risen to some degree of eminence as ornamental designers, would reap great benefit in attaining a knowledge of the various styles and subtleties of colouring, by carefully studying and copying, in masses of colour alone, the best works of art to which they can get access, and applying these arrangements to the particular figures of their patterns.'

LIGHT AND SHADE—TINTING.

In every scene, during the presence of light, some parts fall immediately under the effect of the light, while others are thrown into shade. In art, advantage is taken of this mixture of light and dark parts, not only for the facility with which it enables the draughtsman to separate the parts of a scene, but for the agreeable effects which may be produced by the judicious association and distribution of the light and shade. In the representation of a round object, it is only by a careful disposition of the light upon the convex part, and the truth of the attendant reflected light and shadow, that the appearance of roundness is communicated. The means by which the effect of light and shade is to be produced by tints are now to be described. First, with regard to the preparatory steps in the process.

Provide the best *hard* drawing-paper, which may be had of various size and substance. For subjects in which minute and fine delineation is required, the paper should be smooth on the surface; but when the subject is of a rural character, in which all the shaginess of nature is to be introduced, the paper should be of a rough description, for roughness of surface in such a case will assist in giving truth to the representation. Drawing-papers have frequently a greasiness of surface, which prevents a tint from being spread with evenness; the slightest infusion of gall into the water with which the tint is made will remedy the defect; or the surface of the paper may be sponged with the gall and water before fastening it on the drawing-board.

A few camel-hair pencils must be provided; say two *flat inch tins*, to distribute a tint over a large space; two *swan-quills*, to wash in smaller spaces; and two *hen-quills*, to pick in minute parts. The qualities of these denominations of hair pencils are various. A bad one is far worse than a bad pen; with this it may be possible to write, but with a bad pencil every effort will be foiled. A proof of the quality may be made in the following manner, prior to purchase: When dipped in water, if it spring into a line with the quill, and retain its point, select it; if it spread into two or more points, reject it; and observe that it is not requisite for a pencil to be touched two or three times on the edge of a vessel containing water, nor to be passed between the lips, since these might give a point to a bad one. Provide also a few small delf saucers, in which to mix the tints, and two cups or glasses, to contain water; one to be preserved pure, and the other in which the pencils are to be washed.

The tints may be made according to taste: from Indian-ink, a black; bistre, a brown; or neutral tint, a gray: they are alike capable of communicating smoothness and spirit. With reference to further advancement in the art, it is proper to state that the light and shade of a landscape in the neutral tint is a basis on which the hues of nature in their variety may at a future time be added. The light and shade in bistre is rich in mass, powerful in touch, and susceptible of giving transparency with a high degree of finish.

Fig. 14.

It may be observed, that the relief of an object depends on the just arrangement of the light, the due management of the half-tint and shade, with the proper introduction of the shadow.

Fig. 14 represents three rude stones full in the light, the line A showing the direction in which it falls. The shade-side of two, and the end of the third, show a play of light towards the lower parts, which is to be observed in nature. The shadow is marked stronger beneath, while that which is cast on the inclined stone is strongest at the base of the upright stone, and becomes lighter as it falls on the varying surfaces of the others.

Fig. 15.

Fig. 15 represents an acorn dislodged from its cup. The illumination is from the left, and falls on the rotundity of the acorn, the greatest light being on the most prominent part. In this case a slight portion of half-tint is placed along the upper edge, while the under side gradually approaches through half-tint to shade, and then softens into reflected light on the lower edge, which contributes to the character of smooth roundness, the power of the shadow beneath assisting in giving effect to the object. The light operates in the same

## DRAWING.

manner on the cup, being cast on the advancing part of the hollow; its shade is cast on the receding part opposed to the light, on the same principle that the exterior of the cup is treated, while the shadow relieves the half-tint, as in the previous instance. These plain and circular objects are introduced to call the student's attention to such natural objects, in which it may be there observed how admirably the lights and shades are intermingled with half-tints, so as to obviate all harshness or violent opposition, while the shadows give a due effect, harmonising the whole, and rendering the minutiae worthy of the closest investigation.

Suppose you have made a sketch of such an object, at least six times the size of fig. 14, and that it is fastened down on the drawing-board; a few small saucers, and two vessels containing pure water, on the right hand near the pencils, with the window on the left, so that the sunshine does not fall on the drawing-board: Let a tint be made, according to the previous directions, from either of the cakes before-mentioned, and of any strength the student may think proper. Mix it well with the pencil to be used, and always let that be rather larger than might seem to be required—say, a swan quill. The pencil is properly charged for use when it has been stirred into the tint and gently touched, or passed two or three times on the edge of the saucer. This must be done carefully, because if the pencil contain too much tint, there is a difficulty in spreading it neatly, and the edges will be deficient in softness and delicacy. If the pencil contain too small a quantity, it will be impossible to spread the tint. If the space be large, it will require a little experience to keep the pencil equally charged with the tint.

Whatever may be the tint chosen, it must be washed over all the parts which do not receive the light. Thus with the pencil charged with tint, as before described, commence at the top of the perpendicular stone, fill in the form, and proceed by slow motions downwards, so as to keep the floating or lower edge of the tint constantly being acted upon by the pencil, while it is distributing the tint neatly to the shapes required. The pencil must not be returned to repair omissions, as that would destroy the evenness of tint; the parts should be washed in with correctness at the first. The pencil may then be carried across the shadow to the shade of the flat stone and its shadow on the ground, with attention to the edges; then the upper surface of the diagonally-placed stone, with its shade and shadow. If these spaces be well washed in, they will appear of one uniform power of tint. When it is perfectly dry, strengthen the tint in the saucer by an addition of colour from the cake; this increase of power to the tint must be judged of by experience in its application over the tint first washed in. If the subject be examined, it will appear to consist of three gradations of tint; that which has been spread is the first, as on the upper surface of the diagonally-placed stone; the second gradation of tint appears on all the other shaded parts; and the third gradation is confined to the shadows.

It may be noticed, that if too much colour is added to the first tint, it would produce a harsh effect; and if too little is added, the effect would be deficient: in either case, the due gradation would not be observed. Experiments may be made on a piece of paper, till the proper strength of the tint has been ascertained; it may then be applied to the shades and shadows as before, but omitting the upper surface of the diagonal stone. When this is perfectly dry, the tint must be again strengthened to the third gradation of power, with the same precautions as before; and with it wash in the shadows, keeping the edges of this tint rather within the boundaries of the preceding.

*Mass, Half-Tint, and Shade.*—Suppose such a scene as fig. 11 to have been sketched, and you are disposed to give effect to the outline by a few tints. Consider under what circumstances of light it has been seen in nature, or under what circumstances it might be seen. Imagine it an evening effect, the sun having descended behind the broad mass formed by the castle and trees;

these, on different broken surfaces, constituting the second plan; beyond which is a mid-distance, terminating in water and remote hills; the foreground composed of a rude mass, with rock and bushes interspersed. With this outline you are presumed to be familiar, and will perceive that, by placing the light behind the principal objects, an opposition will be established that must give a character to the whole. Thus the principal will be in half-tint; the light brightest behind the castle, and gradually subdued along the distance; the foreground powerful, so as to relieve the half-tint of the principal, and oppose the distance; thus the gradations or keeping will be preserved, and effect given to the subject.

Attempt the subject, first on a small scale, to become acquainted with the process, and afterwards on one much larger, for improvement. With the first gradation of tint, as in the preceding cases, commence at the top of the tower, and proceed downwards by slow movements, so as to preserve the outline, sweeping the pencil round the masses of foliage, and covering all the second plan; continue the wash over the foreground, except the edge where the pieces of rock are situated; these may be omitted to relieve the mass from the second plan. When the tint is dry, make the second gradation of strength, and wash over again the trees and the ground on which they are situated. Then begin on the left on the foreground, and wash over the mass till within a little of the lights which were left untouched with the first wash. In these lights, and in repetitions of wash towards them, be careful not to let any perpendicular shapes appear; any promiscuous irregularity of form will better express ruggedness of surface. When this is dry, reduce a little of the first tint with water, and wash in the distant hills; then reduce the tint yet more, and with it wash in the space for the sky. As this may represent clouds, an even tint is not of material consequence; the pencil, therefore, should have less tint in it than usual. Begin at the angle on the left hand, and wash over the space, leaving such parts untouched as fancy may select, occasionally touching the extreme point of the pencil in the pure water, so that the tint may become still weaker as it approaches the part just above the castle. If this be well done, whatever may be the forms left untouched in the sky, the appearance will be that of a light or tender tint, getting gradually weaker and softer in a diagonal direction towards the chief light behind the castle.

In this state the drawing would exhibit some effect, and might receive any additional washes or touches that may be suggested by the taste or the judgment of the student. After obtaining a knowledge of the distribution of the tints in their gradations, let the subject be drawn again considerably larger, and now investigate the general principle which regulates the proposed effect, and reflect on each particular part of the process, so as to comprehend the motive for every application of tint. When the tints are washed in, let the drawing be placed at some distance, where it can all be seen at once, without the surrounding objects interfering with the view. At this due removal, which is regulated by the size of the drawing, the gradations of distance and the keeping will more clearly show their correctness or inaccuracy. If the drawing be large, the flat tints on the second plan will tamely express masses of foliage, or the union of many trees; and the castle will require some characteristic markings. The black-lead pencil may be used upon the tint to indicate a variety of form on the building, or to separate the mass into trees of various heights, and these will serve as guides for the introduction of repetition of wash or touch. This proceeding implies finish, and may be carried to the extent dictated by the judgment of the student; but it must ever be borne in mind, that breadth of effect is injured by every addition that disturbs a mass. Variety may be introduced, so as to attack a monotonous space or mass without destroying it. Whenever it appears that more is required to com-

plete the drawing, and the improvement is not suggested by a glance, desist immediately; put the drawing aside, and engage on something else. In a few days, on recurring to the subject, it will be seen with a fresh eye; new ideas will arise; a little will be added, or a little power will be reduced, so as to effect an improvement which no straining of the faculties in the former instance could have produced. A drawing may thus be subjected to frequent revision, and retouched as an advance in taste shall direct.

Suppose such a subject as fig. 10 be sketched, for the purpose of study, in breadth of light, the opposite of the last effect: let a tint be made less powerful than the first gradation—such a tint as might represent clouds that were not gloomy—and with it wash over the space for the sky, preserving the forms of the trees, and softening off the tint in a diagonal direction, so as to leave the light along the horizon, with the greatest breadth on the right. When dry, repeat a few washes on the angle towards the left and along the top, so as to produce a gradation of power from the top to the horizon, and it will give the effect of retiring or keeping. If the tint has not been washed in with evenness, endeavour to convert any conspicuous form into a cloud, by picking or filling in on its edges a corresponding tint, so as to make it form part of another more appropriate shape. Then with that power of tint, considered as the first gradation, commence at a part not so high as the gable of the cottage, upon the trees, with an irregular form, distinct from a straight line, and continue the tint over the trees beneath, to the line of ground on which the cottage stands. Begin again at the lower part of the base beneath the cottage, and wash in the tint up to where the ground-line before-mentioned joins the boundary of the subject, and continue to wash in the tint, in agreement with the form of an indicated path to the cottage door, and so across to the mass of foreground and bush on the right. When all is perfectly dry, make the second gradation of power in tint, and wash over the lower portion of the trees close to the cottage, with the space before washed in, observing not to let it approach the edges of the previously-washed tint, lest the shapes should appear harsh, particularly on the bush opposed to the light horizon. It must be observed, that the power which was required to separate masses in outline, ceases to be proper on the application of tint, as there is no decided outline in nature. With the tint of the second gradation, wash in the door, the window, the shade of the roof with its shadow, and the shade side of the chimney. Then with the third gradation of power, wash in the foreground and the lower part of the bush, with the precautions before-mentioned. When dry, place the drawing at a due distance, according to its size; and observe, if the effect be that of a cottage in a mass of light, that the gable end cannot properly receive the same degree of illumination as the roof and the side where the window is; it will therefore be proper to wash over it a tint that will keep it in its place. You must reflect, that as the light is concentrated by the illumination from the right being poured upon the cottage, its relieving mass of half-tint will be lighter than on other occasions; therefore a tint lighter than the clouds will be sufficient to detach it from the brighter side, without destroying the mass of light in which the cottage is placed. As in the case of the preceding subject, any repetition of wash or touch that may seem to be required should be added, being careful to preserve the intended effect. A little practice will teach that the trees should be diversified with tender tints, so as not to destroy the mass of light; that the distant sea should be washed with a tint to relieve it from the horizon; that the ground on which the cottage stands may be broken or enriched with characteristic forms; and that the foreground may be touched with a power that shall judiciously detach it from the second plan.

In the examination of drawings, during the progress of retouching, if a part appear too light, or another part too dark, so as to produce the effect of *spottiness*, cover

such part with the fingers, and imagine the appearance with any proposed alteration: if an improvement be suggested, at once adopt it, and examine again; always paying attention to preservation of the masses, on which both simplicity and effect depend. A drawing should be ascertained to have *one principal light*, while the subordinate lights diminish in brilliancy in proportion as they are removed from the principal. Masses of shade should increase in power of tint conformable to their degrees of remoteness. These are essential to keeping and effect. Making-out or marking more than the respective distances require, touches which are inappropriate, or harshness of any description, are all departures from the principles of the art, and deviations from natural appearances. Although effects may be observed in nature at variance with these rules—such, for instance, as light scattered equally on the foreground and the mid-distance, or the whole scene being beneath a glare of sunshine, or in shade by the clouded state of the atmosphere—yet these are effects unsuited for pictorial delineation, because they are deficient in what constitutes beauty and attraction in the art.

You may have observed how essential a sky is in giving effect to a drawing. The great variety of forms, lights, half-tints, and shades—the storm, the distant falling shower, and other incidental effects, which the atmosphere presents to the view, should always be regarded with attention, not only because advantage may be taken of such diversity for powerful contrast, but because a well-arranged sky is a beautiful portion of a landscape. The repetition of tender washes over each other may be justified only in the endeavour to obtain that tenderness and delicacy of tints which are conducive to faithful representation of clouds; for continuing to wash the same tint in successive applications will produce an effect that is termed *woolly*, from its being deficient in that *sharpness* or spirit which is obtained by a few decided tints applied in just gradations. These varieties may be adapted to the nature of the scene, and may, by their judicious contrasts of form and tint, contribute very materially to the general effect of a subject—as in a stormy sky, bright horizons, and beams of light. The effect of moonlight may readily be given by strong tints, softened off in the circular direction of the moon, and repeated till the gradation is obtained; then give a wash over the whole sky. *Take out* the clouds to a half-tint by dabbing, and *take out* the moon to the clean paper with crumbs of bread. A few catching lights on the clouds near the moon may be *taken out*, but made less bright than the moon.

#### HUMAN FIGURES.

A knowledge of drawing the human figure is to be gained by a careful study of the outlines of the different parts composing the trunk, limbs, and members. All such integral portions of the human figure, if time and other circumstances permit, may be first studied from casts conveniently placed on the table, so as to give a facility to the hand in this department of sketching.\* It must, however, be borne in mind, that exercises of this nature, under the guidance of a master, do not obviate the necessity for studying the human figure from life; neither do they supersede the acquisition of a knowledge of figure-drawing on a small scale, for the purpose of ornamenting and giving effect to a scene from nature. The introduction of human figures is of considerable utility in drawing a landscape, in order to serve as a scale by which a spectator may know the probable measurements of objects near which the figures are situated; figures also give animation to a scene, and, by the touches of light or of dark which they justifiably offer, communicate valuable relief to a mass, or assist in the keeping of the subject.

There are several well-known rules with respect to the drawing of human figures; they are as follows:—

\* Stucco casts of figures, and their subordinate parts, may be had from different manufacturers of models of this description in London, Edinburgh, and other large towns.

## DRAWING.

The height of a figure should be eight times that of its head; half its height is at the lower part of the body; a quarter of its height is at the knee. This division of the human figure can readily be put on the memory by

Fig. 16.

the following method:—Draw a perpendicular line, then divide it into eight equal parts; give one for the head, and, placing dots at each part in succession, give a second part for the breast, a third part for the centre of the abdomen, a fourth part for the lower portion of the body, a fifth part for the midway of the thigh, a sixth part just beneath the knee, a seventh part just beneath the calf of the leg, and the eighth part to the sole of the foot. The shoulders are two heads in width; the elbow is a head and a-half from the shoulder; and the arm, with straightened fingers, is three heads and a-half from the shoulder; that is, the fingers will reach down to the fifth division of the perpendicular. The measurements of the human figure, according to the highest standards of art, are exceedingly minute; but such are not necessary where a mere sketch of the form is required to enliven a landscape.

Fig. 17.

Fig. 17 exhibits the mode of ascertaining the heights of figures, wherever they may be placed in a scene, according to the rules of perspective. A is a figure on the base line; the eyes determine the height of the horizontal line H. Draw the visual rays from the head and feet of the figure A to the point of sight P, and the receding diminutions are determined, supposing the space to be a level surface. Where the situation of a figure is below the visual rays, as B, draw a parallel line from the feet of the figure towards the ray, and raise the perpendicular line B. Now, the measurement between the visual rays at B is the height of the figure required. When the situations of figures are above the rays, as at C and D, draw the parallels and the perpendiculars to their intersections beneath the elevations, and the measurements between the visual rays

at C and D will give the respective heights of the figures required. The figure E being on a level with the base, a parallel line drawn from the lower ray will determine the height of a figure so situated.

**ARRANGEMENT AND EFFECT.**—It may be proper to state that, in selecting scenes from nature, the expanse of vision, or 60 degrees, will often include more of the scenery surrounding an object than is required. On such occasions the boundary lines may be placed at pleasure, or so as to give the best effect to the principal. When a more expansive view is required to be taken than is contained within 60 degrees, the station becomes a pivot from which a succession of sketches, each 60 degrees of expanse, are to be taken. Thus any portion, or the whole circle, may be completed, forming what is termed a Panorama; always remembering that the points of sight and vanishing points are on the same horizontal line. Foregrounds may be added at pleasure; yet they should be consistent with the scene, and such as might have been on the spot. A foreground must ever be more or less imaginary, because the space between the objects which compose the scene and the spectator cannot be otherwise filled up. A human figure, should there be one very near, would appear as high as the horizontal line, and the lower extremities would be hidden: such unseemly representations are avoided, by supposing that the scene is viewed through a cavity in the side of a room, or a frame, which is the plane of the picture.

Large drawings require a bold treatment suited to the distance whence they are to be viewed, but the dimensions of a drawing give it no additional claim to notice. The situation in which a drawing is seen to the greatest advantage is when its horizontal line is immediately in front of the spectator's eye, and at such a distance that the whole can be seen without requiring the head to be moved. The beauty of linear perspective, more particularly in complicated architectural subjects, can only be seen to perfection from one point, and that is through an aperture immediately in front of the point of sight. The eye being placed close to an opening, in a card, for instance, and at such a distance as to embrace the whole subject, every line then becomes adjusted to the vision, and the diminution of surface in the drawing contributes to the truth of the effect, according to the appearances in nature.

Representations of landscape scenery have for many years been made by mechanical means, with the aid of the *camera lucida*, a species of box provided with a mirror and lens, in which the representations fall, and are therefrom copied by an attending artist into his sketch-book. The idea of fixing representations of this nature on the surface on which they fall, by some chemical process, so as to save the trouble of copying, appears to have been entertained by ingenious men both in France and England; and at length the possibility of doing so was made known at Paris in the month of January 1839. The discoverer was M. Daguerre, aided, however, by one or two other

persons; and he was rewarded by the French government for making known the process which he pursued in the art, which was henceforth called Daguerreotype, or as frequently Photography (that is, drawing by the action of light). Since Daguerre's invention, various improvements and new discoveries have been made in the art of photography—all of which, as belonging more to mechanical and chemical than to imitative art, will be treated in a subsequent number. Some parties no doubt make use of these photographs in the composition of their pictures; but such a practice is more than questionable—it is simply copying in the worst sense of the term, and not trusting to that higher power of tracing and imitating external forms which must ever distinguish the legitimate artist from the empiric and pretender.

## PAINTING AND SCULPTURE.

Drawing with black-lead pencils, chalk, or crayons, and Indian ink, constitute the first steps in a study of the fine arts. The more advanced studies refer to drawing in water-colours, paintings in oil-colours, and sculpture—three separate branches, individually followed as professions. It is not our intention to offer any instructions in these advanced departments of art, but to say only a few words as to the manner in which they are performed, and the advantages derivable from a contemplation of their varied products.

Drawings in water-colours are executed on thick hard paper, the outlines being lightly sketched with black-lead pencil. The colours are prepared in small oblong cakes; when required, a portion is rubbed down with water in a small saucer, and applied with a camel-hair pencil. Great care is necessary in laying on the respective colours; for the nature of the material wrought upon, and the transparency of the tints, prevent that freedom in rubbing out or obliterating one colour by another, which may be resorted to in oil-painting. For directions how to proceed, we refer to a small and accessible work on Water-Colour Drawing, by Mr John Clark. (W. S. Orr & Co., London.)

Oil-paintings are executed on a variety of materials, but chiefly canvas, stretched on a frame; less frequently on wood, copper, and slate. The canvas or other material requires to be prepared with a coat of paint, to give it a smooth surface, and to prevent the absorption of the colours afterwards laid on. The colours are ground and prepared with fine nut, poppy, or linseed-oil, and are ordinarily purchased by painters in bladder-bags, in a state ready for use. For convenience in using, a small portion of each colour required in the piece is placed on a thin oval board called a *palette*, which is held in the left hand, by passing the thumb through a hole at one extremity; the canvas frame is generally placed on a stand called an *easel*, in front of the artist, and the colours are applied with brushes of fine elastic hair. The colours being opaque, the painter has the opportunity of retouching his work, by putting one colour over another, when the previous colour has been thoroughly dried. Oil-paintings are sometimes executed on walls and the roofs of buildings; but paintings of water-colours on walls are the most ancient. These, known by the name of *fresco*-painting, are done while the surface of the plaster is moist, and admit of no retouching when the plaster dries. Specimens of *fresco*-painting have been found in Herculaneum and Egypt; still, after thousands of years, maintaining their brilliant colouring.

The greater number of sculptures, ancient and modern, are executed in single blocks of white marble; a few are in bronze. A sculptor commences by drawing his design on paper; when satisfied with this, he proceeds to form a model of his proposed figure in moist clay, supporting it partly by irons and framework. Having, as he thinks, brought his model to perfection as respects attitude and surface, it is ready to form a copy to work from; but as it is a perishable material, he takes a cast from it in plaster, and this cast serves as a mould for a fac-simile model in plaster of Paris. The plaster cast being hard and durable, it is used as the permanent copy by the different workmen. The first operative employed on it, by means of a machine, takes off the rougher parts of the marble, and gradually diminishes the block in the required directions. The next is an able assistant, who brings the figure still nearer in form to the copy; and it lastly passes under the hands of the sculptor, who gives that tasteful finish and spirit which the nature of the subject requires. Statues in bronze are cast in moulds taken from finished models.

With respect to the advantages derivable from a contemplation of the higher objects of art, they may be defined as the education of the eye and of taste, which is of particular importance to the draughtsman.

Addressing ourselves again to the pupil—you will

observe that nature, though truthful, is not always consistently beautiful or graceful. We see living human figures less or more deformed, some tall and slender, others short and ungainly, and a third class out of proportion in the different parts of their person. Now to set about copying figures possessing any of these defects would be absurd; and you must in all cases endeavour to imitate only what is allowed to be nearest to perfection. Taking mankind in the gross, exceedingly few individuals come up to anything like a perfect standard. Fashions of dressing and habits of living, independently of original defects of form, conspire to throw the figure out of just proportion; so that a perfect man or woman, as respects bodily form and carriage, is practically out of the reach of all ordinary students. In London and elsewhere there are *life* academies, in which draughtsmen study from the best-formed living figures that can be hired to exhibit themselves; and studies of this kind are indispensable for all who design following out the higher walks of art. Studies from sculptured figures are nevertheless desirable, because these are formed upon the highest ideality of grace, beauty, and perfection; and a contemplation of their exquisite proportions is believed to refine and discipline the tastes of the student. It is on this account that we append the present observations on this branch of the art.

The figures which afford a recognised standard of perfection, are for the most part works of ancient Grecian art. The period in which the highest conceptions of personal perfection were formed, was during the administration of Pericles (about 440 years before the Christian era). In this age flourished Phidias, the greatest sculptor of ancient or modern times, who raised art from a comparatively rude to a very high condition. With him commenced what is called the *ideal style* of sculpture, in other words, a style aiming at an exalted conception of simple truth and grace. The religion of the Greeks, which was the idolising of deified heroes and heroines, offered the utmost scope for these lofty conceptions. His masterpieces were the figures of Pallas Athene and Jupiter, his Venus Urania, his Nemesis in the temple at Marathon, and his Amazon. He

Apollo Belvidere.

taught a number of others, among whom Alcamenes of Attica, and Agoracrites of Paros, were his favourite pupils. Both these sculptors executed several works which attained a high reputation. A contemporary was the famed Myron of Eleutheris in Bœotia, who represented highly-finished athletic forms. His Runner, his Slinger, and his Pancratiasts, are celebrated. His

## PAINTING AND SCULPTURE.

ideal of Hercules completed this class of forms. His Heifer and his Sea-Monster are famous among his animal forms. But one thing was wanting to this great sculptor—grace of expression; in this he was surpassed by a rival sculptor, who adopted the undulating line of beauty, and first expressed the sinews and veins with accuracy. He created the ideal of Apollo in the position of an archer, who has just shot the serpent Python—the figure indicating in its expression a placid satisfaction and assurance of victory. This splendid work of art was found at Antium, the modern Capo d'Anzo, at the end of the fifteenth century. It was purchased by Pope Julius II., then a cardinal, and placed in that part of the Vatican called the Belvidere, whence it has been commonly named the Apollo Belvidere. The fore part of the right arm and the left hand, which had been destroyed, were restored by Angelo du Montorsoli, a pupil of Michael Angelo. The ease of the attitude and excellent proportions of the figure are universally admired. Our small outline engraving affords but an imperfect idea of the majestic original.

After the ideal style of Phidias and his disciples, succeeded the period in Grecian art distinguished for the beautiful. Praxiteles and Scopas were the great leaders of this improved style, in which beauty was united with grace. The most celebrated works of Scopas are his furious Bacchante—the head bending backwards, uniting the highest beauty with Bacchalian frenzy; his Cupid, his Venus, and his Achilles, who is placed in a mournful attitude, contemplating as if lamenting the loss of his friend Patroclus. Praxiteles, the most feeling of all sculptors, created the perfect ideals of Diana and of Bacchus; the latter being designed by him as a contrast to the Satyrs and Fauns, whose figures express rudeness and licentiousness. The figure of Bacchus was soft and tender, without being effeminate, and expressed perpetual gaiety and sport. He effected also the admired statue of a Satyr, and the ideal of Eros, or Cupid, which was that of a playful boy. Praxiteles was the first to represent Venus entirely naked, thus giving to the world a new ideal of the goddess. His most celebrated works are his Venus of Cos and of Cnidos; the former covered from the hip downwards, the latter entirely naked, holding her garment with her left hand over the bath. The group of Niobe is also ascribed to this master.

Achilles.

Venus de Medicis.

To the epoch which followed that of Praxiteles is usually ascribed the statue of Venus, styled the Venus de Medicis, from having been placed in the gallery of the Medici at Florence, after its discovery at Tivoli in 1695. It is of pure white marble, and measures, ac-

ording to one authority, 4 feet 11 inches, and according to another, 5 feet 2 inches, in stature. Some small portions have been restored. It is not ascertained who was the sculptor of this exquisitely-designed figure. The pedestal exhibits the name of Cleomenes; but the inscription is modern. It has been the object of the artist to represent Venus either as just coming from the bath, on the point of dressing herself, taken by surprise, and full of modesty, or as appearing before Paris for his judgment in the contest with Juno and Minerva for the prize of beauty. By many the countenance is thought unintellectual, or at least unexpressive. The graceful waving lines of the body have never been surpassed; and, taken in different points of view, they offer a most advantageous study for ideal grace and beauty.

In this latter age appeared Lysippus of Sicyon, Euthykrates, Apollodoros, and others, among whom stand pre-eminent Polydorus, father and sons, of Rhodes, who formed the celebrated group of Laocoon. A number of great works of this era were executed by Greek sculptors at Rome, to whom we are indebted for many busts of distinguished Romans.

Among the numerous ancient sculptures, which, like those already mentioned, have survived until modern times, and been preserved in museums, may be mentioned the following as useful studies:—The Dying Gladiator, a naked manly figure, reclining on his shield, his weapon broken, and expiring from a mortal wound in the side: The Three Graces, a group of female figures in different attitudes, calculated to show the symmetry of the form in various positions: Antinous, the figure of a graceful youth, in a simple attitude, expressive of melancholy, and executed with great correctness of proportion: Adonis, a figure somewhat more slender and elegant: Venus Genetrix, a figure draped, and possessing a noble simplicity of expression; the drapery hanging in the most elegant folds, is in itself a study: Cleopatra meditating in a reclining position: Laocoon, a group of figures above referred to, consisting of a father and his two sons, struggling in the folds of serpents, and strongly characteristic of the distraction and suffering which may be conceived to be endured in that dreadful situation: Hercules, a figure expressive of robust muscular strength.

After a lapse of nearly ten centuries, the art of sculpture was revived in Italy, and thence spread to France and other modern nations. Germany has latterly produced various sculptors of eminence; among these may be mentioned Dannecker of Stuttgart, and Tieck of Berlin. Dannecker has executed, in pure white marble, a figure of Ariadne seated on a tigress, in an attitude of inexpressible elegance, and equal to the works of ancient art. It is contained in a private museum at Frankfort-on-the-Maine. Thorwaldsen, a Danish sculptor, has likewise produced several works of striking grandeur and beauty; not the least imposing of his designs is the colossal figure of a lion carved in the solid rock at Lucerne in Switzerland. The animal is supposed to be dying from the effects of a wound from a spear, and reclining over a shield emblazoned with *Neus de Vis*: it is a monument emblematic of the fidelity of the Swiss Guards who perished in defending their master Louis XVI., on the 10th of August 1792, from the brutality of the Parisian mob.

Canova, an Italian (born 1757, died 1822), has been justly esteemed the restorer of the graceful and lovely in sculpture. All his works display a surprising degree of softness and delicacy, and will form admirable studies to the young artist. His Cupid; Psyche, standing half-dressed, with a butterfly; the repentant Magdalene; Hebe, smiling and animated; a Venus, partially draped; Benevolence (several figures); Graces rising from the bath—are only a few of the works by which Canova gained his great reputation. Modern sculpture has likewise been distinguished by various works executed in England by Flaxman, Chantrey, Westmacott, Baily, and others. Modern art has almost reached the ancient in the figure of Eve at the Fountain, which is conceived

in a style of pure simplicity and grace, with somewhat more intellectuality in the features than is generally to be found in the Grecian sculpture of female figures.

Eve at the Fountain.

Besides studying the manifold graces of ancient and modern sculpture, with the view of improving the taste in reference to figures, you are recommended to study the styles and compositions of the more celebrated painters, as nothing could be more suitable for imparting correct ideas respecting drawing, disposal of groups of objects, and colouring. Another great benefit will consist in making you feel your own deficiency, and how much you require to attain by diligent study. Painting, you will learn, has, since the revival of art, taken the character of *schools*, or peculiar styles, each of which has had its leaders and followers; for example, there is the Florentine school, commenced by Michael Angelo Buonarrotti (born 1474, died 1564), who delighted in representations of the grand and terrible. The Roman school, of whom Raphael (1483-1520) was the head. The great characteristics of this school are, truthful representations of nature, a just expression of the passions, a chaste nobleness of design, and correctness of drawing. The Venetian school, headed by Titian (1477-1576), the characteristics of which were the harmony of colours, delicacy of tints, and a judicious contrast of light and shade. This school was improved by Corregio and Tintoretto. The German school, led by Albert Durer (1471-1528) and Holbein. The second Lombard school, distinguished by the works of the three Caracci (1555-1609). The French school, founded by Nicholas Poussin (1594-1665), Vouet, and Charles Le Brun. The Flemish school was founded by Peter Paul Rubens (1577-1640), whose design is dignified, his drawing of anatomy and perspective correct, and his colouring brilliant. The only objection to some of his figures is, that they are too heavy; and certainly they want the grace of those of Raphael. The Dutch school, of which the most prominent painter is Rembrandt (1606-1668), is less distinguished for taste than the faithful adherence to nature.

The works of the eminent masters in these various schools were chiefly scriptural and historical; and scenes of a miscellaneous kind, embracing landscapes, figures, animals, sea-pieces, architecture, and other subjects, were painted by contemporary artists, who followed no particular school. Among these great masters may be named Claude Gelee of Lorraine (1600-1682), whose landscapes are exceedingly beautiful, his colouring delicate, his tints tender, and his lights and shades unrivalled; Salvator Rosa (1615-1673), whose taste was for the wild, rugged, and romantic aspects of nature; Gaspar Poussin (1613-1675), whose pictures are grand and remarkably true to nature. The sixteenth and seventeenth centuries produced the following masters, all of whose works are esteemed:—Paul Veronese, Guido, Carlo Muratti, and Spagniolletto—historical; Murillo (Spanish)—figures; Hobbima—landscape; Canaletti—buildings; and De Witt—the interiors of churches. Vernet, a Frenchman of the

eighteenth century, was celebrated for his sea-pieces and figures. In the course of the seventeenth century, Holland produced, but cannot be said to have encouraged, many distinguished painters. Among these are included David Teniers, celebrated for his representations of domestic and familiar scenes: Paul Potter, renowned for his cattle pieces, the most remarkable of which is his picture of a bull; it is contained in the Royal Museum at the Hague, and valued at £5000: Philip Wouvermans, noted for his landscapes, beautiful skies, and scenes with groups of figures hunting, or otherwise engaged in field-sports: Berghem, also noted for his landscapes, his foliage, cattle finely drawn and coloured; the woodland scenes of this painter are exquisitely finished and true to nature: Vandervelde, a painter of naval victories and sea-pieces, all remarkable for richness of composition and effect: Gerard Douw, like Teniers, famed for his domestic scenes. Jacob Ruysdael, who painted in the style of Berghem, but gained great celebrity for his representations of water.

All the eminent works of art, whether in sculpture or painting, are now contained in a few great national museums, or in the private collections of men of taste or opulence. The principal museums are those of the Vatican at Rome, the Gallery of the Medici at Florence, the royal galleries at Munich (now the head school of painting and other fine arts in Germany), the Louvre at Paris, the British Museum and National Gallery in London, and the Royal Museum at the Hague. If at all within the means of young men desirous of pursuing professions in which taste in drawing is requisite, we strongly recommend them to visit the Museum of the Louvre, which is rich in ancient sculpture and modern paintings: the sight of the many fine works of art in Paris would scarcely fail to inspire a high degree of refined taste. If unable to accomplish this desirable object, we advise you to pay occasional visits to any private collection to which you can gain admission, and also to exhibitions and museums open to the public. Among recent works of English art generally accessible, the historical pieces of Haydon and Hilton, the historical and pathetic pieces of Allan, the grand architectural idealities of Martin, the church and other architecture of Roberts, the landscapes of Gainsborough, Calcott, Mulready, Thomson, and the Naemyths, the animals of Landseer, the sea-views of Stanfield, Turner, and Williams, and the faithful delineations of humble life by Wilkie, and many other works of art which might be mentioned, will afford much pure pleasure and instruction, and show what can be accomplished by a cultivated observation, and a persevering desire to excel.

In the course of your observations you will learn, that in the delineation of human figures great care requires to be paid to historical costume and the fashion of artificial objects represented. A person who lived in the eighteenth century, for instance, should not be dressed as an ancient Roman; nor should the interior of a house of the fifteenth be decorated like one of the sixteenth century. On this account every student of the fine arts requires to be well instructed in history, archaeology, and other branches of learning. With respect to statues, it is so important to give an easy and graceful effect, that a departure from exact costume is allowable, so far as to place a loose garment over or about the person. A due perception of the beautiful and truthful in pictorial delineation must, however, be in all cases a work of time. At first, the unpractised eye, or, properly speaking, the untutored mind, will perhaps be most charmed with a gaudy daub, and see in the finest work of art only a dull and valueless scene. But the repeated contemplation of pictures, the comparison of one with another, and the constant reference to actual nature, will remove such impressions; and the work of true merit standing apparent, will receive the highest need of approbation.

The last advice we have to give is, put away all envy of the progress of others, and be above those mean jealousies which too often impair the character of the artist.

## GYMNASTICS—OUT-OF-DOOR RECREATIONS.

A DESIRE for indulging in active sports and exercises has evidently been given to youth for the admirable purpose of promoting bodily health and strength, at a period of life when mental occupation or sedentary employment would not only have been unfitting, but positively injurious. Instead, therefore, of railing at the boisterous pastimes of boyhood, ridiculous as they may sometimes appear, we ought to view them, so long as kept within the bounds of moderation, as consistent with a great providential design in creation, and worthy of our warmest approval and encouragement. Impressed with these considerations of the value of youthful recreations, particularly those carried on in the open air, we should by all means afford reasonable scope for all the usual and harmless sports in which young persons are pleased to indulge; we should say to parents, let the boy have his marbles, ball, nine-pins, and bat; and the girl her doll, skipping-rope, and hoop, besides any other toys which would call their respective faculties into harmonious exercise. But an indulgence in physical recreations and general amusements is not to terminate with the period of youth. In advanced and middle life, it is of the greatest importance to health to relieve the tasked brain, to soothe and compensate the drudgery of our current labours, and to bring into exercise those parts of our muscular frame and intellect which professional duty has left unoccupied. To young men, especially, whose frame requires regular and bracing exercise, those out-of-door recreations which afford a certain degree of amusement are indispensable; and to them the contents of the present sheet are more particularly submitted. Our endeavour will be to point out what sports may with propriety be indulged in, suitable to the different seasons of the year, and how they may be pursued with advantage to health and other circumstances.

### GYMNASTIC EXERCISES.

Gymnastics are those exercises of the body and limbs which tend to invigorate and develop their powers.\* In an ordinary course of living, without due regard to rules for promoting bodily strength, the frame becomes relaxed, the muscles are soft, the circulation of the blood languid, the bones and joints debilitated, and the stomach weakened and dainty. To avert, as far as possible, these imperfections, gymnastics ought to form a part of education in youth, when the joints and muscles are flexible, and time is permitted for the various kinds of exercises. 'To be largely useful to the wellbeing of the economy,' says Dr Robertson, 'the exercise must not be confined to any set or series of muscular movements; out, as far as possible, should bring into play all the moving powers of the body. It may be said, in general terms, that the greater the number of muscles concerned in the exercise, and the more completely it involves the full contraction of each muscle, the more influential will the exercise be.'

*Precaution.*—It has not been unusual of late years to conduct the gymnastics of schools on an improper scale, by impelling young persons of comparatively feeble frames to undertake feats and exercises which are been at variance with the bodily organisation, or at least highly dangerous, and of no practical value. A

\* The term *gymnastic* is from a Greek word signifying *naked*, as athletes or young persons who practised bodily exercises in the public arena or gymnasium of ancient Greece, being, for freedom of motion, nearly in a state of nudity. The more gentle kind of gymnastics for females are termed *calisthenics*, from words signifying elegant or graceful exercises.

caution is necessary on this subject. 'The best guide we can have,' observes Dr Andrew Combe, in his work on *Physiology*, 'is to follow the footsteps of nature, whether it is in harmony with the mode of action assigned by the Creator to the parts which are to perform it. If it be so, we may proceed with perfect confidence that it will not only improve the health, but add to the freedom, elegance, precision, and strength of our movements; whereas, if it be opposed to the obvious intention of the Creator, we may rest assured that no good can accrue from it. If, for example, we examine the various attitudes and motions of the body which occur in fencing, dancing, swimming, shuttlecock playing, and some of the better class of gymnastic exercises, we find that they are not less graceful and beneficial to the young who engage in them, than pleasing to those by whom they are witnessed—just because they are in perfect harmony with nature, or, in other words, with the structure and mode of action of the joints, ligaments, and muscles by which they are executed. But it is far otherwise with some of the anomalous exercises which were at one time so fashionable, and which are not yet extinct in schools and gymnasia, and which seem to have for their chief object the conversion of future men and women into foresters, firemen, or savages, rather than into beings who are to continue to have the use of stairs, ladders, carriages, steamboats, and the other conveniences of civilised life. It is no doubt a good thing for a boy to be able to climb up a perpendicular pole or a slippery rope, when no other means present themselves of attaining an important object at its upper end; and it is an equally good thing for a young lady to be able to sustain her own weight hanging by one or both hands, when there is no possibility of resting her feet on terra firma; and where boys and girls are strong enough to take pleasure in such amusements, there is no great reason to hinder them, provided they are impelled to them, not by emulation or any secondary motive which may lead to over-exertion, but by the pure love of the exercise itself. In all ordinary circumstances, those only who are vigorously constituted will attempt them, and if left to themselves, will be sure to desist before any harm can be done. But the case is entirely altered when such extraordinary evolutions are not only encouraged, but taught to all indiscriminately, whether they are strong or weak, resolute or timid. We have only to reflect for a moment on the structure of the shoulder joint, and on the sphere of action of the muscles surrounding it, to perceive at once that the position of the one and the strain upon the other, caused by the exercises alluded to, are so forced and unnatural as to exclude the possibility of the Creator having intended either to be practised except upon occasions of urgent necessity, and to discover how preposterous it is therefore to make them a subject of general instruction. Nay, the very violence of the effort required to sustain the body when hanging by the hands, is far beyond that moderate exertion which adds to nutrition and to strength; and in delicate subjects it may even induce relaxation and stretching of the ligaments and blood-vessels, and thus, as in the case of the young men at Cambridge, lay the foundation for future and fatal disease. The same remarks apply to a common practice of making the pupils slide down an inclined plane resting on the hands alone, by which unnatural effort the shoulders are pushed half way up the neck, and the wrists, arms, and chest severely tried. But in these and other similar evolutions, it requires only to look at the dragging and distortion which they produce, and which form such a painful contrast to the ease and

grace of all natural motions and attitudes, to perceive that they are out of the order of nature, and that neither health nor elegance can result from them. In the selection of exercises for the young, then, we should not be misled by a vain desire of surmounting difficulties and performing feats at the serious risk of inducing aneurism or rupture, but rather endeavour to strengthen the body by active amusements, which shall call the social and moral feelings and intellect into play at the same time, and by the practice of such gymnastic evolutions only as tend to improve and give tone to the natural action of the moving powers. And in endeavouring to attain this object, we should be always careful to avoid great fatigue, and to modify the kind, degree, and duration of the exercise, so as to produce the desired results of increased nutrition and strength; and to remember that the point at which these results are to be obtained, is not the same in any two individuals, and can be discovered only by experience and careful observation.' With the precautions suggested by these observations, the following gymnastic exercises may be pursued:—

General Directions.

The exercises are best performed in an open court or piece of ground, firm below, but without any stones to injure the feet or person; a grass plot is the most suitable. The fittings are a climbing stand, vaulting bar, leaping poles, &c. The dress of the gymnast is to consist of easy-fitting trousers, and encircled with a belt or girth. The belt should pass round the loins, and not be too tight. The performances should be in the forenoon, or at least before any heavy meal.

Positions and Motions.

The body must be drilled in the art of standing and throwing out the limbs. In standing properly, the person should be erect, the head held up, and the face looking straight forward; the shoulders are to be square, with the chest fully exposed, so as slightly to curve the back; the legs closed; the heels in a line, and closed; the toes turned out; the arms hanging straight down; the elbows held in to the body; the hands open to the front; the little finger touching the legs; and the thumb flat to the forefinger. When perfected in the art of standing in this position, which is called attention, as shown in fig. 1., the next thing is to be taught to march or walk, as in the case of a soldier on drill, the feet being alternately thrown out, and both brought together into position, at the order to halt.

The pupil next learns to bend the body and extend the arms. The first exercise of this kind is to carry the hands to the front, the fingers lightly touching at the points; now raise the arms, the hands still together, till they are held over the head, as in fig. 2.

The second motion is to learn to hold the arms out in front, the tips of the fingers touching, and returning to the position of fig. 1: this is to be done repeatedly. The third is to extend the hands separately, and raise them over the respective shoulders, the fingers pointing upwards. The fourth motion is to keep the arms and legs straight, and to bend the body forward, with the head down, and the tips of the fingers towards the ground. This somewhat difficult motion is represented in fig. 3.

A fifth motion is to resume the position of attention, allowing the arms to fall freely to their place, but still without bending the legs. These motions are trying to the pupil, and should be done

gradually; the great object is to exercise the muscles bit by bit, and perfection is not desirable at first. Then follow other motions—as throwing the arms horizontally out in opposite directions, swinging the arms, stretching them to the full extent forward, while the palms are in contact, doubling the arms up so as to make the tips of the fingers rest on the shoulders, making the palms come fully in contact while the arms are thrown behind back, &c. In these, it is of importance to exercise the left hand and arm fully more than the right, in order to make them equally active and strong.

Indian Club Exercises.

The pupil having advanced in simple personal exercises, is supposed to be somewhat strengthened; and to further the operation, he proceeds to the Indian club exercise. The main object is to expand the chest, and increase the power of the arms. For this end some sedentary persons regularly exercise themselves with dumb-bells; that is, heavy pieces of metal, one being held in each hand. The club exercise is an improvement on that of the dumb-bells. The club bears a resemblance to the bat for cricket, and varies in weight from two to twelve pounds. One is used in each hand. The following, according to Torrens, are the regulation-exercises now adopted in the army:—

'The recruit being placed in the position of attention, with a club in each hand pointing downwards, as in fig. 4, must be exercised as follows:—

*First Part*.—1. At the word *one*, the club in the right hand is slowly carried round the head, until the hand arrives in a perpendicular line above the shoulder, with the large end of the club pointing in a diagonal direction to the rear; 2. The club in the left hand is raised in a similar manner, and carried over that in the right hand till it reaches a corresponding position; 3. The hands are carried slowly to the right and left, until they become in a true horizontal line with the shoulders, the large ends of the clubs still remaining to the rear; 4. The hands are brought slowly to the first position. Care must be taken that the recruit does not stand with a hollow back during this and the succeeding practice.

*Second Part*.—1. Raise both hands to the front, approaching them close together, in horizontal line with the shoulders, the clubs being held perpendicular, with the large ends upwards; 2. With the body well poised forward, separate the hands, and carry them to the right and left line with the shoulders, the large ends of the clubs remaining upwards; 3. With the head well kept up, let the clubs turn over till they point in a diagonal direction to the rear, the hands still remaining out in a line with the shoulders; 4. With the arms extended, drop them slowly to the first position.

*Third Part*.—1. The club in the right hand is circled round upon the right of the body for a few revolutions of the circle, or until the word *halt* is given; 2. The one in the left hand is used in the same manner on the left of the body, until the word *halt* is given, when the recruit will remain perfectly steady in the first position; 3. With the body rather leaning forward, circle both clubs at the same time, on the right and left of the body, until ordered to halt.'

Leaping—Vaulting.

The simplest kind of leaping is that of jumping on level ground from one point to another, with or without a run. The run accumulates power in the person, or momentum, and enables a person to leap considerably farther than without such an aid. 'In all kinds of

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 4.

Fig. 5.

## GYMNASTICS.

leaping,' observes Walker in his 'Manly Exercises,' 'it is of great importance to draw in and retain the breath at the moment of the greatest effort, as it gives the chest more solidity to support the rest of the members, impels the blood into the muscular parts, and increases their strength. The hands, also, should be shut, and the arms pendent. The extent of the leap in height, or horizontally, is proportioned to the power employed and the practice acquired. As it is performed with facility only in proportion to the strength exerted, and the elasticity and suppleness of the articulations and muscles of the lower extremities, much exercise is necessary to attain that degree of perfection which lessens all obstacles, and supplies the means of clearing them without danger. Lightness and firmness are the qualities necessary for leaping; everything should be done to acquire these two qualifications,

Fig. 6.

In leaping *without* a run, hold the legs and feet closed, bend the knees well up, hold forward the head, and throw out the hands, as in fig. 6. Skill in throwing forward the body with a jerk, thus doubled up, is only acquired by experience. Let great care be taken to descend with an inclination forward, and to fall on the fore-part of the feet, so as to touch the ground lightly, and by the spring or elasticity of the feet and limbs, to deaden the shock.

In leaping *with* a run, the run preceding the leap should never exceed ten paces; the rise into the air to take place at a distance from the cord equal to half the height of the cord from the ground. Skill should be attained in leaping from either foot, or from the spring of both feet. It is considered a good leap when five feet are cleared; a first-rate one is five and a-half; and an extraordinary one six feet; few, however, ever reach more than four feet. For a man to leap his own height—that is, for a man of six feet to leap six feet high, or a man of five feet eight inches to leap five feet eight inches high—is usually considered the perfection or ultimatum of the high leap. It may be noticed, however, that, all things considered, the man of medium size (about five feet eight inches) is almost always the most successful at this species of exercise.

What is gained in height is lost in distance. To make a long leap, therefore, it is not necessary to go high. The measurement of long leaps is by marks on level and soft ground, and he who clears the greatest number of marks is the most proficient. As in high leaping, the body must be inclined forward, and the spring made from the balls of the toes. To clear twelve feet without a run is considered a good leap. With a run of ten to fifteen paces, increased in velocity as the runner approaches the springing point, a leap may be performed of fourteen or fifteen feet. In this running leap, it is best to spring from the foot in which there is most proficiency, and to rise to a moderate height from the ground; too low a spring defeats the desired end, as must be evident to every one at all acquainted with the doctrines of Projectiles.

Leaping from a high to a low situation is another useful exercise. To acquire proficiency in it, begin with moderate heights, and learn to fall softly on the

balls of the toes, or fore-part of the feet. If the fall be upon the heels, the whole body is almost certain to be jarred, and the legs stove. Keep the body compact in the descent, with the hands well forward, so that, when alighting, the person may spring lightly up from a crooked or bent posture.

*Vaulting* is that kind of leaping in which the body is helped forward by a momentary leaning on an object by the hands. The art of vaulting may prove useful in many circumstances in life, as, for instance, in getting quickly over a paling, fence, or gate, to elude danger. Exercises are performed with vaulting bars, of which an illustration is given in fig. 7; they are of various heights, and some are shaped like a horse with a saddle.

Fig. 7.

Vaulting is performed with or without a run. The spring, as usual, is from the toes; and resting the hands on the bar, the legs are raised, and, by a jerk, pitched over to the other side. The pupil is to learn to vault in this manner, either towards the left or right. When perfect in the exercise, he learns to vault straight forward over the bar, between his hands, in which feat very great skill is necessary in doubling up the body and limbs during the spring. The methods of vaulting on and off horse-blocks are innumerable.

*Leaping with a pole* is a combination of simple leaping and vaulting, and is also a most useful and an elegant accomplishment. The pole should be smooth, light, and from seven to ten feet long. Held in the hands, as represented in fig. 8, the left hand below and the right above, the pole is planted with its lower point on the ground, and by a spring from the left foot, the body is impelled through the air to the desired distance.

Fig. 8.

In performing this exercise, the pupil must learn not to lean too much on the pole, and not to keep too close to it. The knack of pole-leaping is, like all other kinds, dependent on the spring of the feet, and the presence of mind in throwing the body forward lightly and gracefully. The best plan is to begin with short leaps across ditches, and to increase the distance as expertness is acquired. When the method of springing from a fixed situation is acquired, proceed to advanced practice by making a run, a rapid plant of the pole, and a spring to a considerable distance, as across a brook of twelve or fifteen feet in width.

The next step is to learn to vault over a high object by means of the pole. Two posts and a cross cord, as in fig. 9, are usually employed in this exercise. The leap is taken by a run, and 'upon this run,' observes Walker, 'principally depend the facility and success of the leap. As the spring can take place only with one foot, and as this must arrive correctly at the springing place, it is necessary that the order of the steps should be arranged so as to effect this object. The fixing of the pole in the ground and the spring must take place at the same instant, because by that means the upper and lower members operate together; no power is lost, and the swing is performed with the greatest facility. The leaper must carefully observe that the spring of the foot, and

Fig. 9.

the plant of the pole, are in the direction of (in a line with) the preparatory run.'

Carrying Weights.

A regular course of gymnastics embraces the art of lifting and carrying weights; but lessons in these exercises must be conducted with much caution, and only when the body has been otherwise well disciplined.

In lifting a weight, power is best exercised by doubling the body, as if about to sit down; the hands then grasp the ring of the weight placed between the feet, and the body gradually straightening, the arms rise with it, and lift what is in the hands. By this means the whole force of the body is exerted, and no part more than another.

Loads of any kind are most advantageously borne on the back and shoulders, with the body erect. The arrangement of knapsacks on the backs of soldiers is on this plan, the weight depending from each shoulder, and not hanging too low. The closer the load is to the shoulder, the shorter is the lever, and the less the pull on the point of resistance.

A man exercises his power of draught with the greatest advantage by pulling a rope over his shoulder, for in this case he throws forward the weight of his person, and he acts both by muscular energy and weight. The least advantageous exercise of his power is to carry a load up a ladder; for he has to carry up his own weight as well as the load which is on his shoulders.

Walking—Running.

The art of walking with ease, firmness, and grace, forms a necessary part of gymnastic or drill exercises. Few persons walk well naturally; the constraint of dress, distortion from labour, or bad habits of some kind, generally contributing to give a slounge to the figure, and an awkwardness to all the motions.

To walk gracefully, the body must be erect, but not stiff, and the head held up in such a posture that the eyes are directed forward. The tendency of untaught walkers is to look towards the ground near the feet; and some persons appear always as if admiring their shoe-ties. The eyes should not thus be cast downward, neither should the chest bend forward to throw out the back, making what are termed 'round shoulders;' on the contrary, the whole person must hold itself up, as if not afraid to look the world in the face, and the chest by all means be allowed to expand. At the same time, everything like strutting or pomposity must be carefully avoided. An easy, firm, and erect posture, is alone desirable. In walking, it is necessary to bear in mind that the locomotion is to be performed entirely by the legs. Awkward persons rock from side to side, helping forward each leg alternately by advancing the haunches. This is not only ungraceful, but fatiguing. Let the legs alone advance, bearing up the body. In setting down the feet, let the outer edge of the heel first touch the ground, and the sole of the foot bear and project the weight of the body. The length of step is of course to be determined by the length of limb. Efforts at taking long steps, out of proportion to the power of motion, are always ungraceful. Reckoning from heel to heel, or toe to toe, the length of a military step at drill march is thirty inches, which is considerably more than the length of ordinary steps in walking. The length of step at a moderate pace, of a man five feet nine inches high, is usually twenty-four inches; and this will be found a convenient length for most persons to acquire the habit of using.

The motion of the arms to and fro, in cadence with the movements of the legs, greatly helps the locomotion, and is advantageous in exercising the muscles of the shoulders, and expanding the chest. The motions of the arms, however, should be on a moderate scale, the hands not swinging through a greater space than eight or nine inches before and behind the leg. The practice of working forward the shoulders and swinging the arms at a great rate is most odious. It may be added, that the art of comporting the hands—that

is, of keeping them down in an easy, quiet position, and without meddling with the person—is one very necessary in polite behaviour, and should be acquired by all young persons, before bad habits are confirmed.

Running is a rapid leaping kind of walk, the leap being from each foot alternately, and the motion being promoted by throwing forward the weight of the person. The following are Walker's definitions of running, which we illustrate by fig.

10:—'The upper part of the body is slightly inclined forward; the head slightly thrown backward, to counteract the gravity forward; the breast is freely projected; the shoulders are steady, to give a fixed point to the auxiliary muscles of respiration; the upper parts of the arms are kept near the sides; the elbows are bent, and each forms an acute angle; the hands are shut, with the nails turned inwards; and the whole arms

Fig. 10.

move but slightly, in order that the muscles of respiration on the chest may be as little as possible disturbed, and follow only the impulse communicated by other parts. There exists, in fact, during the whole time of running, a strong and permanent contraction of the muscles of the shoulder and arm, which, though very violent, is less serviceable to the extended movements than to keep the chest immovable, toward which the arms are brought close, the flexors and adductors of which are especially contracted.

At every step the knees are stretched out, the legs kept as straight as possible, the feet almost graze the ground, the tread is neither with the mere balls of the toes nor with the whole sole of the foot, and the spring is made rapidly from one foot to the other, so that they pass each other with great velocity.

Speed, and still more duration in running, are in proportion to the development of the lungs, and consequently the volume of oxygen and blood which they can combine in their parenchyma at each respiratory movement. Thus of two men, one having the abdominal members developed, and the other possessing good lungs, the former will run with the greatest speed for a short distance; but if the distance be considerable, he will soon be gained upon by the latter. A runner, after performing a certain space, is seized with a difficulty of breathing long before the repetition of the contractions has produced fatigue in the abdominal members. To excel, therefore, in running, requires, like walking and dancing, a peculiar exercise. As the muscular contractions depend, for their principle of excitement, on the respiration, the chest should be firmly fixed, so as both to facilitate this, and to serve as a point of support for the efforts of the lower members. The best runners are those who have the *best wind*, and keep the breast dilated for the longest time.

During the whole time of running, long inspirations and slow expirations are of the greatest importance; and young persons cannot be too early accustomed to this practice. To facilitate respiration towards the end of the race, the upper part of the body may be leant a little forward. Running should cease as soon as the breath becomes very short, and a strong perspiration takes place.

Exercises in running should commence with very moderate distances, and for short periods of time; and great or fatiguing feats are only to be attempted after the body and lungs are strengthened by training.

TRAINING.

The method of training in modern times for pedestrian feats and other laborious undertakings, does not differ materially from that pursued by the ancient Greeks. The great object is to increase the muscular strength, and to improve the free action of the lungs

or wind of the person subjected to the process. The means adopted to accomplish the end in view is evacuation, to cleanse the stomach and intestines; sweating, to take off the superfluous fat and humours; daily exercise, to strengthen the muscles and system generally; and a peculiar regimen to invigorate the body. And to this we add the use of the tepid bath, to remove impurities and promote a healthy action in the skin. We present the following graphic account of the process of training from 'Walker's Manly Exercises':—

'The most effectual process for training appears to be that practised by Captain Barclay, which has not only been sanctioned by professional men, but has met with the unqualified approbation of amateurs. We are here, therefore, almost entirely indebted to it for details. According to this method, the pedestrian, who may be supposed in tolerable condition, enters upon his training with a regular course of physick, which consists of three doses. Glauber's salts are generally preferred; and from one ounce and a-half to two ounces are taken each time, with an interval of four days between each dose. After having gone through the course of physick, he commences his regular exercise, which is gradually increased as he proceeds in the training.

When the object in view is the accomplishment of a pedestrian match, his regular exercise may be from twenty to twenty-four miles a day. He must rise at five in the morning, run half a mile at the top of his speed up-hill, and then walk six miles at a moderate pace, coming in about seven to breakfast, which should consist of beefsteaks or mutton-chops under-done, with stale bread and old beer. After breakfast, he must again walk six miles at a moderate pace, and at twelve lie down in bed, without his clothes, for half an hour. On getting up, he must walk four miles, and return by four to dinner, which should also be beefsteaks or mutton-chops, with bread and beer, as at breakfast. After dinner, he must resume his exercise, by running half a mile at the top of his speed, and walking six miles at a moderate pace. He takes no more exercise for that day, but retires to bed about eight; and next morning he proceeds in the same manner.

Animal diet, it will be observed, is, according to this system, alone prescribed, and beef and mutton are preferred. All fat and greasy substances are prohibited, as they induce bile, and consequently injure the stomach. The lean of meat contains more nourishment than the fat; and in every case the most substantial food is preferable to any other kind. Fresh meat is the most wholesome and nourishing. Salt, spices, and all kinds of seasonings, with the exception of vinegar, are prohibited. The lean, then, of fat beef cooked in steaks, with very little salt, is the best; and it should be rather under-done than otherwise. Mutton, being reckoned easy of digestion, may be occasionally given, to vary the diet and gratify the taste. The legs of fowls are also esteemed.

It is preferable to have the meat broiled, as much of its nutritive quality is lost by roasting or boiling. It ought to be dressed so as to remain tender and juicy; for it is by these means that it will be easily digested, and afford most nourishment. Biscuit and stale bread are the only preparations of vegetable matter which are permitted to be given; and everything inducing flatulency must be carefully avoided. In general, the quantity of aliment is not limited by the trainer, but left entirely to the discretion of the pedestrian, whose appetite should regulate him in this respect.

With respect to liquors, they must be always taken cold; and home-brewed beer, old, but not bottled, is the best. A little red wine, however, may be given to those who are not fond of malt liquor; but never more than half a pint after dinner. It is an established rule to avoid liquors as much as possible; and no more liquor of any kind is allowed to be taken than is requisite to quench the thirst.

After having gone on in this regular course for three or four weeks, the pedestrian must take a four-mile sweat, which is produced by running four miles in flannel

at the top of his speed. Immediately on returning, a hot liquor is prescribed, in order to promote the perspiration; and of this he must drink one English pint. It is termed the sweating liquor, and is composed of one ounce of caraway seed, half an ounce of coriander seed, one ounce of root-liquorice, and half an ounce of sugar-candy, mixed with two bottles of cider, and boiled down to one half. He is then put to bed in his flannels, and being covered with six or eight pair of blankets and a feather bed, must remain in this state from twenty-five to thirty minutes, when he is taken out, and rubbed perfectly dry. Being then well wrapt in his greatcoat, he walks out gently for two miles, and returns to breakfast, which on such occasions should consist of a roasted fowl. He afterwards proceeds with his usual exercise.

These sweats are continued weekly till within a few days of the performance of the match; or, in other words, he must undergo three or four of these operations. If the stomach of the pedestrian be foul, an emetic or two must be given about a week before the conclusion of the training. He is now supposed to be in the highest condition for his feat.

Besides his usual or regular exercise, a person under training ought to employ himself in the intervals in every kind of exertion which tends to activity, such as golf, cricket, bowls, throwing quoits, &c. so that, during the whole day, both body and mind may be constantly occupied. Although the chief parts of the system depend upon sweating, exercise, and feeding, yet the object to be attained by the pedestrian would be defeated, if these were not adjusted each to the other, and to his constitution. The trainer, before he proceeds to apply his theory, should make himself acquainted with the constitution and habits of his patient, that he may be able to judge how far he can with safety carry on the different parts of the process. The nature of the patient's disposition should also be known, that every cause of irritation may be avoided; for as it requires great patience and perseverance to undergo training, every expedient to soothe and encourage the mind should be adopted.

The skilful trainer will, moreover, constantly study the progress of his art, by observing the effect of its processes, separately and in combination. If a man retain his health and spirits during the process, improve in wind, and increase in strength, it is certain that the object aimed at will be obtained; but if otherwise, it is to be apprehended that some defect exists, through the unskilfulness or mismanagement of the trainer, which ought instantly to be remedied by such alterations as the circumstances of the case may demand. It is evident, therefore, that in many instances the trainer must be guided by his judgment, and that no fixed rules of management can, with absolute certainty, be depended upon for producing an invariable and determinate result. In general, however, it may be calculated that the known rules are adequate to the purpose, if the pedestrian strictly adhere to them, and the trainer bestow a moderate degree of attention to his state and condition during the progress of training.

It is impossible to fix any precise period for the completion of the training process, as it depends upon the previous condition of the pedestrian; but from two to three months, in most cases, will be sufficient, especially if he is in tolerable condition at the commencement, and possessed of sufficient perseverance and courage to submit cheerfully to the privations and hardships to which he must unavoidably be subjected. The criterion by which it may be known whether a man is in good condition—or, what is the same thing, whether he has been properly trained—is the state of the skin, which becomes smooth, elastic, and well-coloured, or transparent. The flesh is also firm, and the person trained feels himself light and full of spirits. In the progress of the training, his condition may also be ascertained by the effect of the sweats, which cease to reduce his weight; and by the manner in which he performs one mile at the top of his speed. It is as difficult to run a mile at the top of one's speed as to

walk a hundred; and therefore, if he performs this trial well, it may be concluded that his condition is perfect, or that he has derived all the advantages which can possibly result from the training process.'

#### PEDESTRIAN FEATS.

Prepared by training, and acting under certain precautions as to food and rest, a person may perform very surprising feats of pedestrianism. He may, for instance, completely out-travel a horse, by walking for days continuously from thirty to forty miles, and yet be as fresh at the end of his journey as at the beginning. Without preparatory training, however, the most fatal injuries may be committed in attempting pedestrian feats. We must offer some precautionary advices on this subject:—

#### Advices to Young Men on Walking Excursions.

Young men who break away from regular, and perhaps sedentary, employment, to take a walking excursion of a few days in the country, often commit such grievous errors as mar their enjoyments, and deprive themselves of all the benefit they had calculated upon as the proper result of an exemption from ordinary duty. With soft and relaxed frames, they in many instances address themselves to walk such a distance each day as only could be conveniently walked by a person accustomed to such tasks. Accordingly, by the end of the second day at farthest, their feet are all over with blisters, their strength is completely exhausted, and their whole system is in a fever of nervous agitation, the consequence of enormous voluntarily-incurred suffering. The next morning, perhaps, sees them a little recovered, and, with their small stock of renewed strength, soaped stockings, and a vigorous resolution, they set out upon the third day's travel, which probably concludes by leaving them in a worse state than before. There is no time, however, to wait for a perfect recovery; so they travel on, and probably complete their excursion in a miserable dragging fashion, glad to get over the country without enjoying it, so that they only have the prospect of being again speedily at home and at rest.

This is the unavoidable consequence of ignorance and want of reflection. The excursion might have been a source of pleasure instead of pain, and might have added considerably to the youth's stock of ideas, instead of leaving him disgusted with the country and with nature, if he had only proceeded upon right principles. He ought to know that the body, after being long under the influence of a sedentary profession, or of ordinary city life, is not in a state fit for undertaking great fatigue. When soldiers, after being a considerable time in garrison, are about to undertake a long march, they usually are led out to take short walks each day for about a week beforehand, every day's walk lengthening a little, until they become fitted for the serious task. This they call being *beat into a march*. It is a practice founded on right physiological principles, and worthy of being followed by every individual in like circumstances. In the walks of the first two or three days, young pedestrians should not set themselves to any certain number of miles, but only walk as far as they feel their strength will agreeably carry them. Thus they will gradually acquire power, instead of losing it, and in the long-run become good walkers, enjoying the country, moreover, as they go along, and leaving off with an increased love of nature, and a disposition to have another such excursion at the first opportunity.

Young travellers, and old ones too, often make a great mistake with regard to eating. They suppose that, having much fatigue to undergo, they ought to eat a great deal; and the excitement of novelty, and the tempting and unusual food presented at inns, enable them to carry out this idea into practice. In a few days, however, they find themselves unaccountably unwell. This is the consequence of simple over-eating, for in travelling there is no need for more food than

usual. Food is also taken at wrong times, and of wrong kinds. It is not uncommon for young pedestrians to walk ten or twelve miles before breakfast, not so much for any economy of time or money, as under the impression that they will have a capital appetite at the end of their walk. As they go along, they delight themselves with reflections as to how they will astonish the waiters, how fresh relays of eggs will be called for, and rolls vanish like morning dreams. Alas! when they have walked their dozen miles, their frames are in a state the most unsuited for the receipt of a full meal; and if they are able to eat largely, it will be the worse for them after. The whole aim here is the very reverse of what it ought to be. A very full meal should never be taken on a pedestrian excursion, and that simply for the reason that there is no time to digest a very full meal. A breakfast or dinner during a walking excursion, when only a little time can be allowed for rest afterwards, should be light. Whether light or heavy, the longer the rest afterwards the better—that is, of course, within a reasonable limit. Certainly the rest should not be less than three-quarters of an hour; and if a heavy meal have been taken, half an hour longer will be required at the very least.

Many young travellers have the prudence to fare slightly during their day's walk, but on getting to their inn in the evening, they make all up, as they think, by taking a great composite meal—dinner, tea, and supper rolled into one. If, as often happens, this be taken pretty late, the tea keeps them awake half the night, by virtue of its exciting power. But it may act injuriously in another way. When much of it is taken in proportion to the solids, it prevents digestion. The gastric juice, it must be understood, requires that what is submitted to it should possess a certain solidity. It is for this reason that nature has so arranged, in the case of sucking infants, that the milk curdles immediately after being taken, the gastric juice being thereby enabled to catch hold of it. When a young man, after exhausting his energies by a long walk, fills his stomach with a great *blushy* meal, he commits one of the greatest of imprudences. The gastric juice gets mixed and confounded with the mass, and several hours will elapse before any progress whatever be made in digestion. Many is the sleepless night endured on this account on summer excursions. It is obviously necessary that, if tea is to be taken at all at a late hour, it should be weak, and in quantity strictly proportioned to the solids taken at the same time. Weak coffee, however, ought always to be preferred to tea, if to be taken near bedtime, as its exciting power is much less.

The rules here laid down are all of them grounded on natural principles, which will be found more particularly explained in physiological works—those, for instance, of Dr Combe and Dr Robertson, which are by far the most intelligibly written, at the same time that they are even more philosophical than most others. (See Nos. 8, 45, and 46 of this series, Vol. I.) By attending to such rules, a rural excursion may be made very delightful, and may have the best effects on both body and mind; while neglect of them as certainly must entail pain and disappointment.

#### Captain Barclay's Feats of Walking.

Captain R. Barclay Allardice of Ury, an enthusiastic cultivator of manly sports, is well known as having some years ago performed various remarkable feats of pedestrianism, and his mode of walking is well worthy of notice. Pierce Egan thus writes of his performances:— 'His style of walking is to bend forward the body, and throw its weight on the knees. His step is short, and his feet are raised only a few inches from the ground. Any person trying this plan will find his pace quickened, and he will walk with more ease to himself, and be better able to endure the fatigue of a long journey, than by walking perfectly erect, which throws too much of the weight of the body on the ankle-joints. He always uses thick-soled shoes and lambs'-wool stockings, which preserve the feet from injury.'

## OUT-OF-DOOR RECREATIONS.

We have not space to include an account of the various extraordinary feats performed by this able pedestrian, and shall only notice his famous match with Mr Webster in October 1808. 'The captain engaged himself to go on foot a thousand miles in a thousand successive hours, at the rate of a mile in each and every hour, for a bet of one thousand guineas, to be performed at Newmarket heath, and to start on the following 1st of June. In the intermediate time, the captain was in training by Mr Smith of Owston in Yorkshire. He started on his match at twelve o'clock at night on Thursday, the 1st of June, in good health and high spirits. His dress from the commencement varied with the weather. Sometimes he wore a flannel jacket, sometimes a loose gray coat, with strong shoes, and two pair of coarse stockings, the outer pair boot-stockings without feet, to keep his legs dry. He walked in a sort of louncing gait, without any apparent extraordinary exertion, scarcely raising his feet two inches above the ground. During a great part of the time the weather was very rainy, but he felt no inconvenience from it; indeed, wet weather was favourable to his exertions; as, during dry weather, he found it necessary to have a water-cart to go over the ground to keep it cool, and prevent it becoming too hard. Towards the conclusion of the performance, it was said, the captain suffered much from the spasmodic affection of his legs, so that he could not walk a mile in less than twenty minutes; he, however, ate and drank well, and bets were two to one and five to two on his completing his journey within the time prescribed. About eight days before he finished, the sinews of his right leg became much better, and he continued to pursue his task in high spirits, and consequently bets were ten to one in his favour in London, at Tattersall's, and other sporting circles.

On Wednesday, July the 12th, Captain Barclay completed his arduous undertaking. He had till four P. M. to finish his task, but he performed the last mile by a quarter of an hour after three in perfect ease and great spirit, amidst an immense crowd of spectators. The influx of company had so much increased on Sunday, that it was recommended that the ground should be roped in. To this, however, Captain Barclay objected, saying that he did not like such parade. The crowd, however, became so great on Monday, and he had experienced so much interruption, that he was prevailed upon to allow this precaution to be taken. For the last two days he appeared in higher spirits, and performed his last mile with apparently more ease, and in a shorter time, than he had done for some days past.

With the change of weather he had thrown off his loose greatcoat, which he wore during the rainy period, and walked in a flannel jacket. He also put on shoes thicker than any which he had used in the previous part of his performance. When asked how he meant to act after he had finished his feat, he said he should that night take a good sound sleep, but that he must have himself awaked twice or thrice in the night to avoid the danger of a too sudden transition from almost constant exertion to a state of long repose. One hundred guineas to one, and indeed any odds whatever, were offered on Wednesday morning; but so strong was the confidence in his success, that no bets could be obtained. The multitude who resorted to the scene of action in the course of the concluding days was unprecedented. Not a bed could be procured on Tuesday night at Newmarket, Cambridge, Bury, or any of the towns or villages in the vicinity, and every horse and vehicle was engaged. Among the nobility and gentry who witnessed the conclusion of this extraordinary performance, were the Dukes of Argyle and St Alban's; Earls Grosvenor, Besborough, and Jersey; Lords Foley and Somerville; Sir John Lade, Sir F. Standish, &c. &c. The aggregate of the bets is supposed to have amounted to £100,000. Upon the whole, Captain Barclay must be viewed as a most extraordinary man; his feats exhibiting the extent of vigour that the human frame derives from exercise.'

## OUT-OF-DOOR RECREATIONS.

### SWIMMING.

The art of swimming is so exceedingly useful, not only as a bracing summer exercise, but as a means of preserving life when accidentally plunged into the water, that it should be acquired by every young person. It may be performed either in the sea or in rivers; but the sea is preferable, as salt water is of a greater specific gravity than fresh, and has the greater power of buoying up the body. Whether in fresh or salt water, however, the body is lighter, bulk for bulk, than the mass of liquid displaced, and consequently will float if a small aid be given by the impulsion of the hands. It is also important to observe, that the more the body is immersed in the water, the more easily is it sustained. Thus if only the face is left above the surface, the buoyancy will be much greater than if the whole head or the head and hands were exposed. When persons unskilled in swimming are plunged into the water, as, for instance, by the upsetting of a boat, they ought, for the reasons now mentioned, not to struggle, splutter, and hold the hands up, but remain tranquil, with as little above water as possible; draw in the breath so as to fill the lungs, and sustain themselves by a paddling motion with the hands.

### Practical Directions for Swimming.

The best season for bathing in the sea or rivers is summer and autumn, and the time of day most preferable is the morning before breakfast; the next best time is before dinner. Immediately after dinner, or when the stomach is full, is injurious. A person also should never bathe twice in one day, or continue in the water more than twenty minutes at one time. To avoid the danger of propelling the blood to the head, by stepping suddenly into cold water, always wet the head first. Bathing is best performed when entirely naked; but if this be unsuitable, short drawers may be used.

Young persons or others unskilled in swimming should not on any account go beyond the depth of breast-high, till they are able to buoy themselves up freely. They can commence their lessons in swimming by throwing themselves forward, and trying what will be the effect of a throwing out of hands and feet, keeping only the head above the surface. Some persons tie corks or bladders about their neck or breast; but this we discommend as dangerous. A preferable plan of learning to swim is to receive the aid of a person skilled in the art, who will help to buoy up the learner with his hand, and withdraw his assistance gradually. In ordinary circumstances, however, any young person may acquire the art himself.

The learner having thrown himself forward, he must draw his head back, elevate his chin clear of the surface, project his breast, hollow his back, and be firm and collected. Fear must be entirely thrown aside. Instead of putting down the hands, as if to grope for something, which is a very common error, throw the hands boldly forward, and strike out with them. The plan of doing this is first to bring the hands together, with the fingers close, and the thumbs closed to the fore-fingers; then strike out with the palms undermost, and slightly hollowed. The hands must not touch the surface in striking, but make a sweep level with the breast, and as far out as possible. Next, they are to be drawn back with a rapid movement; in this retraction the elbows are to be bent, and the hands drooping downwards, so that as little obstacle as possible may be presented to the water. The hands being brought together as before, they are to be struck out in the same manner; and so on.

The hands furnish only half the means of advancing. The other half are the legs, which must be sent out behind with a jerk to their full extent, the soles pushing against the water. The position of the swimmer in the water is indicated in the following cut, fig. 11, in which it will be seen that the body slopes from the

neck to the feet. To advance properly, and secure regular buoyancy, the hands and feet must act alternately, the arms descending while the legs are rising, and the arms rising while the legs are descending.

Fig. 11.

Besides regulating the action of the hands and feet, the swimmer must regulate his breathing. The breath is to be inhaled when the body is rising by the descent of the hands, and when the mouth is clearly above the ruffle of the water. This fills the chest with air at the moment most advantageous to do so. The breath is to be expended at the next impulse forward by the legs. Some persons, in learning to swim, acquire the habit of *breasting*, or rising high out of the water at every stroke of their arms; this mode of swimming is not only ungraceful but fatiguing; a good and tasteful swimmer advances smoothly through the water, with a moderate rise, and at a moderate and steady rate of speed.

There are various fanciful modes of swimming; one of these is swimming with the back downwards, as represented in fig. 12.

Fig. 12.

In this case, the head is more immersed than in ordinary swimming, and consequently less labour is required to buoy up the body. The method employed is to lie gently back in the water, with the hands on the thighs, and to strike out the legs as in front swimming. By swimming on the back little progress is made, and it is chiefly useful as a relief to the arms.

Another means of relieving the fatigue of swimming, is to float on the back with a very gentle motion of the legs, in the position represented in fig. 13.

Fig. 13.

The arms are extended, the chin and mouth elevated higher than the forehead; and the water is to be agitated as little as possible, so as not to enter the mouth.

Swimming with one arm is sometimes useful. To perform this feat, the head should be held more backward than usual; the swimmer hold himself more erect; the legs and arm must be exercised pretty quickly; and with force the hand should be struck out against the body, and so brought down before, the arm extended its full length for every stroke. The swimmer must, however, be very careful to keep his breast inflated, as this mode of swimming requires more than ordinary dexterity. Should the swimmer draw in his breast imprudently, when his arms are raised, he would immediately sink to the bottom.

Diving is the art of descending rapidly in the water, and requires to be done with address. The best method consists in drawing in the breath, placing the two hands together as a cut-water in front, and then to plunge head foremost, causing the forehead to receive the force of the fall. In taking the water, the eyes, for safety, should be shut; but they may be opened when beneath the surface, when the body assumes the swimming attitude. Swimming below the water is so exceedingly easy that it requires no directions.

Mr Frost, in his small work on 'Scientific Swimming,' presents the following practical rules for sportive swimming:—'To spin with ease, the person should be somewhat buoyant; the breast must be well inflated, and the attitude may be that of sitting with the feet crossed. It is effected by embracing the water with

each hand, alternately, on the same side. In order to turn to the right, the water must be embraced with each hand, alternately, on the right side; and to turn to the left, on the left side. This action causes a circular or spinning movement, which increases in velocity as it is continued. Of all the playful ways of swimming he ever knew, the author considers this to be the most curious. He has seen boys sportively rolling along the stream, and conceived it very much to resemble the juvenile amusement, on a summer day, of rolling down a declivity. The stream is the most favourable situation for rolling, as it very much assists the turn. To achieve this, the person must lay himself straight across the current; he must inflate his breast, and hold his head very far backward; his legs may either lie together or be crossed; he must exercise his hands in the same manner as in spinning. By this alternate action of the hands, with the assistance of the stream, some persons will roll along in a pleasing and extraordinary manner.' He then mentions quadruped swimming; but neither the posture nor action is agreeable.

In some cases cramp takes place in the water, and the swimmer requires to be prepared for its attacks. The following directions by Walker, acted upon with due self-possession, comprise all that need be said in this place on this subject:—

'As to cramp, those chiefly are liable to it who plunge into the water when they are heated, who remain in it till they are benumbed with cold, or who exhaust themselves with violent exercise. Persons subject to this affection must be careful with regard to the selection of the place where they bathe, if they are not sufficiently skilful in swimming to vary their attitudes, and dispense instantly with the use of the limb attacked by cramp. Even when this does occur, the skilful swimmer knows how to reach the shore by the aid of the limbs which are unaffected, while the uninstructed one is liable to be drowned.

If attacked in this way in the leg, the swimmer must strike out the limb with all his strength, thrusting the heel downward, and drawing the toes upward, notwithstanding the momentary pain it may occasion; or he may immediately turn flat on his back, and jerk out the affected limb in the air, taking care not to elevate it so high as greatly to disturb the balance of the body. If this does not succeed, he must paddle ashore with his hands, or keep himself afloat by their aid, until assistance reach him. Should he even be unable to float on his back, he must put himself in the upright position, and keep his head above the surface by merely striking the water downward with his hands at the hips, without any assistance from the legs.'

#### SKATING.

This is a highly-exhilarating and healthful out-of-door pastime in winter, when rivers and ponds are frozen, and offer a clear surface of ice. The art of skating consists in poising the body on a sharp ridge of iron beneath the sole of the foot, and advancing on the ice in that position, one foot relieving another. As a very slender base will support any mass of matter kept in motion, skating is by no means a difficult art, and requires only courage, quickness of eye, and delicacy of taste, to render the performances elegant.

A skate is a well-known apparatus of wood and iron, with straps and buckles to attach it to the foot. The skate for each foot must be alike. The iron should not be deeper than three-quarters of an inch, and smooth or flat along its under edge; only boys' skates should be grooved, to take better hold of the ice. The iron should be a quarter of an inch thick. The edges should be smooth, free from rust, and sharply ground.

#### Practical Directions for Skating.

We beg to offer the following directions to the young skater, chiefly from the work of Mr Walker:—

'Either very rough or very smooth ice should be avoided. The person who for the first time attempts

## OUT-OF-DOOR RECREATIONS.

to skate must not trust to a stick. He may make a friend's hand his support, if he require one; but that should be soon relinquished, in order to balance himself. He will probably scramble about for half an hour or so, till he begins to find out where the edge of his skate is. The beginner must be fearless, but not violent, nor even in a hurry. He should not let his feet get far apart, and keep his heels still nearer together. He must keep the ankle of the foot on the ice quite firm; not attempting to gain the edge of the skate by bending it, because the right mode of getting to either edge is by the inclination of the whole body in the direction required; and this inclination should be made fearlessly and decisively.

The leg which is on the ice should be kept perfectly straight; for though the knee must be somewhat bent at the time of striking, it must be straightened as quickly as possible, without any jerk. The leg which is off the ice should also be kept straight, though not stiff, having an easy but slight play, the toe pointing downwards, and the heel within from six to twelve inches of the other.

The learner must not look down at the ice, nor at his feet, to see how they perform. He may at first incline his body a little forward, for safety, but hold his head up, and see where he goes; his person erect, and his face rather elevated than otherwise.

When once off, he must bring both feet up together, and strike again, as soon as he finds himself steady enough, rarely allowing both feet to be on the ice together. The position of the arms should be easy and varied, one being always more raised than the other; this elevation being alternate, and the change corresponding with that of the legs; that is, the right arm being raised as the right leg is put down, and *vice versa*, so that the arm and leg of the same side may not be raised together.

The face must be always turned in the direction of the line intended to be described. Hence, in backward skating, the head will be inclined much over the shoulder; in forward skating, but slightly. All sudden and violent action must be avoided. Stopping may be caused by slightly bending the knees, drawing the feet together, inclining the body forward, and pressing on the heels. It may also be caused by turning short to the right or left, the foot on the side to which we turn being rather more advanced, and supporting part of the weight.

The first attempt of the beginner is to walk, and this walk shortly becomes a sliding gait, done entirely on the inside edge of the skate.

The first impulse is to be gained by pressing the inside edge of one skate against the ice, and advancing with the opposite foot. To effect this, the beginner must bring the feet nearly together, turn the left somewhat out, place the right a little in advance, and at right angles with it, lean forward with the right shoulder, and at the same time move the right foot onwards, and press sharply, or strike the ice with the inside edge of the left skate—care being taken instantly to throw the weight on the right foot. While thus in motion, the skater must bring up the left foot nearly to a level with the other, and may for the present proceed a short way on both feet.

He must next place the left foot in advance in its turn, bring the left shoulder forward, inclining to that side, strike from the inside edge of the right skate, and proceed as before.

Finally, this motion has only to be repeated on each foot alternately, gradually keeping the foot from which he struck longer off the ice, till he has gained sufficient command of himself to keep it off altogether, and is able to strike directly from one to the other, without at any time having them both on the ice together. This must be practised till he has gained some degree of firmness and power, and a command of his balance.

Thus accomplished in the rudiments of the art, the skater may proceed to learn the *forward roll*, which is the first step to figure-skating. 'The impulse is gained

in the same manner as for the ordinary run; but to get on the outside edge of the right foot, the moment that foot is in motion, the skater must advance the left shoulder, throw the right arm back, look over the right shoulder, and incline the whole person boldly and decisively on that side, keeping the left foot suspended behind. As he proceeds, he must bring the left foot past the inside of the right with a slight jerk, which produces an opposing balance of the body; the right foot must quickly press, first on the outside of the heel, then on the inside, or its toe; the left foot must be placed down in front before it is removed more than about eight or ten inches from the other foot; and by striking outside to the left, giving at the same moment a strong push with the inside of the right toe, the skater passes from right to left, inclining to the left side in the same manner as he did to the right. He then continues to change from left to right, and from right to left, in the same manner. At first he should not remain long upon one leg, nor scruple occasionally to put the other down to assist; and throughout he must keep himself erect, leaning most on the heel.'

Having attained this proficiency, there will be little difficulty in describing any figure, formed by a combination of circles or semicircles. The figure 8 is a favourite among clever skaters, and also the figure 3, both forward and reversed.

Skating on ice of doubtful strength is accompanied with great danger; as in an instant the skater may find himself sunk to the neck in water, and be drowned before assistance can be rendered. Much of this danger may be obviated by wearing a *safety-cape*, which is a loose cape, of some waterproof fabric, inflated with air. We recommend every skater to use by all means a cape of this kind while pursuing his amusement on the ice.

### CURLING.

Curling is a game of great antiquity and popularity in the southern and western parts of Scotland. It is a winter game, played on the ice; and where the rivers and ponds are frozen, usually supersedes all other out-of-door amusements. As the ice requires to be much thicker than for skating, it is usual to form ponds so shallow that the whole water in them becomes a frozen mass capable of bearing up any weight.

The game is played by a party forming rival sides, each individual being possessed of a circular hard stone, of about nine inches in diameter, flat and smooth on the under side, and on the upper, having a handle fixed to the stone. Each player is likewise armed with a broom to sweep the ice, in order to accelerate the progress of the stones; and his feet are ordinarily furnished with trampets or crampets, which help to steady him in taking his aim. A large, long, open space of ice, of from thirty to forty yards in length, and eight or nine feet across, called a *rink*, being cleared, and a mark or *tee* being made at each end to play to, the contest takes place by each person hurling or causing his stone to slide towards the opposite end of the rink. A certain number being the game, the object of each side is, which will have the greatest number of stones nearest the tee; and all play from end to end alternately till this is ascertained. To hurl these stones with precision, in this species of sport, is exceedingly difficult; much depending on the keenness of the frost, the tone of the ice, and the truth of the stone. Sometimes the best and oldest players are baffled by beginners, simply by their curling-stones having taken a bias to one side or another; and frequently, after the best players have placed their stones in a cluster round the tee, one rapid shot from an antagonist will disperse the whole in all directions round. Occasionally it also happens that, in hurling, the stones come far short of the mark; but if they do not get beyond a line called the *hogg score*, they are dragged aside, and are not counted. A more than usually extensive match is called a *bonspiel*.

Such is a meagre outline of the game of curling, which, all over the lowlands of Scotland during the

keen frosty days of winter, engages all classes of persons in its exciting sport. Parish contends against parish, county against county, club against club, in universal mirthful rivalry. At Edinburgh, where there are neither

rivers nor ponds, the inhabitants usually resort for the amusement of curling, as well as skating, to the adjacent beautiful small lake at Duddingston, lying at the south-eastern base of Arthur Seat. Here a most animated scene is exhibited during the period that the waters of the lake are frozen. Numbers of rinks are cleared, at which may be seen playing together persons in almost every shade of society—professors of the university, clergymen, private gentlemen, merchants, tradesmen, and artisans—all meeting on a common level, and engaged in the same spirit-stirring pursuit; for in curling there is no aristocracy of feeling, and so, for the time, a universal saturnalia prevails. The game of curling is eulogised by more than one Scottish poet, particularly by Grahame, who thus commences a description of the sport:—

' Now rival parishes and shrievedoms keep,  
On upland lochs, the long-expected tryst,  
To play their yearly bonspiel. Aged men,  
Smilt with the eagerness of youth, are there,  
While love of conquests lights their beamish eyes,  
New-nerves their arms, and makes them young once more.'

In Mr J. McDiarmid's 'Sketches of Nature,' we find the following spirited account of this delightful and invigorating winter game:—

'The time is not distant when the game of curling was little known out of Scotland, or even within it, beneath the Forth. But the taste for this manly sport has increased greatly of late years; and in various parts of England, as well as of America, the broom and the channel-stone are put in requisition with the same regularity that winter comes round.

In the whole range of rural sports, I know nothing more exhilarating than a *spiel* on the ice, where the players are numerous and well-matched—the stakes a dinner of beef and greens—and the forfeit the honour of rival parishes. All around is blank and dreary—the snow-flake freezes as fast as it falls—the sun seems level with the horizon's verge—the hills make the spectator cold to look at them—and everything, in one word, conspires to complete the picture of a winter's day. But the courage of men bent on the favourite amusement of curling is not easily damped by the inclemency of the elements; on the contrary, their spirits seem to mount as the thermometer falls, and nothing pleases them more than a feeding storm, and, along with that, the prospect of a long lease of "their roaring play." Arrived at the scene of action, all is bustle and animation, till the stones have been distributed, assorted, claimed—rinks measured, tramps fastened, tees fixed, and the order of battle completely arranged; and as these preliminaries are speedily settled, to it the parties set with all the anxiety of those who contend for a much higher prize. Lots, perhaps, are cast for the first shot, and the greatest novice invited to deliver the first stone; and should his arm lack the proper pith, that instant a dozen brooms are raised to help the laggard over the *hogg score*. A second, a

third, a fourth succeeds, and so on, till the line stretches a tolerable length; and each man is warned by his respective friends to plant, if possible, an excellent guard—dislodge this stone, and cover that—open up one port, and close another—play soft or strong, outside or inside, as the occasion may require—and steer as closely by the signal broom as the *mariner*, when warned by similar devices, threads his watery way through sand-banks and shallows.

As the animating sport deepens, it is amusing to contrast the bustle that obtains in one little spot with the stillness that broods over the external world. While the hills above are silent and dark, the shining lake below is instinct with life, and resounds with sounds of mirth and glee, which, borne along on the elastic air, invade the solemn loneliness that reigns around, till echo itself takes up the tale, and repeats in broken fragments the curler's vocabulary. At length, as the more veteran players advance to decide by their skill the fate of the *side*, the interest becomes intense, and gives rise to so many calculations of what is to be done, and what avoided, such bustling to and fro, as must appear a perfect mystery to the uninitiated. The last wary shot booms athwart the ice as if impelled by magic, and while every port, to an onlooker, seems closed, finds its way, under the guidance of a powerful arm and steady eye, through passages rivalling the intricacy of the walls of Troy. Then follow the shout of victory and the murmur of defeat, till the contest is renewed under the mingled emotions of hope and fear—the vanquished trusting that the tables will be turned, and the conquerors confident they will remain the same. Speedily the eager players are marshalled, and the broom put in requisition as before; again the stones boom away and away, meandering here, meeting there, and whirling from the collision like the urchin's top at school; again shot succeeds shot, and game follows game, until the conclusion of the *bonspiel*, or the approach of evening, proclaims that it is time the sport should surcease, and the combatants wend their way to the nearest *clachan*, to enjoy their favourite feast of beef and greens. And now the scene changes entirely, though, as the savoury viands load the board, all feel the effects of the keen mountain air, and make so good a use of their time while the opportunity serves, that the business of eating becomes nearly as noisy as the business of play; rounds of corn-beef, flagons of home-brewed, disappear with a rapidity that is truly astonishing, and of which no adequate conception can be formed by persons whose appetites were never whetted by a day on the ice.'

#### Laws and Regulations for Curling.

In the year 1838 was instituted the Grand Caledonian Curling Club, for the purpose of uniting all curlers into a 'brotherhood of the rink,' and of regulating the game by general laws, which have now been adopted by all local curling associations. From the Annual published by the club we extract the following as the rules of the game:—

1. The length of the rink shall be forty-two yards; any deviation occasioned by peculiar circumstances to be by mutual agreement of parties. When a game is begun, the rink is not to be lengthened nor shortened, unless by consent of the majority of players.

[It is advisable that rinks have double tees at each end, the one at least two yards behind the other, the whole four to be as nearly as possible in the same line. The stones are to be delivered from the outer tee, and played towards the inner; this saves the ice from being injured around the tee played up to.]

2. The rink shall be changed in all cases when, from the springing of water, the majority of players cannot make up. Neither the winning nor losing party have right to object, as all contests must be decided on the fair and equitable principle of science, not of strength.

3. The number of shots in a game, if not otherwise mutually fixed upon, shall be twenty-one.

[A game more frequently consists of thirteen shots, or even of seven, than of any others, when an hour or two's practice only is intended; but this is a matter of private arrangement.]

In a bonspiel or match, when a considerable number of players appears on each side, the aggregate number of shots gained in a fixed time is not only as equitable a method, but affords amuse-

## OUT-OF-DOOR RECREATIONS.

ment to all the rink to the conclusion, and ought to be universally adopted.]

4. The hogs' score to be one-sixth part of the length of the rink from the tee. Every stone to be considered a hog which does not clear a square placed upon the score.

5. Every rink to be composed of four players a side, each with two stones, unless otherwise mutually agreed upon. In no case shall the same individual or party play two stones in succession, and every player shall deliver both his stones alternately with an opponent, before any other of the same side or party play one.

6. Parties to draw outs which shall fill the ice at the first end; after which the winning party at the last end or game of that day's play shall do so. No stone to be counted which does not lie within seven feet from the tee, unless it be previously otherwise mutually agreed upon. In cases where each party has a stone equally near the tee, neither to be counted, and the winning party of the previous end is again to fill the ice. Measurements to be taken from the centre of the tee to that part of the stone which is nearest it.

7. Each player to place his shot in such a manner as that, in delivering his stone, he shall bring it over the tee. A player stepping aside to take a brittle (or wick), or other shot, shall forfeit his stone for that end. A player, after delivering his last stone, shall not remain longer than to see his next opponent fit his toe, but shall take his place at the other end between the score and the previous player of his own party; and shall on no account remain to give directions to the next of his party who plays.

8. If any player shall improperly speak to or interrupt another while in the act of delivering his stone, one shot shall be added to the score of the party so interrupted.

9. The rotation of play adopted at the beginning must be observed through the whole game.

10. All curling stones shall be of a circular shape. No stone must be changed throughout the game, unless it happen to be broken, and then the largest fragment to count, without any necessity of playing with it more. If a stone rolls and stops upon its side or top, it shall not be counted, but put off the ice. Should the handle quit the stone in the delivery, the player must keep hold of it, otherwise he will not be entitled to replay the shot.

11. If a player plays out of turn, the stone so played may be stopped in its progress, and returned to the player. If the mistake shall not be discovered till the stone is again at rest, the opposite party shall have the option to add one to their score, and the game proceed in its original rotation, or, to declare the end null and void.

12. In double-soled stones, the side commenced with shall not, under pretext of the match, be changed during the progress of the game.

[Double-soled stones are those in which the handle can be shifted from one side to another; one side being slightly concave for keen ice, and the other convex for dull ice.]

13. The sweeping department to be under the exclusive control of the skipper. No sweeping to be allowed by any party till the stone has passed the hogs' score, except when snow is falling or drifting, in which case it shall be admissible to sweep from tee to tee. The player's party may sweep when the stone has passed the further hogs' score, his adversaries' when it has passed the tee. Sweeping to be always to one side. Previous to each direction being given, either party is entitled to sweep the rink clean.

14. Parties, before beginning to play, to take different sides of the rink, which they are to keep throughout the game; and no player, on any pretence, to cross or go upon the middle of the rink. The skippers alone to stand about the tee. Their respective parties, according to their rotation of play, shall take their position down to the hogs' score.

15. If in sweeping, or otherwise, a running stone be marred by any of the party to which it belongs, it shall be put off the ice. If by any of the adverse party, it shall be placed where the skipper of the party to whom it belongs shall direct. If marred by any other means, the player shall take his shot again. Should a stone at rest be accidentally displaced at any part of the end before the case provided for in rule 13 comes into operation, it shall be put as nearly as possible in its former position.

16. Every player to come provided with a besom, to be ready to play when his turn comes, and not to take more than a reasonable time to throw his stones. Should he accidentally play a wrong stone, any of the players may stop it while running; but if not stopped till it is again at rest, it shall be replaced by the one which he ought to have played.

17. No measuring of shots allowable previous to the termination of the end. Disputed shots to be determined by the skippers; or, if they disagree, by some neutral person mutually chosen by them, whose decision shall be final.

18. Should any played stone be displaced before the last stone is thrown and at rest, by any of the party who are lying the shot, they shall forfeit the end; if by any of the losing party who have the stone yet to play, they shall be prevented from playing that stone, and have one point deducted from their score. The number of shots to be marked by the winners to be decided by the majority of the players, the offender not having a vote.

19. The skippers shall have the exclusive regulation and direction of the game, and may play in what part of it they please; but having chosen their place at the beginning, they must retain it till the end of the game. The players may give their advice, but cannot control their director; nor are they upon any pretext

to address themselves to the person about to play. Each skipper, when his own play comes, shall name one of his party to take charge for him. Every player to follow implicitly the direction given him.

20. Should any question arise, the determination of which is not provided for by the words and spirit of the rules now established, it may be referred to the three nearest members of the representative committee, unconnected with the disputing parties, who shall form a district committee of reference, and whose decision shall be binding on all concerned till the annual general meeting of the representative committee, to whom either party may appeal the case.

### CRICKET.

This is perhaps the best of all out-of-door sports for youth. It requires quickness of mind and eye, great agility of limb, and, properly conducted, is highly exhilarating and amusing. The game is played on an open well-shaven green, which is level, and free from stones or shrubs; it should also be dry, and of sufficient dimensions to allow of a good blow to the ball and run—a square field of three or four acres is a good size. The apparatus required in the game consists of balls, bats, and wickets. The dress of the players should be light and easy—a white woollen jacket, cap, linen trousers, and shoes provided in the soles with points to prevent slipping in running: in London there are shoes made purposely for cricketing.

Cricket is played in two distinct forms; one is called *Single Wicket*, and the other *Double Wicket*. We shall first give an outline of *Single Wicket*.

*Single Wicket*.—This game is played by any number of persons, but generally *five* are on each party or side. Three straight rods or *stumps*, twenty-seven inches high, are stuck in a row in the ground; on the top of the stumps are laid two pieces of wood called the *bat*, and so placed that they will readily fall off if the stumps be hit by the ball. This apparatus is called the *wicket*. At the distance of four feet four inches in front of the wicket is a mark on the ground called the *popping-crease*. In a straight line with the wicket is a mark on the ground called the *bowling-crease*, which is parallel to the bowling-crease.

An individual taken from one party is appointed *bowler*; his duty is to bowl his ball towards the opposite wicket, which he does by a short run. An individual from the antagonist party is appointed *batter*; his duty is to stand with his bat placed with its tip on the ground at the popping-crease, and to oppose the progress of the ball, or to prevent it from knocking down his wicket. He must also endeavour to strike the ball smartly, so as to send it to a distance on the field. The field is in charge of the party to which the bowler belongs; these are termed *field-men*, or *field-keepers*, and each has an appointed place, from which he takes a peculiar designation: one is named the *leg-hit*, or *long stop*, another the *off-hit*, a third the *long field on*, a fourth the *long field off*. Their duties are to catch the ball when either struck or missed by the batter.

If the ball be missed by the batter, he remains at his wicket, and the ball is returned by the long stop to the bowler. If the ball be struck, and to such a distance

## CHAMBERS'S INFORMATION FOR THE PEOPLE.

that the batter thinks he could run to the bowling-crease, touching it with his bat, and return to his popping-crease, touching it also before the ball is returned and strikes the wicket, he does so; and if he perform this feat successfully, it is called *one run*, and counts one towards the game. Sometimes he strikes the ball to such a great distance that he can run to and fro twice, and this counts two; if three times, it counts three; and so on. These are termed *runs* or *notches*.

Should the bowler knock down the wicket, the batter retires, and this finishes his *inning*. His *inning* is also finished by the wicket being knocked down with the ball by any of the field-keepers, if he be off his ground. The *inning* may likewise be finished (as it frequently is) if the batter strikes the ball into the air, and it be caught by any of the batter's antagonists before it reaches the ground, and retained long enough to be thrown up again.

*Double Wicket*, which is considered the true game of cricket, is like two games of single wicket playing at one time, there being two wickets from which to bowl; also two batters, but only one ball. This game is played as above, with this difference, that the batter runs only to the opposite end, exchanging places with the other batter, who is of the same party. The number of persons engaged is properly eleven on each side. As in single wicket, the game is determined by the number of runs made in two *innings* by each player; the party gaining the greater number of runs being victor.

Such is an outline of the two kinds of the game; but there are many minute differences in playing in different parts of England, which it would be tedious to describe. It has been conceded by general consent to follow, in case of dispute, the laws and regulations of the 'Mary-le-bone Cricket Club,' an association in London which has taken a leading part in this truly English sport. The following are the laws and regulations of this club:—

### Laws and Regulations of Single Wicket.

1. When there shall be fewer than five players on a side, bounds shall be placed, at twenty-two yards each, in a line from the off and leg-stump.
2. The ball must be hit before the bounds to entitle the striker to a run; which run cannot be obtained unless he touch the bowling-stump or crease in a line with it with his bat or some part of his person, or go beyond them; returning to the popping-crease, as at double wicket, according to the twenty-second law.
3. When the striker shall hit the ball, one of his feet must be on the ground, and behind the popping-crease, otherwise the umpire shall call "No hit."
4. When there shall be less than five players on a side, neither byes nor overthrows shall be allowed; nor shall the striker be caught out behind wicket, nor stumped out.
5. The fieldsmen must return the ball, so that it shall cross the play between the wicket and the bowling-stump, or between the bowling-stump and the bounds. The striker may run till the ball be so returned.
6. A for the striker has made one run, he must touch the bowling-stump and turn, before the ball shall cross the play, to entitle him to another.
7. The striker shall be entitled to three runs for lost ball, and the same number for ball stopped with hat, with reference to the twenty-ninth and thirty-fourth law of double wicket.
8. When there shall be more than four players on a side, there shall be no bounds. All hits, byes, and overthrows will then be allowed.
9. The bowler is subject to the same laws as at double wicket.
10. Not more than one minute shall be allowed between each ball.

### Laws and Regulations of Double Wicket.

1. The ball must not weigh less than five ounces and a-half, nor more than five ounces and three-quarters. It must not measure less than nine inches, nor more than nine inches and one-eighth, in circumference. At the beginning of each *innings*, either party may call for a new ball. (But in matches, the same ball must go through the game.)
2. The bat must not exceed four inches and one-quarter in the widest part; it must not be more than thirty-eight inches in length.
3. The stumps, three to each wicket, must be twenty-seven inches out of the ground, the balls eight in length; the stumps of sufficient thickness to prevent the ball from passing through.
4. The bowling-crease must be in a line with the stumps, six feet eight inches in length; the stumps in the centre, with a return crease at each end towards the bowler, at right angles.

5. The popping-crease must be four feet four inches from the wicket, and parallel to it; unlimited in length, but not shorter than the bowling-crease.
6. The wickets must be pitched opposite to each other by the umpires, at a distance of twenty-two yards.
7. It shall not be lawful for either party during a match, without the consent of the other, to alter the ground by rolling, watering, covering, mowing, or beating. This rule is not meant to prevent the striker from beating the ground with his bat near to the spot where he stands during the *innings*, nor to prevent the bowler from filling up holes with saw-dust, &c. when the ground shall be wet.
8. After rain, the wickets may be changed, with the consent of both parties.
9. The bowler shall deliver the ball with one foot behind the bowling-crease, and shall bowl four balls before he change wickets, which he shall be permitted to do once only in the same *innings*.
10. The ball must be bowled. If it be thrown or jerked, or if the hand be above the shoulder in the delivery, the umpire must call "No ball." (This is not reckoned as one of the four balls.)
11. The bowler may require the striker at the wicket from which he is bowling to stand on that side of it which he may direct.
12. If the bowler toss the ball over the striker's head, or bowl it so wide that it shall be out of distance to be played at, the umpire (even though he attempt to hit) shall adjudge one run to the parties receiving the *innings*, either with or without an appeal from them, which shall be put down to the score of wide balls, and such ball shall not be reckoned as any of the four balls. When the umpire shall have called "Wide ball," one run only shall be reckoned, and the ball shall be considered dead.
13. If the bowler shall deliver a "No ball," the striker may play at it, and be allowed as many runs as he can get; and he shall not be put out except by running out. In the event of no run being obtained by any other means, then one run shall be scored.
14. In the event of a change of bowling, no more than two balls shall be allowed for the sake of practice.
15. If the bowler bowl one ball, he shall be obliged to bowl four.
16. The striker is out if either of the balls be bowled off, or if a stump be bowled out of the ground.
17. Or if the ball, from a stroke of the bat or hand below the wrist, be held before it touch the ground, although it be hugged to the body of the catcher.
18. Or if in striking, or at any other time while the ball is in play, both his feet be over the popping-crease, and his wicket put down, except his bat be grounded within it.
19. Or if in striking at the ball he hit down his wicket.
20. Or if, under pretence of running or otherwise, either of the strikers prevent a ball from being caught, the striker of the ball is out.
21. Or if the ball be struck, and he wilfully strike it again.
22. Or if, in running, the wicket be struck down by a throw or by the hand or arm (with ball in hand) before his bat (in hand) or some part of his person be grounded over his popping-crease. But if the balls be off, a stump must be struck out of the ground.
23. Or if any part of the striker's dress knock down the wicket when striking.
24. Or if the striker touch or take up the ball while in play, unless at the request of the opposite party.
25. Or if with any part of his person he stop the ball, which in the opinion of the umpire at the bowler's wicket shall have been delivered in a straight line to the striker's wicket, and would have hit it.
26. If the players have crossed each other, he that runs for the wicket which is put down is out.
27. A ball being caught, no run shall be reckoned.
28. If a "Lost ball" be called, the striker shall be allowed six runs; but if more than six shall have been run before "Lost ball" shall have been called, then the striker shall have all which shall have been run.
29. After the ball shall have been lodged and definitively settled in the wicket-keeper's or bowler's hand, it shall be considered dead. If, when the bowler is about to deliver the ball, the striker at his wicket shall go outside his popping-crease before such actual delivery, the said bowler may put him out.
30. If the striker be hurt, he may retire from his wicket, and return to it at any time during that *innings*.
31. If a striker be hurt, some other person may stand out for him, but not go in.
32. No substitute in the field shall be allowed to bowl, keep wicket, stand at point, cover the point, or stop behind in any case.
33. If any fieldsmen stop the ball with his hat, the ball shall be considered dead, and the opposite party shall add five runs to their score. If any be run, they shall have five in all.
34. The ball having been hit, the striker may guard his wicket with his bat, or with any part of his body, except his hand; but the twenty-fourth law, by which he is forbidden to touch or take up the ball, may not be disobeyed.
35. The wicket-keeper shall not take the ball for the purpose of stumping until it has passed the wicket. He shall stand at a reasonable distance behind the wicket, and shall not move till the ball be out of the bowler's hand; he shall not by any noise incommode the striker; and if any part of his person be over or

## OUT-OF-DOOR RECREATIONS.

before the wicket, although the ball hit it, the striker shall not be out.

36. The umpires shall not stand more than six yards from the wicket; they are sole judges of fair and unfair play, and all disputes shall be determined by them, each at his own wicket; but in case of a catch which the umpire at the wicket bowled from cannot see sufficiently to decide upon, he may apply to the other umpire, whose opinion shall be conclusive.

37. The umpires in all matches shall pitch fair wickets, and the parties shall toss up for the choice of innings.

38. They shall allow two minutes for the striker to come in, and fifteen minutes between each innings. When the umpire shall call "Play," the party refusing to play shall lose the match.

39. They are not to order a striker-out, unless appealed to by the adversaries.

40. But if one of the bowler's feet be not entirely behind the bowling-crease, within the return-crease, when he shall deliver the ball, the umpire at his wicket, unasked, must call "No ball."

41. If, in running, either of the strikers shall fail to ground his bat (in hand) or some part of his person over the popping-crease, the umpire for every such failure shall deduct two runs from the number intended to have been run; because such striker not having run home in the first instance, cannot have started in the second from the proper goal.

42. No umpire shall be allowed to bet.

43. No umpire is to be changed during a match, unless with the consent of both parties, except in case of a violation of the forty-second law; then either party may dismiss the transgressor.

44. After the delivery of four balls, the umpire shall call "Over," but not until the ball shall be lodged and definitively settled in the wicket-keeper's or bowler's hand; the ball shall then be considered dead. Nevertheless, if an idea be entertained that either of the strikers is out, a question must be put previously to, but not after, the delivery of the next ball.

45. The umpire must take especial care to call "No ball" instantly upon delivery; "Wide ball" as soon as ever it shall pass the striker.

To these laws and regulations it may be of use to add the following diagram, representing the field during a cricket match, with the proper position of the parties playing, also the technical names of these parties:—

Names of parties indicated by the figures:—\*, Strikers; 1, Bowler; 2, Wicket-keeper; 3, Long Stop; 4, Short Slip; 5, Long Slip; 6, Point; 7, Cover; 8, Middle Wicket; 9, Long Field, off side; 10, Long Field, on side; 11, Leg; O, Umpires; ††, Scorers. This is the usual placing of the field-men, but bowlers make such alterations as they deem best to oppose the strikers.

### BOWLS.

Games with bowls are of great antiquity, and have existed in many different forms. That which has ultimately become the proper English game of bowling is performed with balls of fine hard wood on a smooth shaven lawn called a *bowling-green*. There are two parties, and each individual possesses a bowl. One of each party plays alternately. The object is to deliver the ball from the hand along the surface of the green, and in such a manner as to place it close by an appointed mark. The party which first gains the specified number of points, by being nearest the goal, is victor. The goal or object played to is a small ball called the *jack*. It is not fixed upon any particular spot, but is bowled by one of the party to a certain distance.

A bowling-green requires to be remarkably level, and kept closely shaved by the scythe. The length of space played in, called sometimes a *rink*, may be about thirty yards. The balls are not altogether spherical;

they are spheroids, or flattish on two opposite sides. They are usually made of *lignum vitæ*, and are sometimes handsomely mounted with silver plates on the sides, bearing the names or arms of the owners. The size varies from about four to six inches in diameter.

A knowledge of the value of forces, which can be gained only by experience, is necessary in bowling; but a not less important requisite is a knowledge of the art of giving a bias to the bowl. A person skilled in this art will, by a peculiar pressure of the fingers in delivering his ball, cause it to roll in a kind of semicircle, so as to go with a sweep round the cluster of balls in front of the jack, and come to its place of rest close by the jack or goal.

The game is healthful and exhilarating, and played in moderation, seems well adapted for the recreation of sedentary persons. In many towns in England and Scotland there are beautiful bowling-greens, the property of the citizens at large, or maintained by private clubs. In Glasgow there are several bowling clubs, and the following are a few of the regulations laid down for the game by a most respectable association in that city—namely, the 'Wellcroft Bowling Club':—

#### Regulations for Bowls.

'The game to consist of nine points, unless otherwise agreed; and the throwing of the jack and playing first to be decided by lot.

If the jack is thrown into the ditch on any occasion after the first throw, the opposite party have the privilege of throwing it anew, and not afterwards moved if three feet clear of the ditch in front of the players. This rule not to apply to the side ditch, from which the jack must be sufficiently distant to allow both fore and back-hand play.

All players, when throwing their bowl, to have one foot on the aftermost white ball marked on the cloth; the position of the cloth not to be changed during an end; and if by accident removed from its situation, to be placed as near as possible to the same spot.

A bowl touching the jack at any time during its course on the green, is what is called a "toucher," and counts the same as any other bowl, though in the ditch.

If the jack, or bowl, after touching the jack, is run into the ditch, the place where either rests may be marked, the jack placed at the edge of the ditch, and both replaced when the end is played out.

If the jack is *burned*, or displaced otherwise than by the effect of the play, the opposite party to have the option of playing out the end, or beginning it anew.

When a bowl is burned, if belonging to the party guilty, it is to be put off the green; if belonging to the opposite party, to be replaced as near its original position as possible by the party to whom it belongs. If the jack is burned by a non-player, the end to be played over again.

If a bowl is accidentally marred by an opponent, it shall be in the option of the party playing to let it rest, or play it over again; if it is marred willingly by an opponent, it may be placed anywhere, at the pleasure of the player. If a bowl is marred in either case by the player's party, the opponents to have the same privilege.

If a bowl (without touching the jack) rebounds from the ditch, it shall be put off the green; and if it has disturbed either jack or bowls, they shall be replaced as near as possible by the opponent's party.

After an end is played, neither jack nor bowls to be touched until the game is counted and all parties satisfied. And no measuring till the end is played.

No player to change his bowls during the game; the party doing so loses the game.'

### GOLF.

The game of golf is believed to be peculiar to Scotland, though most likely derived from Germany; the term *golf* being from the German word *halbe*, or the Dutch *kolf*, a club. The popular pronunciation of the Scotch word is *goff*, or *gowf*. Strutt, in his 'Sports and Pastimes of the People of England,' observes that 'there are many games played with the ball, that require the assistance of a club or bat, and probably the most ancient among them is the pastime now distinguished by the name of goff. In the northern part of the kingdom goff is much practised. It answers to a rustic pastime of the Romans, which they played with a ball of leather stuffed with feathers, and the goff-ball is composed of the same materials to this day. During the reign of Edward III., the Latin name *cambuca* was applied to this pastime, and it derived the denomi-

nation, no doubt, from the crooked club or bat with which it was played.'

It seems to be quite uncertain at what period the game of golf was introduced into Scotland; but it may be fairly presumed that this amusement, as well as football and archery, were practised to a considerable extent in the reign of our King James I.

King Charles I. was much attached to the amusement of golfing, and on his visit to Scotland in 1641, was engaged in it on Leith Links when intimation was given him of the rebellion in Ireland; whereupon he threw down his club, and returned in great agitation to Holyrood House. The Duke of York, afterwards James II., also delighted in the game.

Golf is played upon a large piece of open ground, covered with short herbage, but not necessarily level. It is considered that skill is best shown by playing over a surface on which there are certain irregularities or *hasards*. The grounds on which the game is played are called *links*—a term nearly equivalent to downs in England. The open downs of Blackheath, near Greenwich, seem a fair specimen of the kind of ground suitable for the sport, and there we believe it is now played. Brunsfield Links, a small common near Edinburgh, slope somewhat, and are irregular in form, but they afford a fine opportunity of showing skill in playing 'up and down the green,' a greater force being required in strokes in impelling the ball in one direction than in another. Undoubtedly the finest golfing ground in the kingdom is the Links of St Andrews, extending about three miles in length, and presenting all those irregularities which add interest and zest to what might otherwise be considered a tame and dull recreation. Perth, Musselburgh, North Berwick, Leven, and several other places in Scotland, are also in possession of capital golfing grounds.

Golf is entitled to be called a 'respectable' game. It is played almost exclusively by gentlemen, and is conducted leisurely, and without any appearance of boisterousness. A stranger would call it a spiritless sport—little better than walking. It possesses, however, the usual fascination of a game of skill and chance, and might appropriately be compared to billiards—the table being a green of a mile in length, the billiard rods clubs, the balls, instead of ivory, hard-stuffed leather, and the purses holes in the ground.

Golfs are formed of wood. The handle, which is straight, is generally about four and a-half feet long, and made of ash or hickory. To the lower part of this stalk is united, by compact tying, a flattish-curved end, which is the striking part; it is faced with horn, and to give force, is loaded with lead. To give a hold to the hands, the upper extremity of the stalk is wrapped with a rind of cloth. In regular practice, players use several golfs. Each has his set of three, four, five, or even as many as ten, which is carried by an attendant boy called a *caddie*; and from this set the golf appropriate for the stroke is selected. Sometimes the ball lies fairly on the grass, at other times it may have got into a hollow, or behind a stone or bush, and an instrument best adapted for sending it forward, or lifting it from its *hasard* or awkward situation, is in requisition. One of the golfs is technically called the *spoon*, from its use in lifting the ball from hollows; another is called the *iron*; and so on.

The ball is small, being not more than an inch and a-half in diameter; it is made of thick prepared hide, stuffed almost as hard as a stone with feathers; the outside is smooth, and painted white. At Edinburgh, St Andrews, and Musselburgh, the making of golfs and balls is a regular profession.

There are generally two players, one matched against the other. Each has his own ball. The game consists in driving the ball into certain holes made in the ground, which he who achieves in the fewest strokes obtains the victory. When four persons play, two of them are sometimes partners, and have but one ball, which they strike alternately. The holes are situated at the different ends and sides of the green, at irregular distances,

and their number is optional. The usual number is five. A player must never touch his ball, unless in very particular circumstances, or when he takes it out of one of the holes. When commencing from a hole, the ball may be copped up on the point of a dot of mud or turf, to allow of a commanding stroke; and this is called *teeing* the ball; but on all other occasions the ball must be struck or impelled by the golf from the place in which it happens to lie. Much depends on the first blow, and it should be given with great firmness of person and a good aim. Properly performed, the first stroke will send the ball two hundred yards, while at other times a blow in an awkward situation will advance it only a few feet. When the balls at length get near a hole, great skill is shown in *putting* or giving those delicate strokes which will not make the ball go beyond the hole, but, if possible, into it. A knowledge of the value of forces, the nature of the green, the influence of wind or weather, &c. is important in this and all other parts of the game, and is only to be gained by long experience.

At Edinburgh, Leith, Musselburgh, St Andrews (which may be considered as the head-quarters of golfing), Perth, and some other towns, there are associations or clubs of golfers, whose proceedings are governed by certain laws and regulations. The oldest in Edinburgh are the 'Edinburgh Burgess' and 'Bruntsfield Links' Golfing Societies. The Brunsfield Links Society was instituted in 1761, and is limited to forty members, the uniform of which is declared 'to be a red jacket with green velvet collar and badge, bearing the arms of the society—namely, vert two golf clubs in saltier, with heads in chief proper, between four golf-balls argent: motto in an escroll below the shield, *Inde Satus* (Thence Health). The affairs of the society are managed by a captain, treasurer, secretary, and six councillors, elected annually. A gold medal, played for annually on the last Saturday of March, is retained by the winner for one year. A silver medal, played for annually on the last Saturday of September, is retained by the winner as his property. The following are the regulations prescribed by the society for playing the game; and which may be held as generally applicable:—

1. No golfer, or caddie, to be allowed to dig tee within ten yards of the hole, and no ball to be teed nearer the hole than two club-lengths, nor farther from it than four, unless by consent of parties, and the ball to be teed on the ground.
2. Two or more parties meeting at the hole, the party who plays first to be allowed to play their second strokes before the succeeding party strikes off. But should the first parties' ball be in a hazard, that party shall allow the second party to pass.
3. Every hole must be played out with the same ball that is struck from the tee.
4. All loose sticks, stones, filth, nuisance, or other movable impediments, may be removed, if within one club-length of the ball; and in putting, all movable obstructions may be removed within four club-lengths of the hole—the distance to be measured with the club which the party is to play with. In the event of a ball getting into a hole, or any other hazard, the party shall be allowed to take it out, and standing immediately behind the hazard, drop it over his shoulder, and play it, losing a stroke.
5. No hole is gained unless the ball be holed (except by consent of parties), and a party losing his ball loses the hole.
6. In case of doubt as to the ball belonging to either party, neither ball shall be lifted unless by consent of parties, and the ball farthest from the hole must be played first.
7. If a ball be struck or moved by any one not of the party, it shall be brought back and played from where it was so struck or moved, the party previously dropping it over his shoulder.
8. In a match of more than two players, if a ball be struck twice or oftener, successively by one player, that side of the match loses the hole.
9. If a party play the adversary's ball, the adversary gains the hole.

## OUT-OF-DOOR RECREATIONS.

10. If a party personally, or by his caddie, stop or touch any ball of the match, the adversary gains the hole.
11. If a ball stick fast into the ground, it may be loosened.
12. In playing for prizes, no competition to be allowed unless the parties be dressed in the uniform of the society.
13. In putting, the ball, if practicable, shall be played directly for the hole, but if the adversary's ball oppose the player, it shall be lawful to play upon it.

Enthusiastic and long-experienced cultivators of golf at Edinburgh have been known to perform some remarkable feats in their favourite sport. 'Bets of a novel nature, which set the ordinary routine of the game entirely aside, are occasionally undertaken by the more athletic. An amusing and difficult feat, sometimes attempted from Bruntsfield Links, is that of driving the ball to the top of Arthur's Seat [a hill 800 feet high]. In this fatiguing undertaking, being a species of steeple-chase over hedges and ditches, the parties are usually followed by bottle-holders and other attendants, denoting the excessive exertion required. In 1798, bets were taken in the Burgess Golfing Society that no two members could be found capable of driving a ball over the spire of St Giles's steeple. The late Mr Scales of Leith, and the present Mr Smellie, printer, were selected to perform this formidable undertaking. They were allowed to use six balls each. The balls passed considerably higher than the weather-cock, and were found nearly opposite the Advocate's Close. The bet was decided early in the morning, in case of accident, the parties taking their station at the south-east corner of the Parliament Square. The feat is described as one of easy performance. The required elevation was obtained by a barrel-stave suitably fixed; and the height of the steeple, which is one hundred and sixty-one feet, together with the distance from the base of the church, were found to be much less than a good stroke of the club."

### SHINTY—HURLING.

Shinty in Scotland, Hockey in England, and Hurling in Ireland, appear to be very much the same out-of-door sport. We shall describe shinty:—Two parties armed with sticks or clubs crooked at the lower extremity, and generally termed *gowffs* (golfs), throw down a little ball of wood, called a *shinty*, midway between two points, and the struggle is, which party will drive the ball to their 'hail,' as it is called, or the point allotted as their goal. It may be guessed by those who have never seen it, that there is smart smashing work at this game of shinty—most appropriately named so, seeing that the shins of the players are exposed to ticklish cracks from the clubs of their opponents when a lock takes place, and a dozen boys, perhaps, are struggling to get the ball out from among each other's feet. Hard though the ball be, and smart the strokes given, the activity and quick eyes of the players usually prevent any great injury from being received at shinty. By far the most serious mischief commonly resulting from it consists in the damage which it brings upon the neighbouring hawthorn hedges, which are sadly cut to pieces in order to provide clubs for the sport. The worst of it is that young hawthorn slips, with the root cut for the striking part, make by far the best clubs, and accordingly the evil done is radically ruinous to the unfortunate hedgerows.

Hurling is alluded to as follows by Mr and Mrs Hall, in their work on Ireland:—"The great game in Kerry, and indeed throughout the South, is the game of "Hurley"—a game rather rare, although not unknown, in England. It is a fine manly exercise, with enough of danger to produce excitement, and is, indeed, *par excellence*, the game of the peasantry of Ireland. To be an expert hurler, a man must possess athletic powers of no ordinary character; he must have a quick eye, a ready hand, and a strong arm; he must be a good runner, a skilful wrestler, and withal patient as well as resolute. In some respects it resembles cricket; but the rules and the form of the bats

are altogether different; the bat of the cricketer being straight, and that of the hurler crooked.

The forms of the game are these:—The players, sometimes to the number of fifty or sixty, being chosen for each side, they are arranged (usually barefoot) in two opposing ranks, with their hurleys crossed, to await the tossing up of the ball, the wickets or goals being previously fixed at the extremities of the hurling-green, which, from the nature of the play, is required to be a level extensive plain. Then there are two picked men chosen to keep the goal on each side, over whom the opposing party places equally tried men as a counterpoise; the duty of these goal-keepers being to arrest the ball in case of its near approach to that station, and return it back towards that of the opposite party, while those placed over them exert all their energies to drive it through the wicket. All preliminaries being adjusted, the leaders take their places in the centre. A person is chosen to throw up the ball, which is done as straight as possible, when the whole party, withdrawing their hurleys, stand with them elevated, to receive and strike it in its descent; now comes the crash of mimic war—hurleys rattle against hurleys—the ball is struck and restruct, often for several minutes, without advancing much nearer to either goal; and when some one is lucky enough to get a clear "puck" at it, it is sent flying over the field. It is now followed by the entire party at their utmost speed; the men grapple, wrestle, and toss each other with amazing agility, neither victor nor vanquished waiting to take breath, but following the course of the rolling and flying prize; the best runners watch each other, and keep almost shoulder to shoulder through the play, and the best wrestlers keep as close on them as possible, to arrest or impede their progress. The ball must not be taken from the ground by the hand; and the tact and skill shown in taking it on the point of the hurley, and running with it half the length of the field, and, when too closely pressed, striking it towards the goal, is a matter of astonishment to those who are but slightly acquainted with the play. At the goal is the chief brunt of the battle. The goal-keepers receive the prize, and are opposed by those set over them: the struggle is tremendous—every power of strength and skill is exerted; while the parties from opposite sides of the field run at full speed to support their men engaged in the conflict; then the tossing and straining are at their height, the men often lying in dozens side by side on the grass, while the ball is returned by some strong arm again, flying above their heads, towards the other goal. Thus for hours has the contention been carried on, and frequently the darkness of night arrests the game without giving victory to either side. It is often attended with dangerous, and sometimes with fatal results.

Matches are made sometimes between different townlands or parishes, sometimes by barony against barony, and not unfrequently county against county; when the "crack men" from the most distant parts are selected, and the interest excited is proportionably great. About half a century ago, there was a great match played in the Phoenix Park, Dublin, between the Munster men and the men of Leinster. It was got up by the then lord-lieutenant and other sporting noblemen, and was attended by all the nobility and gentry belonging to the vice-regal court, and the beauty and fashion of the Irish capital and its vicinity. The victory was contended for a long time with varied success; and at last it was decided in favour of the Munster men, by one of that party running with the ball on the point of his hurley, and striking it through the open windows of the vice-regal carriage, and by that manœuvre baffling the vigilance of the Leinster goalmen, and driving it in triumph through the goal. This man is still living; his name is Mat. Healy, and he has been many years a resident in London. Between twenty-five and thirty years ago, there were several good matches played on Kennington Common, between the men of St Giles's and those of the eastern parts of the

\* Biographical sketches of 'Kay's Portraits.'

metropolis; the affair being got up by the then notorious Lord Barrymore and other noblemen who led the sporting circles of the time.'

FIVES—RACKETS—TENNIS.

The sport of striking a soft ball covered with leather against a wall, or throwing it upwards and catching it with the hand, seems to be of great antiquity, and in progress of time was regulated into the character of certain games. One of these, the most simple of the whole, is the striking of a ball against a wall, rebounding from which it falls with force on the ground, and in the rise is again struck in the same manner. The sustaining of this action for a specified number of times constitutes the game. In England it has been customary to call a game of this kind *fives*, from the ball being struck with the five fingers and palm of the hand. In Scotland it has for ages been called *oage* or *caitch*-ball. James I., in his quaint production descriptive of what should constitute the education and recreations of a prince, refers to catch-ball. He remarks—'The exercises I would have you to use, although but moderately, not making a craft of them, are running, leaping, wrestling, fencing, dancing, and playing at the *caitch* or tennis, archerie, palle-malle, and such-like other fair and pleasant field-sports.'

*Rackets* is the same game as *fives*; but instead of striking the ball with the open hand, it is struck by a racket, which is an implement held in the hand formed of a frame and catgut. It is played against a high and broad wall, even in surface, with a smooth stone or earthen ground, from which the ball will rise evenly to the hand. Two persons play the match, each striking the ball alternately, and each strikes it in such a way as that his adversary may not be able to return it. But the adversary is supple of limb and quick of eye; and darting to the spot on which the ball is about to fall, endeavours to strike it with his racket, and preserve it from rolling on the ground. He who does not return the ball, either loses a point (or, as it is termed, an *ace*) or has his *hand out*—that is, forfeits the situation in which he would be able to add to his score of the game. Neither *fives* nor *rackets* are now played to the extent that they formerly were. There are still, however, several courts laid out for these games in the metropolis; and nowhere are they played so well as in the courtyards of the Queen's Bench and Fleet prisons, where many of the inmates endeavour to kill time by this species of amusement.

*Tennis* is a game similar with ball; it is played with a racket; but instead of striking the ball against a wall, it is struck over a central net, on each side of which the players stand. The game, which was once fashionable, we believe, is now scarcely ever practised.

TRAP-BALL.

This game, which is traceable as far back as the commencement of the fourteenth century, is played chiefly by boys. A wooden object called a 'trap,' resembling a shoe in shape, with a spring slip or tongue fastened in it by a joint, is laid on the ground. The ball is laid on one end of the spring; the other end is struck with a bat, and the ball rising is to be smartly struck. 'It is usual,' says Strutt, 'in the present game of trap-ball, when properly played, to place two boundaries at a given distance from the trap, between which it is necessary for the ball to pass when it is struck by the batsman; for if it falls withoutside of either, he gives up his bat, and is out; he is also out if he strikes the ball into the air and it is caught by one of his adversaries before it grounds; and again, if the ball, when returned by the opposing party, touches the trap, or rests within one bat's length of it; on the contrary, if none of these things happen, every stroke tells for one towards the striker's game.' In some country parts of England trap-ball is still a favourite sport.

FOOT-BALL.

Foot-ball is an old English sport, now little known

in some parts of the country, but keenly played in others. It is played by means of a distended ox-bladder, tightly covered with dressed leather, and sewed up in a strong and secure way, so as to retain its full elasticity. This ball is thrown aloft in the air betwixt two parties of players, equidistant from each other; on one side and the other there is a fixed point or line called, as in the preceding case, the hail or hailing spot. The object, then, of each party is, by vigorous kicks, to propel the ball to the hailing-place behind their adversaries, on the attainment of which object the game is won. This game is less hazardous than shinty, and exercises fully both the strength and speed of the players. It is amazing how dexterous even very young boys become by continual practice at foot-ball; and skill in the application of a slight degree of force avails much more at this sport than greater strength unskilfully directed. The young men of the Scottish Border yet practise this game annually in various places; and few sights can be more exhilarating than to behold a strong body of them so employed, when the fleet foot of the shepherd vies for conquest with the vigour of the ploughman, and health and enjoyment beam unequivocally from every countenance.

QUOITS.

Contests in throwing or pitching heavy pieces of metal were practised by the ancient Greeks at their great periodical assemblages for athletic exercises. The piece of metal thrown was called the *discus*, from its round form. The main object in these contests was the cultivation of strength of arm, and victory was gained more from the ability of throwing heavy weights to a distance than from skill in attaining a particular mark.

From these ancient practices, first pursued by the Greeks, and then by the Romans, the game of quoits, or coits, appears to have been derived. The quoit is a circular plate of iron perforated in the middle, or, more properly, a flattish iron ring, concave on one side, and convex on the other, the concave or hollow side being undermost in throwing; and a notch being in the edge for the finger to press upon in delivering the throw. Quoits are of different sizes, to suit the different tastes and powers of players. 'To play at this game,' says Strutt, 'an iron pin called a "hob" is driven into the ground within a few inches of the top: and at the distance of eighteen, twenty, or more yards (for the distance is optional), a second pin of iron is also made fast in a similar manner; two or more persons, as four, six, eight, or more, at pleasure—who, divided into two equal parties, are to contend for the victory—stand at one of the iron marks, and throw an equal number of quoits at the other [the quoit being delivered from the hand by an upward and forward pitch with a steady aim at the pin, near which it should sink with its sharp edge in the turf]; the nearest of them to the hob are reckoned towards the game. But the determination is discriminately made: for instance, if a quoit belonging to A lies nearest to the hob, and a quoit belonging to B the second, A can claim but one towards the game, though all his other quoits lie nearer to the mark than all the other quoits of B; because one quoit of B being the second nearest to the hob, *cuts out*, as it is called, all behind it; if no such quoit had interfered, then A would have reckoned all his as one each. Having cast all their quoits, the candidates walk to the opposite end and determine the state of the play; then, taking their stand there, throw their quoits back again, and continue to do so alternately as long as the game remains undecided.' The dress in quaiting should be loose and easy, with no restraint from braces.

In some of the rural districts of England horse-shoes used to be employed as quoits; and in some parts of Scotland the quoits consist of round flat stones, games with which are called the 'penny-stanes.'

# IN-DOOR AMUSEMENTS.

## CHESS.

It has been justly observed, that among all the in-door amusements invented by man for the employment of the idle or the relief of the studious, chess stands pre-eminent. It is the most refined and ingenious of all games, and possesses a charm which has rendered it a favourite of the greatest characters, whether kings, warriors, or philosophers. As an amusement, it possesses an advantage as great as it is singular; being highly interesting in itself, and played with leisure, it requires no inducement of gain, and in consequence is rarely played for money. The glory of conquest is allowed to form a sufficient attraction.

Chess is of unknown origin and antiquity. Some writers have ascribed its invention to the Greeks, some to the Hindoos, others to the Chinese, and a fourth class to the Persians. There can be little doubt that it originated in the East, and at a very remote period of history; and it is certain that it has been known in Hindoostan and adjacent regions for at least two thousand years. From the Persians it was introduced by the Arabs or Moors into Spain; thence it found its way to France; and was made known in England during the reign of William the Conqueror, since which period it has been constantly played.

The name of the game, and also the names of the pieces with which it is played, have undergone many mutations in travelling from country to country; nevertheless, in the present terms which we employ, the semblance of the original Eastern appellations may be seen. In Hindoostan, it possesses the Sanscrit name of *Chaturanga*, which imports the four members of an army—elephants, horses, chariots, and foot-soldiers; the game being a scene of mimic warfare, in which these elements respectively act a peculiar part. The Persians corrupted the Sanscrit word into *chatrang*, which the Arabians softened into *shatranj*; from that appellation it passed into *scacchi*, *échecs*, and finally chess. By the French it is called *échecs*, and a chess-board they term *échiquier*.

According to the modern European arrangement, the idea of elephants, horses, chariots, and foot-soldiers has been abandoned, and there have been substituted a king, queen, bishops, knights, castles or rooks, and pawns, forming six distinct classes of pieces. The term *bishop* is only English, being a substitution for elephant. The knights represent the horse-soldiers. The term *rook* is from the Eastern word *rokh*, a hero, and represents an armed chariot or fortification; the English give the piece the form of a castle. The pawns are the foot-soldiers, the name being from *peon*, an attendant.

The chess pieces made in India or China for sale to wealthy Europeans, are sometimes made of solid ivory, five or six inches high, and are exceedingly beautiful, no degree of labour being spared in the carving. The king and queen are seated on elephants, under a canopy; the bishops are camels, with archers as their riders; the knights are on horseback; the castles are elephants, with castles on their backs filled with warriors; and the pawns are soldiers, one a sergeant, another a drummer, another a fifer, and the rest are the ordinary fighting men. In England the pieces are usually made of bone or boxwood, with more or less taste, and from a low to a high price. The following is their common form:—

### Chess Men and Board.

There are two sets of pieces, of different colours; the one usually white, and the other red. A set consists of sixteen pieces, so that the entire number with which the game is played is thirty-two pieces. A set includes one king, one queen, two bishops, two knights, two rooks or castles, and eight pawns. Two parties play, each having a set of a different colour.

1	2	3	4	5	6	7	8
9	10	11	12	13	14	15	16
17	18	19	20	21	22	23	24
25	26	27	28	29	30	31	32
33	34	35	36	37	38	39	40
41	42	43	44	45	46	47	48
49	50	51	52	53	54	55	56
57	58	59	60	61	62	63	64

The game is played on a square board, divided into sixty-four squares, chequered black and white, as represented in the preceding figure. The numbers which are here shown on the squares do not exist on the chess-board; we have only marked them thus in order to illustrate the subjoined explanations of the method of playing the game.

In beginning to play the game, the first thing is to set the board. This is done by placing it before you, with a white square in the right-hand corner. As the players sit opposite each other at a table on which the board is placed, each has a white square on his right.

Next place the men in their appointed places. Let us suppose it is the white set of men. On the white corner square marked 64 place a rook or castle, and on the black corner, 57, place the other rook; on the black square, 63, place a knight, and on the white square, 58, place the other knight; on the white square, 62, place a bishop, and on the black square, 59, place the other bishop; on the black square, 61, place the king, and on the white square, 60, place the queen. This completes the first row, in which the king and queen stand supported on each side by their officers. The second row, marked 49, 50, 51, 52, 53, 54, 55, 56, is filled entirely with the eight pawns, which thus form a front guard to the pieces behind.

The red or dark set of pieces are placed in precisely the same order—a castle on 1 and 8, a knight on 2 and 7, a bishop on 3 and 6, the queen on 4, and the king on 5. It is a rule of the game that the queen must be placed at first on a square of her own colour—the white queen on a white square, and the dark queen on a dark square. The pieces and pawns on the side and front of each king and queen take their names from them; as king's bishop, king's knight; queen's bishop, queen's knight; king's pawn, &c.

When properly placed, four rows of squares are left unoccupied in the middle of the board, and this space forms the field or ground on which the early evolutions of the men take place.

The Moves.

It is a leading peculiarity of chess that each class of pieces has its own peculiar value and style of moving; some can move one way and some another, a system very different from that of the ordinary movements on a draught board.

A *pawn* moves only one square at a time, in a straight line forward, and takes the enemy diagonally. On being first moved, however, a pawn has the power of advancing either one square or two, as the player thinks fit, unless the square over which he leaps is commanded by a hostile pawn; so that if he were to rest on that square instead of leaping over it, he might be captured. In such a case the adverse pawn has the option of taking him, and placing himself on the square leaped over. A pawn cannot move backwards; but on getting to the further side of the board, upon the first line of the enemy, which is styled *going to queen*, he may be changed for any one of the pieces lost in the course of the game, and the piece chosen must be placed on the square at which the pawn has arrived. If not exchanged, he remains idle. The power of taking diagonally, possessed by a pawn, differs from that of all other pieces, who take in the direction in which they move: after every capture he continues to go forward as before. The king's bishop's pawn is reckoned the most valuable.

A *knight* moves obliquely, either backward or forward, upon every third square, including the square on which he stood; from black to white, or white to black, over the heads of the men, which no other piece is permitted to do. For example, a knight may leap from 36 to 19, 21, 26, 30, 42, 46, 51, or 53, passing over pieces in the intermediate squares. This property of leaping renders the knight particularly useful at the beginning of a game, as he can be brought into the enemy's ranks, and retire, notwithstanding any blockade; and should he check a king, without being himself liable to be taken, the king must remove, and cannot afterwards castle.

The *bishop* moves only diagonally over any number of squares, as far as they are open, forward or backward, but always on the colour he is first placed on. He can take at any distance when the road is open. For example, the bishop may move from 29 to 2, 8, 56, or 57. The king's bishop is usually considered the better one, as he can check the king on his original square, which the queen's bishop cannot.

The *rook* moves backward, forward, or sidewise, and as far as the squares are open. He is viewed as not very useful at the beginning of a game, but is particularly so towards the conclusion, by possessing the power of giving *checkmate* with the king alone, which neither the bishop nor knight can do.

The *queen* is the best piece on the board. She unites the powers of the bishop and rook, and her moves are therefore unlimited, provided the squares are open in her line of motion. As an example, she may be moved from 37 to 1, 5, 16, 23, 40, 58, 61, 64, or any other number in the direction of these, so that the squares are not blocked up. The preservation of the queen is always a matter of great importance in the game.

The *king* moves only one square at a time, but in any direction, either forward or backward, sideways or diagonally. But once in a game, he can move two squares to the right or left, which is termed *castling*. He can take any of the enemy's men in any square adjoining to him, provided he does not place himself in check. This *check* is a peculiarity in his condition. He has the privilege of never being taken; but this can scarcely be considered a benefit, since it only means that he must not move into or continue in a situation of danger. To be in such a situation, and liable to be captured if he were an ordinary piece, is called being in *check*. On the avoidance of this perilous situation the whole game depends; for the instant the king is checkmated, without the means of moving into a place

of safety, the game is at an end. The adversary has the victory.\*

To the foregoing account of the moves and powers of the respective pieces, may be added the following explanation of terms:—

*Castling*.—This, as above hinted at, is allowed once in the course of a game: it consists in moving the king to the second square to the right or left of that where he originally stood, and placing the castle or rook on the square over which he leaped. Castling is a means adopted to secure the king from attack; but it is not allowable—1. When the king or the rook with which you would castle has already been moved; 2. When the king is in check; 3. When the king would require to pass over a square in which he would be checked; and 4. When the king has a piece between himself and the rook.

*Check*.—When the king is in a situation that, were he an inferior piece, he would be taken, notice is given by the adversary, by saying the word '*check*,' and the player must adopt some means of removing him from this position.

*Double check* is when the king is in check by two pieces at once. He may emancipate himself from single or double check—1. By capturing the piece which is attacking him, either by himself or one of his party—and this is only available in double check, if one of the pieces does not guard the other; 2. By interposing a piece between him and the attacking piece; and 3. By removing to another square, of which no hostile piece has the command.

*Checkmate* is when no means of escape or conquest is available; the king is then said to be checkmated, and the game terminates. One king cannot give check to another, as it would place him in a similar situation. The term *checkmate* is said to be a corruption of the Eastern words *chah-mat* (the king is dead).

*Stale-mate* (from *stall*, a place of fixture) is applied to the condition of the king when he is compelled to remain in his place, by being surrounded in such a manner by his own or his adversary's pieces, that he could not move without going into check, and has at the same time no means of moving other pieces. The game is then considered *drawn*—that is, not won by either party.

Laws of Chess.

The game commences by the two parties determining by lot, or concession, which shall have the first move. After this the moves are taken alternately, one piece at a time. The principle of advance is to push forward the men gradually against those of the enemy, each party calculating beforehand what will be the effect of any particular move. The following are old-established laws in reference to playing:—

1. If you touch your man you must play it, except it would expose your king to check, in which case you can only move the king, if it be practicable.
2. As long as you retain a hold of your man, you are at liberty to place him where you think proper, though you may have him set down on a square.
3. If you have removed your hand from a man, he must remain where he is.
4. If you touch one of your adversary's men, he may insist on your taking it if you can; and when you cannot, then you must move your king, provided the move do not put him in check.
5. If you make a false move, by accident or otherwise, your adversary can oblige you to move the king; but if he plays without having noticed the false move, it cannot be recalled.
6. If your adversary challenge you with a check, while in reality the king is not in check, and you move your king or any other

\* In a battle between the French and English, in the year 1117, an English knight seizing the bride of Louis le Gros, and crying to his comrades, 'The king is taken!' the prince struck him to the ground with his sword, saying, 'Ne saés tu pas qu'aux échecs on ne prend pas le roi?'—('Dost thou not know that at chess the king is never taken?') The meaning of which is, that at the game of chess, when the king is reduced to that pass that there is no way for him to escape, the game ends; because the royal piece is not to be exposed to an imaginary affront.—*Philidor on Chess.*

man in consequence, you may retract it if you discover the error before he has made his next move.

7. You are not to give check to your adversary's king, when, by doing so, you would expose your own king to check.

8. If your adversary give check, but without giving the usual warning of 'check,' you are not obliged to notice it till he does; but if he discover that he should have done so on his next move, and then warn you, each must retract his move, and the king be removed out of check or protected.

9. After your king or rook has moved, you cannot castle.

10. In each fresh game the players have the first move alternately; but if a player give the advantage of a piece—that is, agrees to start with one piece less than his antagonist—he who gives the advantage has the first move.

#### Hoyle's Rules for Chess.\*

1. Move your pawns before your pieces, and afterwards bring out the pieces to support them; therefore the king's, queen's, and bishop's pawns should be the first played, in order to open the game well.

2. Do not therefore play out any of your pieces early in the game, because you thereby lose moves, in case your adversary can, by playing a pawn, make them retire, and he also opens his game at the same time; especially avoid playing your queen out, till your game is tolerably well opened.

3. Avoid giving useless checks, and never give any unless to gain some advantage, because you may lose the move if the adversary can either take or drive your piece away.

4. Never crowd your game by having too many pieces together, so as to prevent your men advancing or retreating, as occasion may require.

5. If your game should be crowded, endeavour to free it by exchanges of pieces or pawns, and castle your king as soon as convenient; afterwards bring out your pieces, and attack the adversary where weakest.

6. When the adversary plays out his pieces before his pawns, attack them as soon as you can with your pawns, by which you may crowd his game, and make him lose moves.

7. Never attack the adversary's king without a sufficient force; and if he attack yours, and you cannot retaliate, offer exchanges; and should he retire when you present a piece to exchange, he may lose a move. It may also be sometimes expedient to act in this manner, in case of other attacks.

8. Play your men in guard of one another, so that if any be taken, the enemy may also be captured by that which guarded yours, and endeavour to have as many guards to your piece as your adversary advances others upon; and, if possible, let them be of less value than those he assaults with. When you cannot well support your piece, see if, by attacking one of his that is better, or as good, you may not thereby save yours.

9. Never attack but when well prepared, for thereby you open your adversary's game, and prepare him to pour in a strong attack upon you, as soon as your weaker one is over.

10. Never play till you have examined whether you are free from danger by your adversary's last move; nor offer to attack till you have considered what harm he would be able to do you by his next moves, in consequence of yours.

11. When your attack is in a prosperous way, never be diverted from it by taking any piece, or other seeming advantage your adversary may purposely throw in your way with the intent that, by your taking the bait, he might gain a move which would make your design miscarry.

12. When, in pursuing a well-laid attack, you find it necessary to force your adversary's defence with the loss of some pieces, if, upon counting as many moves forward as you can, you find a prospect of success, sacrifice a piece or two to gain your end: those bold attempts make the finest games.

13. Never let your queen stand so before the king as that your adversary, by bringing forward a rook or a bishop, might check your king if she were not there; for you could hardly save her, or perhaps at best must sacrifice her for an inferior piece; as, for example, place the white king on 61, the queen on 53; the black king on 4, and the rook on 16; which last, if moved to 13, must be taken by the white queen, who, in return, would be taken by the black king, because the white queen could not otherwise be moved without putting the king on check to the black rook.

14. Let not your adversary's knight fork your king and queen, or king and rook, or queen and rook, or your two rooks, at the same time; for, in the two first cases, the king being forced to go out of check, the queen or the rook must be lost; and in the two last, a rook must be lost, at best, for a worse piece. Place the white queen on 5, the rook on 7, and a black knight on 37. The latter piece, if moved to 22, will fork both the queen and rook, and consequently one of them must be lost for the knight.

15. Take care that no guarded pawn of your adversary's fork two of your pieces; knights and rooks are particularly liable to this mode of attack; also guard against either a check by discovery or a stale-mate.

16. When the kings have castled on different sides of the board, attack with the pawn you have on that side where the adversary has castled, advancing the pieces, especially the queen and rooks, to support them; and if the adversary's king have three pawns on a line in front, he should not stir them till forced to it.

\* Hoyle is a very old author, and his works on chess and other games are well known; they are now found in all forms, abridged or altered to suit modern players.

17. Endeavour to have a move in ambuscade; that is, place the queen, bishop, or rook behind a pawn or a piece in such a manner as that, upon playing that pawn or piece, you discover a check upon your adversary's king, and consequently may often get a piece or some other advantage by it. Suppose the black king on 6, a white bishop on 41, and a pawn on 34, by moving the pawn to 26, a check by the white bishop is discovered upon the black king.

18. Never guard an inferior piece or pawn with a better if you can do it with a pawn, because that better piece may in such a case be, as it were, out of play.

19. A pawn pushed on and well supported often costs the adversary a piece; but one separated from the others is seldom of any value. And whenever you have gained a pawn or other advantage, and are not in danger of losing the move thereby, make as frequent exchanges as you can.

20. If each player have three pawns upon the board, and no piece, and you have a pawn on one side of the board, and the other two on the other side, and your adversary's three are opposite to your two, march with your king to take his pawns; and if he move to support them, go on to queen with your single pawn; and if he attempt to hinder it, take his pawns, and push yours to queen; that is, to move a pawn into the adversary's back row, in order to make a queen.

21. At the latter end of the game, each party having only three or four pawns on different sides of the board, the kings are to endeavour to gain the move, in order to win the game; for example, the white king placed on 54, and the black king on 37, white would gain the move by playing to 53, or black to 38, and in both cases the adverse king would be prevented from advancing.

22. When the adversary has no more than his king and one pawn on the board, and you a king only, you can never lose that game if you bring and keep your king opposite to your adversary's, when he is immediately either before or on one side of his pawn, and only one square between the kings. This must, then, be a stale-mate or drawn game.

23. Never cover a check with a piece that a pawn pushed upon it may take, for fear of only getting that pawn for it; put a black rook on 7, and a pawn on 40; the white king on 63, and a knight on 61: the white king being on a check to the rook, if the check be covered by moving the white knight to 55, the black pawn could then be moved to 48, and take the knight.

24. Do not crowd your adversary's king with your pieces, lest you inadvertently give a stale-mate, which is a drawn game.

25. Do not be too much afraid of losing a rook for an inferior piece; though a rook is better than any other except the queen, yet it seldom comes into play so as to operate until the end of the game; and it is generally better to have a worse piece in play than a superior out.

26. When you have moved a piece which your adversary drives away with a pawn, that is a bad move, your enemy gaining a double advantage. At this nice game no move can be indifferent. Though the first move may not be much between equally good players, yet the loss of one or two more, after the first, makes the game almost irremediable; but if you can recover the move or the attack (for they both go together), you are in a fair way of winning.

27. If ever your game be such that you have scarce anything to play, you have either brought out your piece wrong, or, what is worse, not at all; for if you have brought them out right, you must have variety enough.

28. Do not be much afraid of doubling a pawn; two in a direct line are not disadvantageous when surrounded by three or four others; three together are strong (as three white pawns on 29, 35, and 37); but four (as 44 in addition) that make a square with the help of other pieces, well managed, form an invincible strength, and probably may produce you a queen; on the contrary, two pawns, with an interval between (as on 35 and 37), are no better than one; and if you should have three over each other in a line (as 26, 34, and 42), your game cannot be in a worse situation.

29. When a piece is so attacked that it is difficult to save it, give it up, and endeavour to annoy your enemy in another place; for it often happens, that whilst your adversary is pursuing a piece, you either get a pawn or two, or such a situation as ends in his destruction.

30. Supposing your queen and another piece are attacked at the same time, and by removing your queen you must lose the piece, if you can get two pieces in exchange for her, rather do that than retire, for the difference is more than the worth of a queen; besides, you preserve your situation, which is often better than a piece; when the attack and defence are thoroughly formed, if he who plays first be obliged to retire by the person who defends, that generally ends in the loss of the game on the side of him who attacks.

31. Do not aim at exchanges without reason; a good player will take advantage of it to spoil your situation and mend his own; but when you are strongest, especially by a piece, and have not an immediate check-mate in view, then every time you exchange your advantage increases. Again, when you have played a piece, and your adversary opposes one to you, exchange directly, for he wants to remove you: prevent him, and do not lose the move.

32. Every now and then examine your game, and then take your measures accordingly.

33. At the latter end of the game, especially when both queens are off the board, the kings are capital pieces; do not let your

king be idle; it is by his means generally you must get the move and the victory.

34. As the queen, rooks, and bishops operate at a distance, it is not always necessary in your attack to have them near your adversary's king; they do better at a distance, as they cannot be driven away.

35. When there is a piece you can take, and that cannot escape, do not hurry; see where you can make a good move elsewhere, and take the piece at leisure.

36. It is not always right to take your adversary's pawn with your king, for very often it happens to be a safeguard and protection to him. Place a black rook on 5, with a pawn on 45, and the white king on 53, and he will be sheltered by the black pawn from the attack of the rook.

Recommendations as to some of the Foregoing Rules.

1. Whether you play the open or close game, bring out all your pieces into play before you begin the attack; for if you do not, and your adversary should, you will always attack or be attacked at a great disadvantage; this is so essential, that you had better forego an advantage than deviate from it; and no person can ever play well who does not strictly practise this. In order to bring out your pieces properly, push on your pawns first, and support them with your pieces, by which your game will not be crowded, and all your pieces will be at liberty to play and assist each other, and so co-operate towards attaining your end; and either in your attack or defence, bring them out so as not to be driven back again.

2. When you have brought out all your pieces, which you will have done well if you have your choice on which side to castle, then consider thoroughly your own and adversary's game, and not only resolve where to castle, but likewise to attack where you appear strongest and your enemy weakest. By this it is possible you will be able to break through your adversary's game, in which some pieces must be exchanged. Now pause again, and survey both games attentively, and do not let your impetuosity hurry you on too far; at this critical juncture (especially if you still find your adversary very strong) rally your men, and put them in good order for a second or third attack, still keeping them close and connected, so as to be of use to each other. For want of this method, and a little coolness, an almost sure victory is often snatched out of a player's hands, and a total overthrow ensues.

3. At the last period of the game, observe where your pawns are strongest, best connected, and nearest to queen; likewise mind how your adversary's pawns are disposed, and compare these things together; and if you can get to queen before him, proceed without hesitation; if not, hurry on with your king to prevent him. I speak now as supposing all the higher pieces are gone; if not, they are to attend your pawns, and likewise to prevent your adversary from going to queen.—See *Hoyle, Jones, &c.*

To these rules and recommendations we add the following advice:—Conduct your game with coolness, take time to consider the chances for and against in moving, and do not give up the contest till all hope is gone of a retrieval. An anecdote has been told of two gentlemen playing at chess, one of whom found his game so hopeless that he declared himself beat; when an onlooker of more skill said he would undertake to win the game for him by three moves, without the possibility of being counteracted. The offer was accepted, and the game at once retrieved and won. As this is a particularly instructive incident, we shall state the positions of the pieces on the board in reference to the numbers of the squares on the diagram:—

The black rook was at 9, the black knight at 18, the black bishop at 20, the black king at 22, the black rook at 40, black pawns at 25, 26, 30, 35, and 36, and the black queen at 42. The white king was at 7, the white rooks at 61 and 63; the white knight at 47, and a white pawn at 38. The white has the move. The white knight at 47 gives check at 32; the black rook at 40 takes it. The white rook at 63 gives check at 23; the black king takes it. The white rook at 61 gives checkmate at 21. Thus the white, by a few dexterous moves, completely paralyses the adversary, and wins the game.

By writing an account of moves, it is possible for adversaries to carry on games at chess though at a great distance from each other. Thus chess clubs in London are known to carry on matches with clubs in Edinburgh or Paris, or even with a club in India. Games of this kind sometimes last for years.

The Morals of Chess, by Dr Franklin.

The game of chess is not merely an idle amusement; several very valuable qualities of the mind, useful in the course of human life, are to be acquired or strength-

ened by it, so as to become habits, ready on all occasions; for life is a kind of chess, in which we have often points to gain, and competitors or adversaries to contend with, and in which there is a vast variety of good and ill events that are in some degree the effects of prudence or the want of it.

By playing at chess, then, we may learn—

1.  *Foresight*, which looks a little into futurity, and considers the consequences that may attend an action; for it is continually occurring to the player, 'If I move this piece, what will be the advantage or disadvantage of my new situation? What use can my adversary make of it to annoy me? What other moves can I make to support it, and to defend myself from his attacks?'

2.  *Circumspection*, which surveys the whole chess-board, or scene of action; the relation of the several pieces, and their situations; the dangers they are respectively and repeatedly exposed to; the several possibilities of their aiding each other; the probabilities that the adversary may make this or that move, and attack this or the other piece; and what different means can be used to avoid his stroke, or turn its consequences against him.

3.  *Caution*, not to make our moves too hastily. This habit is best acquired by observing strictly the laws of the game, such as, 'If you touch a piece, you must move it somewhere;' 'if you set it down, you must let it stand.' And it is therefore best that these rules should be observed, as the game thereby becomes more the image of human life, and particularly of war; in which, if you have incautiously put yourself into a bad and dangerous position, you cannot obtain your enemy's leave to withdraw your troops, and place them more securely, but you must abide all the consequences of your rashness.

And lastly, we learn by chess the habit of *not being discouraged by present bad appearances in the state of our affairs*, the habit of *hoping for a favourable change*, and that of *persevering in the search of resources*. The game is so full of events, there is such a variety of turns in it, the fortune of it is so liable to sudden vicissitudes, and one so frequently, after long contemplation, discovers the means of extricating one's self from a supposed insurmountable difficulty, that we are encouraged to continue the contest to the last, in hopes of victory from our own skill, or at least of giving a stalemate, by the negligence of our adversary; and whoever considers—what in chess he often sees instances of—that success is apt to produce presumption and its consequent inattention, by which more is afterwards lost than was gained by the preceding advantage, while misfortunes produce more care and attention, by which the loss may be recovered, will learn not to be too much discouraged by any present success of his adversary, nor to despair of final good fortune upon every little check he receives in the pursuit of it.

That we may, therefore, be induced more frequently to choose this beneficial amusement in preference to others which are not attended with the same advantages, every circumstance which may increase the pleasure of it should be regarded; and every action or word that is unfair, disrespectful, or that in any way may give uneasiness, should be avoided, as contrary to the immediate intention of all parties, which is to pass the time agreeably.

Therefore, 1. If it is agreed to play according to the strict rules, then those rules are to be exactly observed by both parties, and should not be insisted on for one side while deviated from by the other; for this is not equitable.

2. If it is agreed not to observe the rules exactly, but one party demands indulgences, he should then be as willing to allow them to the other.

3. No false move should ever be made to extricate yourself out of a difficulty or to gain an advantage; for there can be no pleasure in playing with a person once detected in such unfair practices.

4. If your adversary is long in playing, you ought

## DRAUGHTS.

not to hurry him, or express any uneasiness at his delay. You should not sing, nor whistle, nor look at your watch, nor take up a book to read, nor make a tapping with your feet on the floor, or with your fingers upon the table, nor do anything that may distract his attention; for all these things displease, and they do not show your skill in playing, but your craftiness or your rudeness.

5. You ought not to endeavour to amuse and deceive your adversary, by pretending to have made bad moves, and saying that you have now lost the game, in order to make him secure and careless, and inattentive to your schemes. This is fraud and deceit, not skill in the game.

6. You must not, when you have gained a victory, use any triumphing or insulting expression, nor show too much of the pleasure you feel; but endeavour to console your adversary, and make him less dissatisfied with himself, by every kind and civil expression that may be used with truth, such as, 'You understand the game better than I, but you were a little inattentive;' or, 'You had the best of the game, but something happened to divert your thoughts, and that turned it in my favour.'

7. If you are a spectator while others play, observe the most perfect silence; for if you give advice you offend both parties—him against whom you give it, because it may cause the loss of his game; him in whose favour you give it, because, though it be good, and he follows it, he loses the pleasure he might have had if you had permitted him to think until that had occurred to himself. Even after a move or moves, you must not, by replacing the pieces, show how they might have been placed better; for that displeases, and may occasion disputes or doubts about their true situation. All talking to the players lessens or diverts their attention, and is therefore displeasing. Nor should you give the least hint to either party by any kind of noise or motion; if you do, you are unworthy to be a spectator. Should you have a mind to exercise or show your judgment, do it in playing your own game, when you have an opportunity, not in criticising, or meddling with, or counselling the play of others.

Lastly, if the game is not to be played rigorously according to the rules as afore-mentioned, then moderate your desire of victory over your adversary, and be pleased with one over yourself. Snatch not eagerly at every advantage offered by his unskillfulness or inattention; but point out to him kindly that by such a move he places or leaves a piece exposed and unsupported; that by another he will put his king in a dangerous situation, &c. By this generous civility (so opposite to the unfairness before forbidden) you may, indeed, happen to lose the game to your opponent, but you will win what is better, his esteem, his respect, and his affection, together with the silent approbation and good-will of impartial spectators.

When a vanquished player is guilty of an untruth to cover his disgrace, as, 'I have not played so long'—'his method of opening the game confused me'—'the men were of an unusual size,' &c. all such apologies must lower him in a wise person's eyes, both as a man and as a chess-player; and who will not suspect that he who endeavours to shelter himself under such untruths in trifling matters, is no very sturdy moralist in affairs of greater consequence, where his fame and honour are at stake! A man of proper pride would scorn to account for being beaten by one of these excuses, even were it true; because they all at the moment have the appearance of being untrue.

To this may be added a few 'cautions' of a different but equally important nature from a recent number of the 'Quarterly Review':—

'Chess not until the business of the day is fairly done, and you feel that you have earned your amusement.'

Chess not in mixed society, when it is likely that your antagonist and yourself will be missed from the circle by either hostess or company.

Chess not with persons much older than yourself, when you feel sure that you can beat them, but not sure that they will relish it.

Chess not with your wife, unless you can give her odds, and then take care rather to overmatch yourself.

Play not into the "small hours," lest the duties of the next day should suffer from scanty rest or late rising.

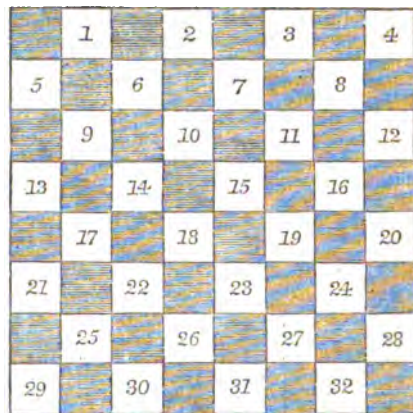

Do not commend your adversary's play when you have won, or abuse your own when you have lost. You are *assuming* in the first case, and *detracting* in the last.

Lastly, idolise not chess. To hear some people talk, one might think there was "nothing else remarkable beneath the visiting moon." Chess is not a standard for measuring the abilities of your acquaintance—nor an epitome of all the sciences—nor a panacea for all human ills—nor a subject for daily toil and nightly meditation. It is simply a recreation, and only to be used and regarded as such. The less selfish you are in its pursuit—the clearer head—the more patience—the better temper you bring to the practice of it, the better will you illustrate the merits of chess as the most intellectual of games, and establish your own character as a philosopher even in sport.'

## DRAUGHTS.

Draughts is a game with a chequered board and men, of much less antiquity than chess, and is perhaps to be considered a degenerate descendant of that noble sport. In France it is called *les dames*, from having been a favourite game with ladies; and in Scotland this signification is preserved in the term *dam-brod*, the name universally applied by the common people to the draught-board.

Draughts is played on a chess-board, or a board chequered precisely in the same manner, with thirty-two white, and thirty-two black squares. The board, however, is placed before the players differently; in chess there must be a white square in the right-hand corner, but in draughts the right-hand corner must be black (that is, supposing you to play on the white squares). The following is a representation of a draught-board, numbered for the sake of illustration and placed as it should be in playing:—

The game is played by two persons, who sit opposite to each other. Each party has a set of twelve men, the colour of the two being different for the sake of distinction. The men are generally round and flat pieces of wood; one set white, and another black; those of the neatest kind are turned out of boxwood and ebony.

The men may be placed either on the white or black squares, but the whole must be put on one colour only. It is customary in England to place all upon the white, and to have, as above, a black square on the right. In Scotland the black are played upon, when there is consequently a white square to the right. We go upon the supposition that the play is on the white squares, and have numbered them in the above figure accordingly.

The movements in draughts are very simple: a man can move only one square at a time, and diagonally,

never straight forward or sideways. If an enemy's man stand in the way, no move can take place, unless there be a vacant square beyond into which the piece can be lifted. In this case the man leaped over is taken; he is removed from the board.

The grand object of the game, then, is to clear the board of the enemy's men, or to hem them in so that they cannot move; and whichever party does so first gains the victory. As no piece can move more than one step diagonally at a time, there can be no taking till the two antagonists come to close quarters; and the pushing them cautiously into each other's neighbourhood is the principal art in the game.

When the men on either side have cleared their way by taking, or found an open path to the opposite side of the board, they become invested with a new power of movement: by reaching the first row of squares on the opposite side, the piece is entitled to be *crowned*, which is done by placing a man on the top of it. Thus crowned, the man may move backwards, but always diagonally, and one square at a time, as before. This power of moving and taking either forwards or backwards, renders it of consequence to get men crowned; and if two or three on each side gain this honour, the game becomes more interesting, and may speedily be determined.

Immediately after crowning, great art is shown in blocking up one or more of your adversary's men, by the aid of which to accomplish a series of decisive moves. For instance, supposing you have detained your adversary's piece at 4, while he has others situated on 25 and 26—and supposing you have pieces on 12 and 19, with a crowned man at 14, you may, by giving him your 12 and 19, exchange two pieces for three, which is commonly equivalent to winning the game. Again, supposing you have pieces on 13, 22, 30, and a crowned one on 26, and your adversary a piece on 5, with others scattered in the direction of 16, 8, 7, you may, by successively pushing before him your pieces on 13 and 22, gain a formidable exchange.

In beginning to play, much depends on having the first move; and the rule is, that in playing several games each party takes the first move alternately.

If a player touch one of his men, he must play it. If a player omit to take a man when it is in his power to do so, his adversary can *huff* or *blow* him—that is, either take the man, or insist upon his own man being taken. The practice is at once to lift the man which ought to have taken yours.

We present the following as an example of playing a game, in which white loses. The letters N, C, F, T, at the head of the columns, signify *Number, Colour, From, To*—

N	C	F	T	N	C	F	T
1	B	11	15	28	W	30	25
2	W	22	18	29	B	29	22
3	B	15	22	30	W	26	17
4	W	25	18	31	B	11	15
5	B	8	11	32	W	20	16
6	W	29	25	33	B	15	18
7	B	4	8	34	W	24	12
8	W	25	23	35	B	18	27
9	B	12	16	36	W	81	24
10	W	24	20	37	B	14	18
11	B	10	15	38	W	16	11
12	W	27	24	39	B	7	16
13	B	16	19	40	W	20	11
14	W	28	16	41	B	18	23
15	B	15	19	42	W	11	8
16	W	24	15	43	B	23	27
17	B	9	14	44	W	8	4
18	W	18	9	45	B	27	31
19	B	11	25	46	W	4	8
20	W	32	27	47	B	21	27
21	B	5	14	48	W	24	20
22	W	27	23	49	B	27	23
23	B	6	10	50	W	8	11
24	W	16	12	51	B	23	18
25	B	8	11	52	W	11	8
26	W	28	24	53	B	18	15
27	B	25	29	&c.	W	loses.	

It is not considered fair for any bystander to advise what motions should be taken, or for a player to wait longer than five minutes between each move. The draught player, therefore, must on all occasions act with much more promptitude and decision than in the case of chess. In short, draughts is a very ticklish game. A single false step may lead to irretrievable ruin; and it is only after long experience in figuring in the mind what would be the result of particular movements that proficiency is attained.

BACKGAMMON.

Backgammon is the modern name of a game of considerable antiquity in England, where it was formerly known by the appellation of 'the tables.' The words *back-gammon* have been ascribed to the Welsh tongue, in which they are said to signify *little battle*; but Strutt, with greater plausibility, traces the term to the Saxon '*bac* and *gamen*—that is, back-game; so denominated because the performance consists in the two players bringing their men back from their antagonist's tables into their own; or because the pieces are sometimes taken up and obliged to go back—that is, re-enter at the table they came from.' Whatever be the etymology of the term, the game has been long established in the country; and, as a freiside amusement of a decorous and exciting nature, is a favourite among clergymen, squires, farmers, and retired professional persons.

Backgammon is played with an apparatus consisting of a board or tables, men or pieces, dice, and dice-boxes. The introduction of dice into the game, and their constant use in determining moves, makes backgammon essentially a game of chance, and therefore brings two players of unequal talents nearer a level than other diversions in which skill is the sole or predominant element.

The backgammon board consists of two parts or tables, generally united by a hinge in the middle, by which they can be shut up as a box. Each table possesses twelve points, six at each end. These points are coloured white and black alternately; but this variation of colour has no reference to the game, and is only done to make the points more easily counted.

The game is played by two parties, and with 30 pieces or men; each party has 15 men, one set of 15 being black, and the other white. In beginning the game, the men are placed on certain points on the tables, as shown in the following figure.

The game is played with two dice and two dice-boxes. The dice are common to both; but each party uses his own dice-box, and the throws are alternate.

Each die is a perfect cube, marked on its sides with dots from 1 to 6. The 1 is called *ace*, the two *deuce*, the three *tre* or *trois*, the four *quatre*, the five *cinque*, and the six *six*. At every throw the two dice are employed; consequently a person may throw from two up to twelve—that is, two *aces* up to two *sizes*.

If a player throw *doublets*, or both dice of one number, double the number of dots is reckoned; thus by a throw of two aces the player does not count two, but four.

These numbers thrown or accidentally turned up by the dice, bear a reference to the points on the tables. In order to understand this connection between the dice and the men, the learner must observe how the men are placed on the points, and the rules by which their shifting from one to another is governed.

The tables are here spread out as if two partners were seated, and about to begin to play. The party owning the white men is seated at W, and the party owning the black men at B. We shall call one party White, and another Black. White counts round from the ace point of Black, and Black counts round from the ace point of White. These ace points are respectively seen to have two men upon them in opposite corners of the same table.

The grand object of the game is for each party to get

## BACKGAMMON—BILLIARDS.

all his men played round into the table containing the aces, removing them from point to point agreeable to the throws of the dice.

B  
The Backgammon Table.

In throwing, the number upon each die turned up may be reckoned by itself, or collectively, with the number on the other die. Thus if quatre be thrown by one die, and six by the other, a man can be advanced four points, and another six points; or one man can be advanced ten points, always providing that a point is open to suit this movement to it. No point can be moved to if covered by two men belonging to the adversary. If covered by only one man, which is called a *blot*, then that man can be hit, and be removed from the point, and placed on the bar between the tables, his place being taken by the man who has won it.

The removal of a man to the bars throws a player considerably behind in the game, because the man must remain out of the play till the dice turn up a number corresponding to one open point on the adversary's table. Being fortunate to get an open point by this means, the man must be entered and wrought round from thence, as in the case of others in the set to which he belongs. The frequent occurrence of this hitting of a blot gives an adversary a great advantage, and allows him to win the gammon.

There are two kinds of victory—winning the hit, and winning the gammon. The party who has played all his men round into his own table, and by fortunate throws of the dice has borne or played the men off the point first, wins the *hit*.

The gammon may be explained as follows:—When you have got all your men round to your own table, covering every point, and your adversary has a man out, then you are enabled to *bear* or lift your men away. If you can bear all away, so as to clear your table before the adversary gets his man placed by a throw on your table, you win the gammon. If the adversary has been able to bear one before you have borne all your men, it reduces the victory to a hit.

Two hits are reckoned equal to one gammon in playing matches. To win two games out of three is called winning the *rub*, as at whist.

### Hoyle's Directions for Bearing Men.

If a player has taken up two of the adversary's men, and happens to have two, three, or more points made in his own tables, he should spread his men, that he either may take a new point in his tables, or be ready to hit the man which the adversary may happen to enter. If he finds, upon the adversary's entering, that the game is upon a par, or that the advantage is on his own side, he should take the adversary's man up whenever he can, it being 25 to 11 that he is not hit; except when he is playing for a single hit only; then,

if playing the throw otherwise gives him a better chance for it, he ought to do it.

It being 5 to 1 against his being hit with double dice, he should never be deterred from taking up any one man of the adversary's.

If he has taken up one of the adversary's men, and should happen to have five points in his own tables, and forced to leave a blot out of his tables, he should endeavour to leave it upon doublets preferable to any other chance, because in that case the odds are 35 to 1 that he is not hit; whereas it is only 17 to 1 that he is hit upon any other chance.

When the adversary is very forward, a player should never move a man from his own quatre, trois, or deuce points, thinking to bear that man from the point where he put it, as nothing but high doublets can give him any chance for the hit. Instead of playing an ace or a deuce from any of those points, he should play them from his own size or highest points; so that throwing two fives or two fours, his size and cinque points being eased, would be a considerable advantage to him; whereas, had they been loaded, he must have been obliged to play otherwise.

It is the interest of the adversary to take up the player as soon as he enters. The blot should be left upon the adversary's lowest point—that is to say, upon his deuce point rather than upon his trois point; or upon his trois point rather than upon his quatre point; or upon his quatre point preferable to his cinque point—for a reason before-mentioned: all the men the adversary plays upon his trois or his deuce points are deemed lost, being greatly out of play; so that those men not having it in their power to make his cinque point, and his game being crowded in one place, and open in another, the adversary must be greatly annoyed by the player.

If the player has two of the adversary's men in his tables, he has a better chance for a hit than if he had more, provided his game is forwarder than that of his antagonist; for if he had three or more of the adversary's men in his tables, he would stand a worse chance to be hit.

When a player is running to save the gammon, if he should have two men upon his ace point, and several men abroad, although he should lose one point or two in putting his men into his tables, it is his interest to leave a man upon the adversary's ace point, because it will prevent his adversary from bearing his men to the greatest advantage, and at the same time the player will have a chance of the adversary's making a blot, which he may chance to hit. However, if a player finds, upon a throw, that he has a probability of saving his gammon, he should never wait for a blot, as the odds are greatly against his hitting it, but should embrace that opportunity.

## BILLIARDS.

This sport may be said to combine the principles of bowls, golf, and some other games in which objects are impelled from the hand. Whether the game was invented in France or England is not clearly ascertained; but as it is mentioned by Shakspeare, it is at least as old in this country as the sixteenth century. In the present day, it is pursued in every civilized country, but principally by the higher or leisurely classes of society. In France it is much more common than in England, where its character has suffered materially by the game having been made the subject of large gambling speculations. It is unfortunate that such should be the case, for no game is to be considered so purely scientific: it is *dynamics*, or certain laws of motion, put into practical operation; the hits or concussions of the balls exhibiting some of the finest examples of divergent forces.

Billiards is played with a table, certain kinds of rods, and balls. The table varies in size; that in most common use being from eight to twelve feet long, and from four and a-half to six feet in width. Whatever be its dimensions, it requires to be perfectly level and smooth.

It is ordinarily made of small pieces of wood joined together, so as to avoid warping, and these being brought to a dead level by planing, the surface is covered with fine green cloth. All round is a ledge two to three inches high, and stuffed as a cushion. The table is furnished with six pockets, one at each of the four corners, and one on each side at the middle. The mouths of these pockets or purses are level with the surface, so as to allow the balls to glide easily into them.

The balls are of ivory, about an inch and a-half in diameter. Two are white, and one is red. One of the white is distinguished by a spot. There are usually two players; he who owns the plain ball is called *Plain*, and he who owns the spotted ball is termed *Spot*. The red ball belongs to neither, but is aimed at by both.

The rods or bills used by the players are of two kinds, and different lengths, to suit different players. The ordinary kind of rod is called a *cue*. It is long and smooth, with one end thick and heavy, and the other more slender. The other kind of rod is termed a *mace*; it has a club-like extremity, and is much less frequently used. Almost all players employ cues of the length which suits them.

In playing, the left hand is rested with the palm undermost on the table. The palm is hollowed, and the thumb, close to the forefinger, is raised up to form a bridge or rest for the cue. The hand is to be at the distance of about six inches from the ball. The cue is lightly held in the right hand, the thick end uppermost, the blow being struck with the small extremity. Thus held, in a free but firm manner, and resting on the channel between the forefinger and thumb, the cue is given a sharp run forward, so as to hit the ball in the required direction, and with that exact degree of force which will make it perform the desired feat. To prevent slipping, the point of the cue is generally chalked.

The table is laid out as follows for play:—At the distance of about a foot from one end, in the centre of the table, is a small dot or mark in the cloth, on which the red ball is placed. At a similar distance from the other, which we shall call the upper end of the table, a line is made across by a chalked string; and in the middle of this line there is a mark on which the white ball of a player is to be struck from.

The leading principle in the sport is for a player to impel his white ball against the red ball, and drive them into a pocket or pockets; or to perform a still greater feat of striking the red ball, the adversary's ball, and his own ball, into pockets. It must be understood that nothing is gained by a player striking his own ball direct into a pocket; anybody could do that, and there would be no science in it. The merit consists in impelling balls against each other, at such an exact angle that one or both may be pocketed; and the skill displayed in this is often very surprising.

In setting out in a game, the first stroke or lead is determined by lot. This is called *stringing* for the lead. Each player hits his ball from the *string* or line, and he who causes it to rebound from the bottom cushion and come back nearest to the upper cushion, has the lead and the choice of the balls.

The first player begins by striking his ball from the string against the red ball, as already mentioned; and if he pockets the balls, he scores a certain number, and begins again. So long as he pockets, the adversary does not get a stroke. If the player miss, the adversary takes his turn. Both now play alternately, hitting the balls where they chance to lie; but when one pockets, he starts afresh by striking from the string.

A person in attendance *scores* or keeps reckoning of the play. He does this by means of two indices moving round a figured circle, and when one is gained, he turns the index accordingly. Technically, he is told to score one for Plain or one for Spot.

Hitherto we have spoken of billiards as one game, but it is necessary to explain that at least twelve different games may be played. We shall notice the two following as those in common use:—

Winning and Losing Game.

This is played by two persons, and twenty-one points are the game. The following are Hoyle's regulations for playing it:—

1. The game commences, as usual, with stringing for the lead, as well as the choice of balls. The ball in stringing to be placed within the circle, and the striker must stand within the corners of the table. The ball which rebounds from the bottom cushion, and comes nearest to the cushion within the bank, takes the lead, and has the choice of balls.
2. If the adversary to the first person who has strung for the lead should cause his ball to touch the other, he loses the lead thereby.
3. When a player holds the ball in stringing or leading, his lead is forfeited.
4. If a ball is followed by either mace or cue beyond the middle hole, it is no lead; the adversary of course may force him to renew his lead.
5. After every losing hazard, the ball is to be replaced within the nails or spots, and within the ring.
6. The place for the red ball is on the lowest of the two spots at the bottom of the table.
7. The red ball being holed, or forced over the table, is placed immediately on the lowest of the two spots; the present player is, besides, compelled to see it thus replaced, else he cannot score any points while it is off the spot; the stroke of course is foul.
8. When the player misses his adversary's ball, he loses one; but should he at the same time pocket his own ball, he then loses three besides the lead.
9. The adversary's ball, and the red ball also, being struck by a player.
10. When the striker, after making a hazard or carambole, accidentally forces his own or either of the other balls over the table, he loses all the advantages he has gained besides the lead.
11. When a ball is accidentally forced over the table, the striker loses the lead.
12. To strike your adversary's ball and the red one too, you score two; this is called a *carom* or *carambole*.
13. To hole the adversary's or the white ball, you score two. To hole the red ball you score three.
14. When the striker holes his own ball off his adversary's, he scores two points; but if he holes his ball off the red, he scores three. But if he holes both the red and his adversary's balls, he scores five. If the player holes the red and his own ball, he scores six.
15. If the striker holes his own and his antagonist's ball, he scores four.
16. When the striker plays at the white ball, and should hole the red after that, and his own ball besides, he scores five—two for holing the white, and three for the red.
17. When the striker, playing on the red ball first, should pocket his own as well as his adversary's ball, he scores five points; three for holing off the red, and two for holing his own.
18. If the player holes his adversary's ball, his own, and the red, he scores seven points; namely, two for holing off the white, two for the adversary's holing, and three for holing the red ball.
19. Should the striker hole his own ball off the red, and hole the red and his adversary's too at the same stroke, he scores eight points thus: three for holing himself off the red, three for the red itself, and two for holing his adversary.
- \*.\* All the above games, commencing with the thirteenth, are scored without the caramboles; the following are those in which the caramboles occur:—
20. When a carambole is made, and the adversary's ball is pocketed, four are scored; namely, two for the carambole, and two for the white.
21. If the striker pockets the red ball after making a carambole, he scores five; two for the carambole, and three for the red.
22. If the striker should hole both his adversary's and the red ball, after having caramboled, he scores seven; two for the carambole, two for the white, and three for the red ball.
23. When a carambole is made by striking the white ball first, and the striker's ball should be holed by the same stroke, four points are gained.
24. When the striker makes a carambole by striking the red ball first, and should hole his own ball at the same time, he gains five points; three for the red losing hazard, and two for the carambole.
25. If in playing at the white ball first, you should make a carambole, and hole your own and adversary's ball at the same time, you score six points; namely, two for each white hazard, and two for the carambole.
26. The striker wins seven points when he caramboles off the red ball, and holes his own and his adversary's ball; namely, two for the carom, two for the white, and three for the red hazard.
27. When the player caramboles by playing first at the white, and should also hole his own and the red, he scores seven points; namely, two for the carom, two for the white losing hazard, and three for the red winning hazard.
28. When the player caramboles by hitting the red ball first, and also holes his own and the red, he scores eight; namely, two for the carom, three for the red winning hazard, and three for the red losing hazard.

## BILLIARDS.

29. Should a player carambole on the white ball first, and then hold his own ball and his opponent's, and the red ball besides, he then scores nine; thus two for the carom, two for each white, and three for the red hazard.

30. If a carambole is done by striking the red ball first, and at the same stroke the player holds his own ball, the red ball, and his adversary's too, he gains ten points, upon the principle of the preceding rule.

31. When your adversary's ball is off the table, and the other two balls are upon the line or inside of the stringing nails at the leading end of the table, it is named being within the baulk. The player, therefore, striking from the ring, must make his ball rebound from the opposite cushion, so as to hit one of the balls within the baulk; if he misses, he loses a point.

32. Now and then it occurs that after the red ball has been forced over the table or holed, one of the white balls has so taken up the place of the red ball, that it cannot be replaced in its proper situation without touching it. In such, the marker holds the red ball in his hand, while the player strikes at his opponent's ball.

33. And directly after the stroke, replaces it on the proper spot, in order that it may not prevent a carambole from being made.

34. When the striker plays a wrong ball, it is reckoned a foul stroke.

35. When the player is about to strike at or play with the wrong ball, none in the room can with propriety discover it to him, his partner excepted, if they are playing a double match.

36. When the player, after making a carom or a hazard, should, either with his hand, cue, or mace, move either of the balls remaining on the table, the stroke is foul.

37. If the striker should play with the wrong ball, and this erroneous play should not be discovered by his opponent, the marker is obliged to score, and he is a winner of all the points he has gained by the stroke.

38. None can move or touch a ball without permission of the adversary.

39. Sometimes a ball happens to be changed in the course of the game, and it cannot be ascertained by which player; in that case the balls must be used as they then are, and the game so played out.

40. It is a foul stroke when the striker, in the act of playing, should happen to touch his ball twice.

41. Sometimes the player accidentally touches or moves his ball, without intending to strike. In that case he loses no point, but his ball may be replaced as it originally stood.

42. When a striker's adversary or spectator impedes the player's stroke by accident or design, he has a right to renew his stroke.

43. Should a player, in the act of striking, hit his ball, and cause his cue or his mace to go over it or past it, he forfeits a point.

44. No striker can play upon a running ball; such stroke is foul.

45. An accidental stroke is to be considered good if attended with the proper effect, though, by missing the cue, &c. it is not intended as such.

46. Should a striker, in attempting to play, not hit his ball at all, it is no stroke, and he is to try again.

47. Should the striker or his adversary, in the act of playing, move by accident or design the opponent's white or red ball from the place it occupied on the table, the stroke is foul.

48. When the striker's ball and either of the other balls are so close as to touch each other, and in striking at the former, either of the latter is moved from its place, the stroke is foul.

49. Whoever stops a running ball in any way loses the lead, if the opponent does not like the situation of the ball he has to play at next time.

50. It may happen that a striker, after having made a carambole or a hazard, interrupts, by accident, the course of his own ball; in this case he scores nothing, as the stroke is foul.

51. Should a player impede the course of his own ball, after having made a miss, and it is running towards the hole, and it is so thought also by the marker, he loses three points.

52. To stop, retain, or impede the adversary in the act of striking, is deemed foul.

53. Should a player in any way interrupt, stop, or drive his adversary's ball out of its course when running towards a pocket, he forfeits three points.

54. Even blowing upon a ball whilst running makes a stroke foul; and should the striker's ball be making its way towards a hole, and he blow upon it, he loses two points by such act.

55. If a mace or cue is thrown upon the table during a stroke, it is baulking the striker, and the stroke is considered foul.

56. No play is deemed correct when both feet are off the ground.

57. If the table is struck when a ball is running, the stroke is deemed foul.

58. A player leaving a game unfinished loses that game.

59. Some tables are so uneven that they give way toward the sockets. In case a ball should go to the brink of a hole, and after here resting for a few seconds, should drop into it, such tells or nothing; and the ball must be again placed on the brink before the adversary strikes again; and should it fall into the hole again the moment the striker has played his ball, so as to frustrate the intended success of his stroke, the striker's and his opponent's balls must be placed as they were originally, and the strokes played over again.

60. When a player's mace or cue should touch both balls in the act of striking, the stroke is foul; and if noticed by his opponent, nothing is gained on the points made by the stroke; and the opponent may, if he pleases, part the balls also.

61. Those who agree to play with the cue must do so during the whole of the match; but if no conditions of this sort have been made, the player may change as he pleases. No player can, without permission of the adversary, break his agreement.

62. If a foul stroke is made, the adversary may either part the balls and play from the ring, or, if the balls should be favourably placed for himself, permit the striker to score the points he had gained, which the marker is bound to do in all cases where the balls are not broken.

63. All agreements are specially binding. For instance, those who agree to play with the cue point and point, cannot use the butt without permission; but they may use the long cue; and the same with those who agree to play with the butt only.

64. A striker wins, and the marker is obliged to score all the points he gains, by unfair strokes, if the adversary neglects to detect them.

65. He who offers to part the balls, and the adversary agreeing to the same, the offerer loses the lead by such proposal.

66. None (unless they belong to a four match) have a right to comment on a stroke, whether fair or foul, until asked; and in the above case, none but the player and his partner can ask it.

67. When disputes arise between the players, the marker alone decides, and there is no appeal from his decision. But it may occur he might have been inattentive to the stroke; in that case he is to collect the sense of the disinterested part of the company; namely, those who have no bets on the stroke, and their decision is to be final.

### The White Game.

Two players are engaged as above, and the striking is alternate. The general principle is, that you win if you pocket the red ball or your adversary's ball, but invariably lose if by any means you hole your own ball. The number of points in the game is twelve. The following are Hoyle's regulations:—

1. In beginning, string for the lead, and the choice of balls, if you please.

2. When a person strings for the lead, he must stand within the limits of the corner of the table, and also must not place his ball beyond the stringing nails or spots; and he who brings his ball nearest the cushion wins the lead.

3. If after the first person has strung for the lead, and his adversary who follows him should make his ball touch the other, he loses the lead.

4. Should the player hole his own ball, either in stringing or leading, he loses the lead.

5. Should the leader follow his ball with either mace or cue past the middle hole, it is no lead; and if his adversary chooses, he may make him lead again.

6. The striker who plays at the lead must stand with both his feet within the limits of the corner of the table, and must not place his ball beyond the stringing nails or spots; and his adversary (only) is bound to see that he stands and plays fair, also the striker wins all the points he made by that stroke.

7. When a hazard has been lost in either of the corner holes, the leader is obliged (if his adversary requires it) to lead from the end of the table where the hazard was lost; but if the hazard was lost in either of the middle holes, it is at the leader's option to lead from either end of the table he pleases.

8. If the striker misses his adversary's ball, he loses one point; and if, by the said stroke, his ball should go into a hole, over the table, or on a cushion, he loses three points; namely, one for missing the ball, and two for holing it, &c.; and he loses the lead.

9. If the striker holes his adversary's ball, or forces it over the table, or on a cushion, he loses two points.

10. If the striker holes his own ball, or forces it over the table, or on a cushion, he loses two points.

11. If the striker holes both balls, or forces them over the table, or on a cushion, he loses two points.

12. No one has a right to take up his ball without permission from his adversary.

13. If the striker, by accident, should touch or move his own ball, not intending to make a stroke, it is deemed as an accident; and his adversary, if he requires it, may put the ball back in the place where it stood.

14. If the striker forces his adversary's ball over the table, and his adversary should chance to stop it, so as to make it come on the table again, the striker nevertheless wins two points.

15. When the striker forces his own ball over the table, and his adversary should chance to stop it, so as to make it come on the table again, the striker loses nothing by the stroke, and he hath the lead; because his adversary ought not to stand in the way, or near the table.

16. If the striker misses the ball, and forces it over the table, and it should be stopped by his adversary, as before mentioned, he loses one point, and has the lead, if he chooses.

17. If the striker, in playing from a cushion or otherwise, by touching the ball, makes his mace or cue go over or past it, he loses one point; and if his adversary requires it, he may put the ball back, and may make him pass the ball.

18. If the striker, in attempting to make a stroke, doth not touch his ball, it is no stroke; and he must try again to make a stroke.

19. If, when the balls are near each other, and the striker by

## CHAMBERS'S INFORMATION FOR THE PEOPLE.

accident should make his ball touch the other ball, it is nevertheless a stroke, though not intended as such.

50. If the striker who plays the stroke should make his adversary's ball go so near the brink of a hole as to be judged to stand still, and afterwards should fall into it, the striker wins nothing; and the ball must be put on the same brink where it stood, for his adversary to play from the next stroke.

*N.B.*—There is no occasion for challenging the ball if it stops, as some imagine.

51. If the striker's ball should stand on the brink or edge of a hole, and if, in playing it off, he should make the ball go in, he loses three points.

52. If a ball should stand on the brink or on the edge of a hole, and it should fall into the hole before or when the striker has delivered his ball from his mace or cue, so as to have no chance for his stroke, in that case the striker and his adversary's balls must be placed in the same position, or as near as possible thereto, and the striker must play again.

53. The striker is obliged to pass his adversary's ball, more especially if he misses the ball on purpose; and his adversary may, if he chooses, oblige him to place the ball where it stood, and play until he has passed.

54. If the striker plays both balls from his mace or cue, so that they touch at the same time, it is deemed a foul stroke; and if it is discovered by his adversary, and a dispute should arise thereon, he has an undoubted right to appeal to the disinterested company then present; and if determined by the majority of the disinterested company, and the marker, if needful, to be a foul stroke, then it is at his adversary's option (if not holed) either to play at the ball or take the lead. But if, by the above-mentioned stroke, his adversary doth not discover it to be a foul stroke, then the striker may reckon all the points he made by the said stroke, and the marker is obliged to mark them.

55. No person hath a right to discover to the player whether the stroke is fair or foul, until it is asked.

56. If by a foul stroke the striker should hole his adversary's ball, he loses the lead.

57. If by a foul stroke the striker holes his own or both balls, or forces his own or both balls over the table, or on a cushion, he loses two points.

58. If the striker plays on a ball when it is running or moving, it is deemed as a foul stroke.

59. If the striker plays with both feet off the ground, without the permission of his adversary, it is deemed a foul stroke.

60. If the striker plays with a wrong ball he loses the lead, if his adversary requires it.

61. If the ball should be changed in a hazard or on a game, and it is not known by which party, the hazard must be played out by each party with their different balls, and then changed.

62. If the striker plays with his adversary's ball, and holes or forces the ball he played at over the table, &c. it is deemed a foul stroke.

63. If the striker plays with his adversary's ball, and holes or forces the ball he played with over the table, &c. he loses two points; and if he missed the ball, three points.

64. If the striker plays with his adversary's ball, and misses it, he loses one point; and if his adversary discovers that he hath played with the wrong ball, he may part the balls, and take the lead if he pleases.

65. In all the before-mentioned cases of the striker's playing with the wrong ball (if discovered), his adversary must play with the ball the striker played at throughout the hazard, or part the balls and take the lead.

66. Whoever stops a ball when running with hand, stick, or otherwise, loses the lead, if his adversary does not like the ball he has to play at the next stroke.

67. Whoever retains his adversary's stick when playing, it is deemed foul.

68. If the striker stops or puts his own ball out of its course when running towards either of the holes, and if adjudged by the marker and the disinterested company then present to be going into a pocket, if he missed the ball he loses one point, and, if going into a hole by the same stroke, three points.

69. If the striker stops or puts his adversary's ball out of the course when running towards or into a hole, or puts his adversary's ball into a hole, it is deemed a foul stroke.

*N.B.*—If the adversary doth the same as in the foregoing rules, he is subjected to the same penalties as the striker.

70. He who shakes the table when the ball is running makes it a foul stroke.

71. He who throws his stick upon the table, so as apparently to be of any detriment to his adversary, makes it a foul stroke.

72. He who blows on the ball when running makes it foul. And if his own ball was running towards or near the hole, he loses two points.

73. He who leaves the game before it is finished, and will not play it out, loses the game.

74. Any person may change his mace or cue in playing, unless otherwise previously agreed on.

75. When two persons are at play, and no particular terms of agreement have been made, neither party has a right to object to either mace or cue being played within the said game.

76. When the parties agree to play mace against cue, the mace player hath no right to use a cue, nor has the cue player any right to use a mace during the game or match, without permission from his adversary.

77. When a person agrees to play with the cue, he must play

every ball within his reach with the point thereof; and if he agrees to play with the butt of the cue, he has no right to play with the point thereof, without permission from his adversary.

78. When the parties agree to play point and point of the cue, neither of them has a right to use a butt during the game or match without permission, &c., but they have a right to play with the point of a long cue over a mace, &c.

79. When the parties agree to play all point with the same cue, they have no right to use any other during the game or match.

80. Whoever proposes to part the balls, and his adversary agrees to it, the proposer thereof loses the lead.

81. Two missings do not make a hazard, unless it is previously agreed on to the contrary.

82. In all cases, the betters are to abide by the players on the determination of the hazard, or on the game; and the betters have a right to demand their money when their game is over, to prevent disputes.

83. Every person ought to be very attentive, and listen for the stroke, before he opens the door of a billiard-room.

84. The striker has a right to command his adversary not to stand facing him, nor near him, so as to annoy or molest him in the stroke.

85. Each party is to attend to his own game, and not to ask if his adversary's ball be close?—if he touches his ball?—if he can go round the ball?—nor any question of the like tendency; nor is any one to be set right, if going to play with the wrong ball.

86. When four persons play, the game is fifteen in number, and each party has a right to consult with and direct his partner in anything respecting the game, &c.; and the party who makes two missings before a hazard is made, is out, and it is his partner's turn to play; but if, after the two missings have been made by the party, his adversary should hole a ball, so as to make a hazard, the stroke following the said two missings have been made, yet the party who did not make the two missings is to play, as he cannot be supposed to be out who has not made a stroke.

### BAGATELLE.

The large and inconvenient size of billiard-tables has led to the introduction of bagatelle-tables—*bagatelle* being the French word for anything trifling. A bagatelle-table is usually about five feet long and eighteen inches broad; it is lined with cloth, and a game is performed on it with balls and a cue or mace. The balls are small ivory spheres, and the sport very much consists in striking one or more into holes at one end of the board. To perform this and other feats, some skill and experience are required, and the sport is far from unamusing in a cheerful parlour circle. Of late years, bagatelle-tables have become very common in the houses of the middle classes of society; they possess the recommendation of being purchasable at a small expense.

### GAMES WITH CARDS.

Playing-cards are small oblong pieces of pasteboard, on which divers figures are impressed in two principal colours—red and black. Fifty-two cards form a *pack*, or complete set for playing any game. The pack consists of four *suites* or kinds of cards, thirteen in each, distinguishable by their respective marks. The suites are *hearts*, *diamonds*, *clubs*, and *spades*. Hearts and diamonds are red; clubs and spades are black. The thirteen in each suite consist of ten cards, distinguishable by spots, from one to ten; and three cards, ordinarily called *court cards*, from being impressed with certain figures having a semblance of court costume—one of these is the *king*, another the *queen*, and a third the *knave* or *jack*.

Of the origin of playing-cards, and the signification of their respective markings, there has been no small controversy among antiquaries. The general opinion has been that cards were invented about the year 1392, for the purpose of amusing Charles VI. of France, at the time he was afflicted with a mental depression or derangement. But it has been ascertained that, in 1387, John I., king of Castile, issued an edict forbidding the playing of cards in his dominions; and from this, as well as from some of the names given to the cards, it is extremely probable that playing-cards were known in Europe as early as about the middle of the fourteenth century. At first, the outlines of the figures on the cards were made by stamps, and afterwards filled up by the hand; but soon after the invention of engraving on blocks, the devices were produced by wood,

## GAMES WITH CARDS.

and sufficiently finished, so that the impressions did not require any assistance from the pencil.

The names—hearts, diamonds, spades, and clubs—which the English give to the cards, appear to be in a great measure a corruption of the original Spanish and French appellations, or a misapplication of terms to the original symbols. We find the following account given of the design and names of the cards in the work of an anonymous writer:—

‘The inventor proposed, by the figures of the four suites, or colours, as the French call them, to represent the four states or classes of men in the kingdom.

By the *Cæsars* (hearts) are meant the *gens de chœur*, choir men, or ecclesiastics; and therefore the Spaniards, who certainly received the use of cards from the French, have *copas*, or chalices, instead of hearts.

The nobility or prime military part of the kingdom are represented by the ends or points of lances or pikes, and our ignorance of the meaning or resemblance of the figure induced us to call them spades. The Spaniards have *espades* (swords) in lieu of pikes, which is of similar import.

By diamonds are designed the order of citizens, merchants, and tradesmen, *carreux* (square stone tiles or the like). The Spaniards have a coin, *dineros*, which answers to it; and the Dutch call the French word *carreux*, *stieneen*, stones and diamonds, from the form.

*Treffe*, the trefoil leaf, or clover grass (corruptly called clubs), alludes to the husbandmen and peasants. How this suite came to be called clubs is not explained, unless, borrowing the game from the Spaniards, who have *boscos* (staves or clubs) instead of the trefoil, we gave the Spanish signification to the French figure.

The history of the four kings, which the French in drollery sometimes call the cards, is *David*, *Alexander*, *Cæsar*, and *Charles* (which names were then, and still are, on the French cards). These respectable names represent the four celebrated monarchies of the Jews, Greeks, Romans, and Franks, under Charlemagne.

By the queens are intended *Argine*, *Eaith*, *Judith*, and *Pallas* (names retained in the French cards), typical of birth, piety, fortitude, and wisdom, the qualifications residing in each person. *Argine* is an anagram for *regina* (queen by descent).

By the knaves were designed the servants to knights (for knave originally meant only servant; and in an old translation of the Bible, St Paul is called the knave of Christ); but French pages and valets, now indiscriminately used by various orders of persons, were formerly only allowed to persons of quality; esquires (*escuiers*), shield or armour-bearers.

Others fancy that the knights themselves were designed by those cards, because *Hogier* and *Lahire*, two names on the French cards, were famous knights at the time cards were supposed to be invented.\*

With the entire pack of fifty-two cards, or with only a portion of it, there have been innumerable games, and there are so still; to notice the whole of these, however, would occupy too much of our space, and we propose to confine our explanations to what are considered respectable and harmlessly-amusing games.

### WHIST.

All games at cards, in our opinion, are insignificant in comparison with *whist*, which is believed to take its name from an old exclamation to keep silence; it must at least be conducted noiselessly, and with extreme attention. The whole structure of the game is ingenious, and a result of just calculation. Its rules have all been carefully studied, and there seems to be a sufficient reason why each has been instituted. The game is a happy blending of skill and chance; skill being the most important element, and chance only accessory, in order to impart a due relish or piquancy to the sport, and deprive highly-skilled players of being always certain of the victory.

Whist is played by four persons, two forming a party or side. The four sit at a square table, one on each side, partners being opposite to each other. The table

should be covered with cloth, to permit an easy lifting of the cards. Before commencing the game, a pack of cards is laid on the table, the faces undermost. The parties then *cut* for partners; that is, they leave it to chance to determine who shall be partners. This is done by each person lifting or *cutting* a portion of the cards from the heap or pack, and the two who have the highest cards play together.

The *value* of the cards is as follows:—As already stated, there are four suites, each suite consisting of thirteen cards, ten being common, and three being court cards. The card in each suite which has but one mark is called the *ace*; and this ace is the highest in value in all cases except in cutting for partners, when it is the lowest. The next highest is the king, the next the queen, the next the knave; then the ten, nine, eight, and so on down to the two, or *deuce*, which is the lowest. In playing whist, one suite is of higher value than any of the other three; but which suite shall possess this temporary distinction depends on chance in dealing out the cards; the last card dealt out is turned up, and the suite to which it belongs is called *trumps*;<sup>\*</sup> trumps, then, is the suite of the highest value. In the course of a game, the trump suite may of course vary at every deal.

The *cutting* of the pack, as above-mentioned, determines who are to be partners, and at the same time determines who is to *deal*. The rule is, that he who had the lowest card in cutting is the dealer. This person *shuffles* the cards; that is, mixes them in any way he thinks proper, always keeping the backs towards him. Having done this, his adversary is entitled to shuffle the cards also; indeed each person has a right to shuffle them, but this is seldom done. Being duly shuffled, the pack is laid on the table (always backs uppermost) before the *youngest hand*, or the person sitting to the right hand of the dealer; and he cuts it, by lifting off a portion and laying it down. The dealer now puts the lower portion on the top of the portion laid off, and is prepared for dealing.

*Dealing* must be neatly performed; the dealer holding the pack in his left hand, lifts off the top cards with his right, and distributes them, one to each, all round. He begins with the person on his left, who is called the *elder hand*, then the person opposite, then the youngest hand, and then himself. He thus goes thirteen rounds, the last card which he holds in his hand falling to his own share. This last card he turns up, and it determines the suite to be trumps. The dealer, therefore, has at least always one trump in his hand, but this advantage is supposed to be neutralised by the adversaries having a knowledge of one of his cards. The trump card lies on the table exposed till the first trick is played. Any exposure of a card in dealing, by real or pretended accident, is strictly provided against. The following are Hoyle's

### Rules for Dealing.

If a card is turned up in dealing, the adverse party may call a new deal if they think proper; but if either of them has been the cause of turning up such card, then the dealer has the option.

If a card is faced in the deal, there must be a fresh deal, unless it happens to be the last card.

It is the duty of every person who plays to see that he has thirteen cards. If any one happens to have only twelve, and does not find it out till several tricks are played, and that the rest have their right number, the deal stands good, and the person who played with the twelve cards is to be punished for each revoke, provided he has made any. But if any of the rest of the players should happen to have fourteen cards, in that case the deal is lost.

The dealer should leave his trump card upon the table till it is his turn to play; and after he has mixed it with his other cards, no one has a right to demand what card was turned up, but may ask what suite is trumps: in consequence of this law, the dealer cannot name a wrong card, which otherwise he might have done.

None of the players may take up or look at their cards while they are dealing out: when this is the case, the dealer, if he should happen to miss deal, has a right to deal again, unless it arises from his partner's fault; and if a card is turned up in

\* The term *trump* is believed to be a corruption of *triumph*, meaning the triumphant card.

## CHAMBERS'S INFORMATION FOR THE PEOPLE.

dealing, no new deal can be called, unless the partner was the cause of it.

If any person deals, and instead of turning up the trump, he puts the trump card upon the rest of his cards, with the face downwards, he loses his deal.

### Playing the Game.

The cards being all dealt, each takes up his hand, which he must scrupulously prevent any of his antagonists or his partner from seeing. The cards should be ranged like a fan in the left hand, so that its holder can see all his cards at a glance. It is advisable, for the sake of order and convenience, to arrange the cards in the hand, all of a suite together. Each having his cards sorted, the game commences by the elder hand, or person on the left of the dealer, laying down a card. The person on his left follows, and so on to the dealer, who lays down last.

The principle of playing is as follows:—Whatever suite the first card is of, that suite must, if possible, be followed by each party round; but if one party has not a card of that suite, he can lay down one of any other suite. Should he do so, and afterwards lay down a card of the suite which he appeared to be deficient of, he has committed a *revoke*, and a penalty is exacted in loss of three tricks. It is necessary, for the sake of fair play, to be very rigorous in punishing a revoke.

The four cards laid down in a round is called a *trick*. The trick is won in various ways. The card of the highest value wins. For example, if the first player lays down a deuce of spades, the second a three of spades, the third a four of spades, and the fourth a five of spades, this last person wins; his party gains a trick. But should one of the players not have a spade in his hand, and lays down a deuce of the suite which happens to be trumps, that card wins. No matter how high in value the cards laid down are, the trick is always won by a trump card, though it were only a deuce. If several trump cards be laid down, or all be trumps, then the highest trump card wins. The ace of trumps is the highest card.

When the trick is played, it is lifted by the person who wins, and placed beside him in a heap on the table, back uppermost; and he continues to take up all other tricks his party wins. Thus one on each side collects and reckons the tricks.

Whoever wins the trick becomes elder hand, and plays first in next round; and so on each winner plays first till all the cards are played out.

A pack produces thirteen tricks, but none is counted till after six. For instance, if one party wins four tricks, they do not count; and the other party which has nine tricks counts three. Should one party gain all the tricks, it counts seven.

The ace, king, queen, and knave of trumps are called *honours*. These have a peculiar value in reckoning towards the game. Should each person hold one honour, honours do not count; but should two partners hold three honours between them, they score two points; when they hold four, they score four points.

The game consists of ten *points*, and these may be gained by tricks and by honours. Should a party make six tricks and hold four honours, it has won the game at one deal. It will therefore be perceived that honours, the possession of which is a matter of mere chance, exert a powerful influence in gaining the victory over an adversary.

Only at one time in the game do honours not count; this is when the party is at nine; the odd point to make up to ten being only gained by tricks. When a party is at eight, and the first trick has been played, one of that party, who holds two honours, may ask his partner if he has one honour; and if he says he has, the three honours are at once shown, which concludes the game. There are rules for calling honours, which we subjoin.

In the course of playing the game, no one must drop the slightest hint how he wishes his partner to play, or make any other observation calculated to mislead or direct. Neither may any one, before his partner has played, inform him that he has or has not won the

trick; even the attempt to take up a trick, though won before the last partner has played, is deemed very improper.

All parties must play by their own perceptions of what would be most judicious. There is only one exception to the rule of keeping silence, which is in the case of a revoke. If a person happens not to follow suite, or trump a suite, the partner is at liberty to inquire of him whether he is sure he has none of that suite in his hand. This indulgence must have arisen from the severe penalties annexed to revoking, which affects the partners equally, and is now universally admitted.

The great knack in playing whist is to *remember what is out*, and hence, by the play of both partner and adversaries, to have a shrewd guess of what each holds in his hand. A primary rule is to follow a partner's lead, as it is presumed that no one, in playing first, is without a good reason for tabling a particular suite.

The term *finessing* signifies the attempt to gain an advantage; thus if you have the best and third best card of the suite led, you put on the third best, and run the risk of your adversary having the second best; if he has not, which is two to one against him, you are then certain of gaining a trick.

A *loose card* is a card of no value, and consequently the most proper to throw away; it would be folly to lay a good card down, when it must clearly be taken by a better card already tabled.

A *sequence* is a succession of cards in the same suite; as ace, king, queen, knave.

*Tenace* is possessing the first and third best cards, and being last player; you consequently conquer the adversary when that suite is played.

*Scoring* is the method of reckoning the points in a game. The reckoning is made by four counters, or pieces of money; and the way in which these pieces are disposed shows the score. The following is the ordinary method of scoring:—

1	2	3	4	5	6	7	8	9
				0	0	00	000	0
0	00	000	0000	00	000	0	0	0

### Rules for Playing.

If a person plays out of his proper turn, or shows a card, it is in the option of either of his adversaries to call that card; that is, cause him to lay it down at any time in that deal, provided it does not make him revoke; or either of the adversaries may require of the person who ought to have led, the suite the said adversary may choose.

If a person supposes he has won the trick, and leads again before his partner has played, the adversary may oblige his partner to win it if he can.

If a person leads, and his partner plays before his turn, the adversary's partner may do the same.

If the ace or any other card of a suite is led, and the last player should happen to play out of his turn, whether his partner has any of the suite led or not, he is neither entitled to trump it nor to win the trick, provided you do not make him revoke.

If a revoke happens to be made, the adversaries may add three to their score, or take three tricks from the revoking party, or take down three from their score; and if up, notwithstanding the penalty, they must remain at nine: the revoke takes place of any other score of the game.

If any person revokes, and discovers it before the cards are turned, the adversary may call the highest or lowest of the suite led, or call the card then played, at any time when it does not cause a revoke.

No revoke can be claimed till the trick is turned and quitted, or the party who revoked, or his partner, have played again.

If a revoke is claimed by any person, the adverse party are not to mix their cards, upon forfeiture of the revoke.

No person can claim a revoke after the cards are cut for a new deal.

If any person calls, except at the point of eight, the adversaries may call a new deal, if they think proper.

After the trump card is turned up, no person must remind his partner to call, on penalty of losing one point.

No honours in the preceding deal can be set up after the trump card is turned up, unless they were before claimed.

If any person calls at eight, and his partner answers, and the adverse party have both thrown down their cards, and it appears that the parties calling have not the honours, the adversaries are entitled, if they please, to compel the play to go on, or to have a new deal.

If any person answers without having an honour, the adversary may consult and stand the deal or not.

## GAMES WITH CARDS.

If any person calls at eight, after he has played, it is in the option of the adverse party to call a new deal.

If any person separates a card from the rest, the adverse party may call it, provided he names it, and proves the separation; but if he calls a wrong card, he or his partner are liable for once to have the highest or lowest card called in any suite led during that deal.

If any person, supposing the game lost, throws his cards upon the table with their faces upwards, he may not take them up again, and the adverse party may call any of the cards when they think proper, provided they do not make the party revoke.

If any person is sure of winning every trick in his hand, he may show his cards, but he is then liable to have them called.

If any person omits playing to a trick, and it appears that he has one card more than the rest, it is in the option of the adversary to have a new deal.

Each person, in playing, ought to lay his card before him; and if any of the adversaries mix their cards with his, his partner may demand each person to lay his card before him, but not to inquire who played any particular card.

### Hints to Learners.

1. Lead from your strong suite (or that with which you could make the most tricks), and be cautious how you change suites.
2. Lead through an honour, when you have a good hand—that is, cause your adversary on the left to lay down a good honour—in order that it may be taken up if possible by your partner.
3. Lead through the strong suite of the left-hand adversary, and unto the weak of him who is on the right; but not in trumps, unless you are strong in them.
4. Lead a trump if you have four or five, or a strong hand; but not if weak.
5. Sequences are eligible leads, and begin with the highest.
6. Follow your partner's lead, but not your adversary's.
7. Do not lead from ace queen or ace knave.
8. Do not lead an ace unless you have the king.
9. Do not lead a thirteenth card unless trumps are out.
10. Do not trump a thirteenth card unless you are last player, or want the lead.
11. The third to play always to put on his best card.
12. When you are in doubt, win the trick.
13. When you lead small trumps, begin with the highest.
14. Do not trump out when your partner is likely to trump a suite.
15. Having only a few small trumps, make them when you can.
16. Make your tricks early, and be cautious how you finesse.
17. Never neglect to make the odd trick when in your power.
18. Never force your adversary with your best card, unless you have the next best.
19. If you have only one card of any suite, and but two or three small trumps, lead the single card.
20. Always endeavour to keep a commanding card to bring in your strong suite.
21. When your partner leads, endeavour to keep the command in his hand.
22. Always keep the card you turned up as long as you conveniently can.
23. If your antagonists are eight, and you have no honour, play your best trump.
24. Always take care to reckon and amend the score at conclusion of each deal; and do not speak or attempt to converse unless between the deals.

A *rubber*, or rub, generally consists of three games. The parties who have two out of the three win the rub. If the same party gain the first and the second game, that concludes the rub, without playing the third.

A rubber also consists of five points. If a party wins the game before the adversary has scored five, he is said to have won a *double*, or two points. Two games won in this manner count four points, and consequently concludes the rubber, for which one point is also reckoned. When an adversary has scored five or more at the termination of the game, you have won only a *single*, which counts but as one point.

Whist is sometimes played by three persons, the fourth place being termed *dumby*. The cards for dumby are exposed on the table, and played by one who undertakes to act as dumby's partner throughout. This method of playing very much destroys the interest of the game, and is never resorted to but in cases of necessity, when four persons cannot be had.

### CRIBBAGE.

This game is played with the whole pack of cards, and by two, three, or four persons, as the case may be. When there are three, they play as individuals; when four, two play as partners, as in the case of whist. The value of the cards in cribbage is the same as in whist; but there are no trumps, excepting the knave of the suite turned up. There are different modes of playing,

according to the number of cards dealt; the number is generally five or six. The game consists of sixty-one points, and to keep score or reckoning, an apparatus called a cribbage-board is employed. This board possesses holes for the scoring of each party, and the scoring is effected by means of pegs. The party who is able to bring his peg into the last hole first wins the game.

The following is an explanation of terms generally used in the game:—

*Crib*, the cards laid out by each party; and whatever points are made by them, the dealer scores.

*Pairs* are two similar cards, as two aces or two kings. They reckon for two points, whether in hand or playing.

*Pairs royal* are three similar cards, and reckon for six points, whether in hand or playing.

*Double pairs royal* are four similar cards, and reckon for twelve points, whether in hand or playing. The points gained by pairs, pairs royal, and double pairs royal, in playing, are thus effected: your adversary having played a seven, and you another, constitutes a pair, and entitles you to score two points; your antagonist then playing a third seven, makes a pair royal, and he marks six; and your playing a fourth is a double pair royal, and entitles you to twelve points.

*Fifteens*.—Every fifteen reckons for two points, whether in hand or playing. In hand, they are formed either by two cards, such as a five and any tenth card, a six and a nine, a seven and an eight; or by three cards, as a two, a five, and an eight, &c. And in playing thus, if such cards are played as make together fifteen, the two points are to be scored towards the game.

*Sequences* are three or four, or more successive cards, and reckon for an equal number of points, either in hand or playing. In playing a sequence, it is of no consequence which card is thrown down first, as thus: your adversary playing an ace, you a five, he a three, you a two, then he a four, he counts five for the sequence.

*Flush* is when the cards are all of one suite, and reckons for as many points as cards. For a flush in the crib, the card turned up must be of the same suite as those in hand.

*The go* is gained by the player when no other number can be played under thirty-one, in which case he takes one; but if the number makes thirty-one, he takes two. The turn-up card accounts in with both hand and crib.

### Regulations for Playing.

1. In dealing, the dealer may discover his own cards, if he pleases, but not those of his adversary. If he does, that adversary is entitled to mark two points, and call a fresh deal, if he pleases.
2. If the dealer gives his adversary too many cards, the adversary may score two points, and also demand another deal, provided he detects the error previous to his taking up his cards.
3. When any player is observed to have in his hand more than the proper number of cards, in that case the person who discovers it may mark four points to his game, and call a new deal, if he thinks proper.
4. If the dealer gives himself more cards than he is entitled to, the adversary may score two points to his game, and call a fresh deal, if he thinks proper: if he does not, he is entitled to draw the extra cards from the dealer's hands. If the non-dealer observes his adversary has more cards than are his due, after they are taken off the table, he may score four points to his game, and call a new deal.
5. If either party meddle with the cards from the time they are dealt until they are out for the turn-up card, his adversary is entitled to score two points.
6. If any player scores more than he is entitled to, the other party has a right not only to put him back as many points as were so scored, but also to score the same number to his own game.
7. If either party touches over his own pegs unnecessarily, the adversary may score two points to his game.
8. If either party take out his front peg, he must place the same behind the other.
9. Either party scoring a less number of points than are his due, incurs no penalty.
10. Each player has a right to pack his own cards; and should he place them on the pack and omit scoring for them, whether hand or crib, he must not mark for them afterwards.

## CHAMBERS'S INFORMATION FOR THE PEOPLE.

### FIVE-CARD CRIBBAGE.

Proper cribbage is played with five cards, and we shall give a description of it in reference to two persons.

After the dealer has been determined by cutting, as in whist, they are dealt one alternately, to the extent of five for each individual. The elder hand takes three points on the board. Each player then proceeds to lay out two of the five cards for the crib, which always belong to the dealer. In doing this, always recollect whose crib it is, as the cards which may advantage your own are almost invariably prejudicial to your game when given to your adversary. This done, the non-dealer cuts the remainder of the pack, and the dealer turns up the uppermost. This card, whatever it may be, is reckoned by each party in hand or crib. When it happens to be a knave, the dealer scores two points to his game.

After laying out and cutting as above-mentioned, the eldest hand plays any card, which the other endeavours to pair, or to find one, the points of which, reckoned with the first, will make fifteen; then the non-dealer plays another card, trying to make a pair, or pair royal, and so on alternately till the points of the cards played make thirty-one, or the nearest possible number under that.

When the party whose turn it may be to play cannot produce a card that will make thirty-one, or come in under that number, he then says 'go' to his antagonist, who thereupon is to play any card he has that will come in to make thirty-one, if he can, and take two points, or to score one for the end hole; and besides, the last player has often opportunities to take pairs or sequences. Such cards as remain after this are not to be played; but each party having, during the play, scored his points gained, in the manner as hereafter directed, proceeds, the non-dealer first, then the dealer, to count and take for his hand and crib as follows, reckoning the cards every way they possibly can be varied, and always including the turned-up card:—

For every fifteen, two points; for every pair, or two of a sort, two points; for every pair royal, or three of a sort, six points; for every double pair royal, or four of a sort, twelve points; for every sequence of any sort, according to the number; for every flush, according to the number; for every knave or nobby of the same suite as was turned up, one point; but when turned up it is not to be reckoned again, nor is anything to be taken for it when played.

Three cards of the same suite in hand entitle the holder to reckon that number, and five for the crib when the turned-up card happens to be of the same suite.

It is always highly necessary, in laying out cards for the crib, that every player should consider not only his own hand, but also whom the crib belongs to, and what is the state of the game; because what might be proper in one situation would be extremely imprudent in another.

If you should happen to possess a pair royal, be sure to lay out the other two cards for either your own or your adversary's crib, except you hold two fives with the pair royal; in that case it would be extremely injudicious to lay them out for your adversary's crib, unless the cards you retain insure your game, or your adversary being so near home that the crib becomes of no importance.

It is generally right to flush your cards in hand whenever you can, as it may assist your own crib or baulk your opponent's.

Endeavour always to retain a sequence in your hand, and particularly if it is a flush.

Always lay out close cards, such as a three and four, a five and six, for your own crib, unless it breaks your hand.

As there is one card more to count in the crib at five-card cribbage than there is in hand, be sure to pay great attention to the crib, as the chance of reckoning more points for the crib than are in hand is five to four.

For your own crib, always lay out two cards of the

same suite, in preference to two of different suites, as this will give you the chance of a flush in the crib.

Never lay out cards of the same suite for your adversary's crib.

Endeavour always to baulk your opponent's crib. The best cards for this purpose are a king and an ace, a six, a seven, an eight, a nine, or a ten; or a queen with an ace, a six, a seven, an eight, or a nine; or any cards not likely to form a sequence.

A king is generally esteemed the greater baulk; as, from its being the highest card in the pack, no higher one can come in to form a sequence.

Never lay out a knave for your adversary's crib, when you can possibly avoid it, as it is only three to one but the card turned up is of the same suite, by which he will obtain a point.

Even though you should hold a pair royal, never lay out for your adversary's crib a two and three, a five and six, a seven and eight, or a five and any tenth card. Whenever you hold such cards, observe the state of your game, and, particularly if it is nearly ended, whether your adversary is nearly out, or within a moderate show, and it is your deal. When this is the case, you must retain such cards as will, in playing, prevent your adversary from making pairs or sequences, &c. and enable you to win the end-hole, which will often prevent your opponent from winning the game.

### THREE AND FOUR HAND CRIBBAGE.

Three and four hand cribbage differs only from two hand in as far as the parties only put out one card each to the crib; and when thirty-one, or as nearly as can be, have been made, then the next eldest hand leads, and the players go on again, in rotation, with any remaining cards, till all are played out, before they proceed to show their hands and crib.

In three-hand cribbage, a triangular board is used, with three lines of holes to allow of each scoring his own game.

### SIX-CARD CRIBBAGE.

Six-card cribbage bears so great a resemblance to five-card, that any one playing the one well must play the other equally so. It consists of pairs, fifteen, sequences, flushes, &c.; and the points are reckoned and marked precisely in the same manner: all the cards must be played out; that is, when either party has made the end hole, the remaining cards in hand must be played, scoring for the pairs or fifteens they may form. When last player, you should endeavour to retain close cards in hand, as they may enable you to acquire four points in playing.

The dealer is supposed to have some trifling advantage.

The dealer is entitled to expect twenty-five points by his hand, crib, and next hand. Thus at his second deal, if his peg is in the twenty-fifth hole of the board, he has his complement of points; the same at his third deal, if he is within eleven points of the game.

If the non-dealer by his first hand attain the eleventh hole in the board, he will have the best of the game; for he is entitled to expect that he shall make his second deal with his front peg in the thirty-sixth hole, and by which he will probably win the game by his hand, crib, and next hand.

If you are dealer, and your adversary has above his complement of points, you must play your game accordingly. Thus, if you have good cards, try to make as many points as possible by pairing, fifteen, &c. On the contrary, if your cards are indifferent, you must play off, to prevent your adversary from obtaining points.

### ALL-FOURS.

This is a game at cards played by two, three, or four persons, with a complete pack of cards. If four, there are two parties, two in each. We shall suppose only two individuals are playing:—

After the cards have been dealt by three at a time, six to each, the dealer turns up the next card as the trump. If your adversary be not satisfied with his hand, he says, 'I beg.' In this case, if you do not

## DANCING.

wish to run the risk of changing the trump, you say, 'I give you one,' and you allow him to score one towards his game. If your own hand be bad, you then deal out three more cards to each, and turn up another trump, which supersedes the former. The adversary may propose to take the chance of dealing three more cards to each, but this can be refused by the dealer, without any forfeiture.

The cards are then played, the elder hand leading, and the party taking up the tricks which he wins. You must either follow suite or trump, if you can.

Ten points make the game, and they are produced by *high*, which is the highest trump dealt; *low*, or the lowest trump dealt; *jack*, or knave of trumps; and *game*, the number of pips on the counting cards. The counting cards are as follows:—ace, four; king, three; queen, two; knave, one; and the ten, which reckons ten. This counting applies to all suites. If the jack be in your hand, secure it as quickly as possible; as, for instance, do not lose an opportunity of trumping with it; for if it fall into the adversary's hand, he reckons it to his game.

Should the card turned up be a knave, the dealer scores one point to his game. Knave of trumps in hand does not reckon, unless you make a trick with it; for if your adversary takes it with the ace, king, or queen, he scores it.

### SPECULATION.

This is a round game at cards, the term *round* meaning that it can be played by a large party round a table. The number most suitable is from seven to thirteen.

The principle of the game is this: A *pool* is formed by the dealer putting two counters, and every other player putting one counter, into a dish or treasury in the middle of the table; and this store is paid to the person who holds the highest trump. Thus it is the object of every person to get the highest trump, and the effort to do so is the *speculation*.

After being duly shuffled and cut, and the dealer determined, he deals three cards to each person, one at a time. These cards must be placed before each person, and no one is allowed to look at them until after the trump is turned. Having finished the deal, the next card determines the trump; this card may be *sold* either before or after being seen. When this speculation is concluded, by some person *purchasing* it with counters, or the dealer retaining it, if he thinks proper, the eldest hand turns his uppermost card, and if this be a superior trump to the one turned, he may also speculate. Each player does the same, till all the cards have been exposed, when the pool is given to the possessor of the highest trump.

### LOO.

Loo is a game played by five or six people; and a pool is made by the dealer putting in five counters. He then deals five cards to each person, and turns up a trump. Whatever suite the trump may be, the knave of clubs, called *pam*, forms the chief. Those who are dissatisfied with their hands can throw up their cards, and demand fresh ones from the pack.

When the ace of trumps is played, it is usual to say, 'Pam, be civil'; the holder of *pam* is then expected to let the ace pass.

When any person holds a flush of trumps with *pam*, this individual can sweep the pool before playing. Then there is a new deal.

The next best hand to the above is trumps only, and this sweeps the pool, if there be not a *pam* flush; and there is also a new deal.

The next best hand is that of a flush of other suites, which sweeps the pool; and there is also a new deal.

When any of these flushes occur, each person, excepting those who hold inferior flushes or *pam*, is *loosed*, and has to pay five counters into the pool.

When none of these flushes occur, and those who wished have changed their cards, the game goes on as at whist, the highest card taking the trick.

When all the cards are played out, they will make but five tricks; and all the counters in the pool are divided between the holders of these tricks, every other person being *loosed*, and obliged to pay five counters to the pool for next deal.

## DANCING.

Dancing, as one of the most healthful and elegant in-door amusements, cannot be too highly recommended. Among a rude or dissolute people, it may degenerate into something worthy of condemnation; but all the blessings of Providence are similarly liable to abuse, and it would be most unjust to condemn a cheerful domestic amusement, merely because it has at times been degraded to immoral purposes. By all physicians, dancing, when pursued in moderation, is recommended as highly conducive to health; and it may be truly said that, allied with music, nothing is more calculated to purge the mind of melancholy, and put the whole temper into good-humour.

Dancing is the poetry of motion. It must be performed with ease and grace, and always with a perfect regard for propriety of movement. As an art, it is taught by professed masters; and one of the leading rules given to the learner is to raise and lower himself gracefully on the elastic part of his feet—that is, the toes; never to leap or come down on the whole sole or heels; also to keep exact time to the music. Dancing is therefore a simple and elegant gliding on the toes, these bending more or less to accommodate the steps, and to prevent everything like harshness of motion. The body should not be held stiffly, and the hands ought to hang down easily by the sides.

Dancing takes the form of several distinct kinds or series of movements, some quick and some slow, and some more complex than others. The most popular of the old-established dances are termed

### Country Dances.

This class of dances takes its name from the French word *contre* (against), from being danced by two parties standing in a row opposite or against each other. The general principle is for each couple in succession to go down the middle of the rows and up again, with some other movements, till all have danced down and into their original places. It is a rule for the top couple to dance down twice, thus leaving the couple that was the second to be at the top. This finishes the dance. If the party wish to dance another dance, the second couple, now at the top, begins, and so on. Thus each couple in the party has the opportunity of choosing any particular dance or tune they may wish. The choice is left to the lady. In general, a party in a country dance do not remain up for more than two dances, when the partners are changed, and new dances begin.

A country dance should not consist of more than twelve or fourteen couples, as it is fatiguing to dance with a greater number. In standing up, the lady should always be on the gentleman's right hand, if they turn their faces to the top of the room. This is a simple rule to determine on which side the ladies and gentlemen should respectively take their places.

The principal figures in country dances are,

1. *Hands across*; that is, the top lady takes the second gentleman by the right hand, and the top gentleman, at the same time, takes the second lady by the right hand, and all go a half-circle round; then all change hands and back again.

2. *Hands four round*; the two top couples join hands, forming a circle; dance half round and back again.

3. *Right and Left*.—In this the top lady gives her right hand to her partner, changing places with him; then her left hand to the person below her, changing places; her partner performs a similar movement, and both return to their places.

4. *Set and change Sides*.—The lady takes hold of both hands of the lady below her, and *sets*—that is, dances for a short time without changing her situation; then

both ladies pass to the gentlemen's side, while the gentlemen pass at their backs to the ladies' side; all again set, and return to their places.

5. *Pousette*.—This signifies that the two top couples respectively join hands, each couple dancing round the other.

6. *Down the Middle*.—The top couple go down hand in hand and return, stopping one couple lower than they commenced.

7.  *Casting off* is the lady going down behind the ladies, and the gentleman behind the gentlemen, and returning to their places.

There are English, Irish, and Scotch country dances; but we know of no distinction among them except the tunes. All vary less or more in their figures. In each, however, as already observed, the plan is followed of the first or top couple dancing with each following couple in succession to the bottom of the room; and as soon as a sufficient number of couples are disengaged at top, another couple commences, and so on through the whole party. The following is an outline of the figures in a few of the more popular country dances. It will be understood that we always refer to what each couple does in succession:—

*Voulez vous Dancer, Mademoiselle*.—Set and change sides, down the middle, up again, and pousette.

*John of Paris*.—Right and left, down the middle, up again, and pousette.

*Captain Fleming*.—Hands across, down the middle, up again, and hands four round.

*The Honeymoon*.—Hands three round on the ladies' side, then on the gentlemen's side, down the middle, up again, pousette, right and left.

*The Triumph*.—Down the middle and up again; then the lady down with the next gentleman; her partner follows: the two gentlemen now lead the lady up between them, taking hold of her hands by one hand, and joining their other hands over her head; pousette.

*Petronella*.—First couple move to the right into the middle, and set; to the right again, and set at the side; to the right again, and set in the middle; to the right again to places; down the middle, up again, and pousette.

*Caper Fey*.—Top couple go down backs and up again; down the middle and up again; set, and turn corners, and reel on the sides.

*The Legacy*.—Hands three round on the ladies' side; then on the gentlemen's side; down the middle and up again; set in the middle, and turn with both hands.

*Sir Roger de Coverley, or the Haymakers*.—Top lady and the bottom gentleman advance to the centre of the dance, turn with both hands, and back to their places; the first gentleman and bottom lady do the same; the top lady and bottom gentleman again advance, turn with the right hand, and back to places; then the top gentleman and bottom lady do the same; top lady and bottom gentleman advance and turn with left hand, and back to places; the top gentleman and bottom lady do the same. The top lady and bottom gentleman advance, the gentleman bows and the lady curtsies; the top gentleman and bottom lady do the same. The top lady and bottom gentleman advance, and pass back to back; top gentleman and bottom lady do the same. The top couple turn, the lady to the right and the gentleman to the left; all the ladies following the lady, and all the gentlemen following the gentleman to the bottom of the room, where they meet their partners and lead up the centre of the room. The top couple then half pousette with each couple, till they reach the bottom of the dance.

Scotch Reels.

These are rapid and rather fatiguing, but not ungraceful dances. They are danced by three, four, five, or six persons; but four is best, and most common. The foursome reel is danced very much according to fancy; the two couples commencing by placing themselves opposite each other, or in a line, with the two ladies in the middle, back to back. In whichever way

the dance begins, the plan is for each person to perform the figure of eight by winding round the others, and setting to partners alternately. The music of course guides the time for the setting and the moving.

Highlanders dance reels with great agility, and are fond of introducing the steps ordinarily called the *Highland Fling*, which is of the character of dancing on each foot alternately, and flinging the other in front and behind the leg which is dancing.

Quadrilles.

These are modern dances of French origin, comparatively tranquil in character, and very suitable for small domestic parties. They are danced by four couples, or eight persons, a couple standing on each side of a square. The lady is always on the gentleman's right.

There are many sets of quadrilles, the figures in each varying from the others; but in by far the greater number of instances one set is adhered to, which is termed Payne's first set. This set, of which we present an outline, consists of four figures, and a finale. The couples at top and bottom first perform a figure; then it is performed by the others; and so on.

*La Pantalou*.—First right and left, set and turn partners; ladies' chain, which is performed by the two ladies giving their right hands to each other, and changing places; then their left hands to the gentlemen, and turn round; and the same back again to places. Now promenade (each couple holding hands crossed) to the opposite side; then half right and left back to places.

*L'Ete*.—The first lady and opposite gentleman advance and retire, dance to the right, then to the left, cross over, lady and gentleman changing places. Dance to the right and left, cross again to their own places, and turn their partners. The second lady and first gentleman do the same.

*Lu Poule*.—The first lady and opposite gentleman cross over, giving their right hands; back again, giving their left and then right to their partners, and set, forming a line; promenade to opposite places. The two who began advance and retire; advance a second time; the lady curtsies and the gentleman bows, and return. The two couples advance and retire; half right and left to their original places.

*La Tremise*.—Ladies' chain; set and turn partners; first couple advance and retire; advance again; the gentleman returns, leaving the lady on the left of the opposite gentleman; the two ladies pass or cross to the opposite side, changing to opposite corners, during which the gentleman passes between them, and sets. The ladies cross over again, and pass to opposite corners, while the gentleman returns to his place, and sets. The first couple set and turn. During these performances, the gentleman at the bottom of the dance stands still. The movement being finished, a similar figure is performed by himself and partner.

*La Finale*.—All eight dance or *chassé across*, changing places with their partners, and set at the corners; back again to places, and set. After this, *L'Ete* is danced, concluding with *chassé across*.

This finale is danced in another way. All eight promenade round the room to their own places. The first and second couple advance and retire; advance again, the gentlemen taking the opposite ladies, or exchanging partners. Ladies' chain; advance and retire; advance again, reclaiming partners, and promenade. This is called the *gallopade finale*.

The preceding embraces nearly all dances usually performed in private parties and balls of an ordinary kind. In the higher class of assemblies, various foreign dances are introduced, such as waltzes, mazourkas, pas seuls, minuets, and gallopades; but of these it is unnecessary to offer any description, as they require careful training under a master. Latterly, a new dance, called the *Polka*, has been introduced; it appears to be a combination of a waltz and an Irish jig, and we should think will never become popular, however fashionable it may be considered.

## ARCHÆOLOGY.

THE term *Archæology*, though sufficiently definite and comprehensive in its original meaning, was confined, until a comparatively recent period, to the study of Greek and Roman art. The word, however, literally signifies the description of ancient things, and it has now been universally adopted in its largest sense to give name to the science which deduces history from the relics of the past.

The recent adoption of this term to characterise the pursuits of the antiquary marks a new era in the study of antiquities, in which it has been reduced to an intelligible and comprehensive system based on philo-epic induction. By this it has been at the same time elevated to its proper rank as a science, and rendered generally acceptable as a popular branch of study. Archaeology, however, is no newly-discovered science. It has its origin in the natural cravings of the human mind to master the secrets of the mysterious past, no less than of the mysterious future: it forms an essential branch of the historian's studies: it enters largely into the inquiries of the ethnologist, or investigator of the various races of the human family; and into those of the philologist, or analyst of their numerous languages. We accordingly find evident traces of an archaeological spirit in the literature of every civilised nation; and generally it exhibits the strongest symptoms of development during periods most marked by rapid progress in the arts of civilisation. It manifested itself at the revival of letters in the sixteenth century, by a return to classic models. Its present tendency throughout Europe seems to be, if not to a total abandonment of these models, at least to a preference for mediæval art, and a desire to carry out its ideas to a more perfect development.

The history of archaeology bears a very near resemblance to that of its elder sister-science, geology, to which, indeed, it has in many respects a close analogy. They are like two successive series of links in the same chain of reasoning, the earliest data of the archaeologist being found exactly where those of the geologist end—in the debatable land of the later alluvial formations. An intelligent geologist, in describing a recent visit to the Newcastle Museum, thus clearly recognises the labours of the archaeologist as applying to the human era the same inductive speculations which his own science treats of in relation to a still earlier state of things:—'As I passed in the geological apartment from the older Silurian to the newer Tertiary, and then on from the newer Tertiary to the votive tablets, sacrificial altars, and sepulchral memorials of the Anglo-Roman gallery, I could not help regarding them as all belonging to one department. The antiquities piece on in natural sequence to the geology; and it seems but rational to indulge in the same sort of reasonings regarding them. They are the fossils of an extinct order of things newer than the Tertiary: of an extinct race—of an extinct religion—of a state of society and a class of enterprises which the world saw once, but which it will never see again. And with but little assistance from the direct testimony of history, one has to grope one's way along this comparatively modern formation, guided chiefly, as in the more ancient deposits, by the clue of circumstantial evidence.'

Such is the rank among the inductive sciences which is at length being justly conceded to the pursuits of the archaeologist. Like the geologist, he deals with records of a period prior to written annals, and traces out the history of ages heretofore believed to be irrecoverable. He deals, it is true, with a recent period, when contrasted with geological eras: but from this he derives the strongest claim to general interest in his pursuits. Intelligent thinkers are shaking themselves free

from the narrow views which induced them to investigate with untiring zeal the natural history of a mammoth or a plesiosaurus, and yet allowed them to despise the equally accessible evidence from whence we may recover the history of our own race. While, however, the rude burial mounds, or the chance revelations of the later alluvial deposits, disclose to us traces of uncivilised tribes to whom we must assign a very remote date, the speculations of the archaeologist, as well as the earliest investigations of the historian, into the records of nations, find their first unquestionable data among the monuments of Egyptian civilisation.

### EGYPTIAN ANTIQUITIES.

The ancient monuments of Egypt arrest attention and impress the mind no less by their intrinsic excellence as the creations of human genius, than by the remote antiquity with which they are associated. We dwell with interest on British monuments of the twelfth and thirteenth centuries, and look beyond that date as into a remote and comparatively unknown era, the memorials of which are mostly crumbled into dust. But on turning to the pyramids, temples, and tombs of Egypt, we look upon the monuments of a people whose civilisation is anterior to the eldest-written records, and whose edifices preserve to us memorials contemporary with the patriarchal age, when the fathers of the Hebrew monarchy dwelt in tents, or groaned under the hard bondage of Egyptian taskmasters.

It may naturally excite surprise that the remotest evidences of civilisation should be discovered on the African continent. All writers, however, who have investigated the subject, agree in assigning an Asiatic origin to the ancient Egyptians. Their features, their language, and many of their peculiarities, clearly point to this. The formation of the skulls of mummies found in the catacombs no less distinctly exhibit the characteristics of the Caucasian variety, which so remarkably contrasts with all the cranial developments of the true African race. We are left to conjecture in assigning that remote period during the infancy of nations, when the first Asiatic colony settled on the banks of the Nile. It suffices, however, for our present purpose to know that, from the ascertained dates of its early history, there can be no doubt Egypt was one of the first countries brought under a fixed social and political system, and where an associated community successfully pursued the arts of civilisation.

The date assigned as the epoch of Menes, or Men, the earliest Egyptian ruler of whom any trustworthy notice has descended to modern times, is about 2000 years B.C.; an era nearly corresponding with the time fixed by Biblical chronologists for the foundation of the kingdom of Assyria by Nimrod, and with the commonly-received commencement of the historic chronology of the Chinese empire. With the solitary exception of the very slight notices recorded in the first eleven chapters of the book of Genesis, all attempts to retrace the records of our race beyond this period have hitherto been based on mere conjecture, unsupported by evidence, although, according to the received chronology of Biblical critics, a period of fully 2000 years intervenes between the era of Menes, the founder of the Egyptian monarchy, and the origin of the human race. Between these two important dates, however, we learn from the Sacred Writings of the destruction of the ancient world by the Deluge, and the recommencement of the human race from one family, according to the accepted chronology, 2348 years B.C.; and about a century later, of the dispersion of the builders of Babel on the plain of Shinar, and the subdivision of the human family into distinct and rival communities. Within

less than two centuries and a-half after this latter event the history of Egypt commences, as a community possessed of political institutions and social arts.

The researches of modern archaeologists have done much to free the early history of Egypt from the fables and inconsistent traditions derived chiefly from the narrations of the priests, and preserved in the writings of Herodotus, Manetho, and others. These placed the era of Menes several thousand years farther back, and furnished a list of intervening kings and dynasties whose history bears the usual mythic characteristics of the traditions of infant nations. Modern research has corrected rather than rejected these historic traditions. It is now thought probable that several, if not the whole, of Manetho's dynasties, which seemed to give countenance to the remote era assigned by the priests to the reign of Menes, were not successive, but contemporaneous, the Valley of the Nile having then been divided into various independent kingdoms. By the labours of Champollion, Wilkinson, and other modern students of Egyptian archeology, aided by recent fortunate discoveries, hereafter referred to, something like a satisfactory chronological series of the kings of Egypt from the time of Menes has been made out. The study, however, is still in its infancy. It dates its commencement within the present century; and its progress has not been accelerated by the excessive zeal of M. Champollion, the professor of Egyptian antiquities in the College of France, who, either from a too sanguine fancy, or from even less creditable causes, announced the discovery of more than any one else has been able to substantiate from the data on which his disclosures are founded. (See No. 55.)

The characteristics of the great Valley of the Nile at once account for its early occupation by the human race, and its becoming the seat of one of the first kingdoms which grew out of the natural tendency of man towards social union. The Valley of the Nile includes, along with the Delta, an area of about 17,000 square miles of cultivable land. The climate during the greater part of the year is salubrious. The annual overflowing of the Nile reduces agricultural operations to little more than the sowing of the seed in spring, and the reaping of the abundant harvest which it yields in an early autumn. While the country is so isolated as to be protected by natural barriers from the ready encroachments of hostile armies, it is most advantageously situated for commercial intercourse with other nations. Hence it is that, after repeated conquests, and under the most tyrannical and oppressive forms of government, Egypt has never become extinct like the great empires of Asia. With some slight amelioration of the suicidal exactions of despotic rulers, it has again and again given evidence of renewed vitality; and holding as it does the real key to the commerce of the East, the indirect and partial command of which was the source of all the greatness of Venice and the Italian republics of the fourteenth century, it can hardly be doubted that Egypt only needs the advantages of social civilisation and free institutions, to resume her ancient place among the empires of the world.

#### Pyramids.

The Pyramids of Egypt, which have attracted the curious traveller for ages, are already so familiar by numerous descriptions and views, that it is hardly necessary, in an epitome like this, to do more than name them, and refer to their gigantic proportions. The two largest of the pyramids of Jizeh are the most stupendous masses of building that human labour has ever accomplished. According to the information communicated to Herodotus by the priests of Memphis, the largest of these was built by Cheops, whom Wilkinson conceives to have been the Suphis of Manetho. Like too many of the evidences of human power and skill, the Great Pyramid remains a monument of tyranny and oppression: 100,000 men were employed during twenty years in its construction; and the great

historian was informed that its founder was interred in a vault beneath the bottom of the pyramid. Some intelligible idea of this vast structure will be conveyed by describing its base as occupying an area almost exactly corresponding to that of Lincoln's-Inn Fields, London, measured to the houses and to the wall of Lincoln's-Inn Garden, while its summit towers to an altitude of 119 feet above the Cross of St Paul's. 'The oldest monuments of Egypt,' says Wilkinson, 'and probably of the world, are the pyramids to the north of Memphis; but the absence of hieroglyphics and of every trace of sculpture, precludes the possibility of ascertaining the exact period of their erection, or the names of their founders. From all that can be collected on this head, it appears that Suphis and his brother Sensusphis erected them about the year 2120 B.C.' The probable uses for which these vast structures were designed have been the subject of much discussion, and repeated attempts have been made to prove their construction for astronomical purposes. The fact, however, of their being found only to contain sarcophagi and their mouldering contents, with the collection alongside of the largest pyramids, of many of small dimensions, and the whole grouping along with catacombs, notoriously constructed as places of sepulture, seem to point them out as the tombs of royal founders. This is still further confirmed by the great care with which the passages to the sepulchral chambers have invariably been found closed up and concealed, so that even now the majority of them appear never to have been entered. (See vignette to No. 55.)

There are numerous pyramids of various sizes in Nubia. The Temple of Belus (the Birs Nimroud of the Arabs) and the Mujelibè at Babylon, were both pyramidal buildings of large dimensions, chiefly constructed of brick, and of which there are still very extensive remains. India, in like manner, furnishes examples of pyramidal buildings still standing in the neighbourhood of Benares. Next to the Great Pyramid of Jizeh, those of Mexico are most calculated to excite attention. Like those of Babylon, the Mexican pyramids are chiefly constructed of bricks. The Great Pyramid of Cholula in Mexico covers an area more than three times the base of the Great Pyramid of Jizeh; but it is built in the usual form of the Mexican pyramids, consisting of four receding platforms, each of which is subdivided into a number of small steps, and the top is left as a large open platform, so that the height of the whole is small when compared with the base. These were designed by the ancient Mexicans as pedestals for the statues of their gods. When Cortez first beheld them, a colossal stone statue occupied the summit of each, covered with plates of gold; but the Spaniards stripped them of their costly coverings, and broke them in pieces. Since then, the lofty terrace of the Great Pyramid of Cholula has been chosen as the site of a church, dedicated to the Lady de los Remedios, in which mass is daily celebrated by a priest of the Indian race, whose ancestors practised there the rites of their idolatrous worship, and sacrificed human victims on the altars of their gods.

#### Architecture.

Previous to the present century, the Pyramids almost invariably attracted the greatest share of attention from those who treated of Egyptian antiquities. The vast and imposing masses of architecture which still remain the chief monuments of Egyptian art, can hardly be said to have received any notice deserving the name of study till the close of last century, when a conquering invader from the 'far west' led the Gothic races of Europe for the first time to the possession of the ancient cradle-land of civilisation, and incited them to victory by the traditional fame of twenty centuries. Since the French invasion, some of the ablest scholars of Europe have devoted themselves assiduously to the study of Egyptian antiquities; and architects have striven to reduce the style of its ancient builders to a system. By such means, the genius of this won-

derful people has only become more fully apparent. Little more had been previously known of Egyptian architecture, except what could be learned from imperfect ideas of the dimensions of the Pyramids, and some general notion of the enormous masses and colossal grandeur of the temples and monolithic monuments. They were generally esteemed solely as the rude evidences of barbaric pomp and power. More careful study has not diminished the wonder with which we regard the gigantic edifices of Thebes or Denderah, and the vastness and solidity of their materials and mode of construction, which seem to bid defiance to time. But in addition to these, Egyptian architecture is now known to be characterised by great elegance in the combinations of its forms; and while in its general features it betrays the probable suggestive source of the Doric temples of Greece, it equally claims comparison with the Gothic styles of mediæval Europe, in the endless variety of its details, and in what may be styled the systematic lawlessness of its proportions. The details of Greek and Roman architecture are reducible to well-defined relative proportions, and their styles admit of variations only by the changing combinations of a few fixed elements. The architects of Egypt, on the contrary, like those of Gothic Europe, created a style wherein powerful and legitimate architectural effects were produced, without its being possible to reduce their plastic elements to any kind of system based on the forms or proportions of any class of features. [For illustrations of Egyptian Architecture, see No. 28, Vol. I.]

One or two attempts have been made to introduce the Egyptian style of architecture into this country, but they have resulted, as was to be anticipated, in utter failures. The vast temples of the Pharaohs, constructed for the worship of ancient Egypt, and adapted to the climate and local peculiarities of the country of their birth, become ridiculous caricatures when reproduced in brick and plaster in the busy thoroughfares of London. The introduction, moreover, of large windows, separate floors, and even shop fronts, with the attendant requisites of modern social habits, make sad havoc with the principles of genuine Egyptian architecture, so that any one who derives his ideas of it from the Egyptian Hall, jammed into the row of brick tenements and smoky chimneys of Piccadilly, will arrive at very unsatisfactory conclusions. The style has been revived with better success in the catacombs of some of our great public cemeteries. But after all, its true use and value is as the record of a race, a faith, and a state of religion, extinct beyond the possibility of revival ages ago. The most enthusiastic antiquary can look with little satisfaction on the imperfect adaptation of the obsolete symbols of a forgotten creed to give expression to the sublime anticipations of the Christian faith.

Hieroglyphics.

By far the most interesting branch of Egyptian antiquities is the hieroglyphics, which a chance discovery of modern times has done more to elucidate than all the unaided labours of the archæologist could ever have effected. From the earliest times, these mysterious symbols have excited an interest fully equal to their value as historic records. The Greeks and Romans, partly from national pride, but still more perhaps from a want of that philological talent peculiar to modern times, appear to have paid little attention to the languages of the *barbarians* with whom they were brought in contact. They made up, however, for their ignorance of Egyptian records by the most comprehensive assertions, on the faith of which it has been believed, almost to our own day, that Egypt was the parent of all the arts and sciences; that the hieroglyphic inscriptions on the public monuments contain a summary of the most important mysteries of nature, and the rudiments of all the knowledge we derive from classic literature. The interpretation of the hieroglyphics formed, it was believed, one of the most sacred

mysteries of the priesthood, which was either purposely concealed, or had already been lost, when the Romans established themselves in Egypt. Since then, though ponderous folios had been written on the subject, some of them professing to explain the whole mystery, nothing was really known of hieroglyphic writing till the invasion of Egypt by Napoleon—if we except the explanation of the *Tau*, or handled cross, the symbol of life, the traditional interpretation of which had strangely survived the oblivion of all else.

In digging the foundations of Fort St Julian, near Rosetta, at one of the mouths of the Nile, the French discovered an inscribed block of black basalt, which, along with the other antiquities secured by the army of Napoleon in Egypt, was brought home to England, and is now familiarly known as the Rosetta Stone. This valuable relic, which forms one of the most interesting features of the Egyptian collection in the British Museum, contains an inscription in three distinct characters—the *Hieroglyphic*, or sacred; the *Enchorial*, or common Egyptian; and the *Greek*. From the terms of the latter, it became immediately apparent that the three inscriptions were versions of the same decree, in the several characters; and this was further confirmed by observing that the hieroglyphic inscription ended with the numerals I. II. and III., where the Greek has 'The first and the second . . .' the remainder being broken away. A key seemed to be at length found to the long-hidden mysteries of Egyptian hieroglyphics, which had mocked the curious gaze of ages with the vain offer of unrevealed secrets. An accurate fac-simile of the three inscriptions was engraved, and extensively circulated by the Society of Antiquaries. The Greek text was translated and discussed by Person and Heyne, the most eminent among the Greek scholars of Germany and England. But there explanation paused; and it seemed as if, after all the high anticipations excited by this discovery, it was to prove altogether fruitless. The causes of this are easily explained. Unfortunately, a considerable part of the hieroglyphic inscription was entirely wanting. The beginning of the enchorial and the conclusion of the Greek inscriptions were in like manner defaced; so that precise points of coincidence were wanting from whence to set out in deciphering the unknown by the known characters. Dr Thomas Young was the first to master any of the unknown hieroglyphics. With great sagacity, he noted the recurrence of certain words, such as Alexander, Ptolemy, &c.; and in corresponding parts both of the enchorial and hieroglyphic inscriptions, he soon detected corresponding groups of characters, and established the important fact, that these proper names are distinguished by the enclosing oval or royal *cartouche*, of such frequent occurrence on all Egyptian monuments. This discovery, however, sufficed to prove that the Greek is not a literal translation of the Egyptian. The names do not invariably recur in corresponding places of the several inscriptions, synonyms or pronouns being substituted for them; so that the Greek cannot be assumed as expressing more than the general meaning of the other inscriptions. This of course greatly detracts from the assumed value of the Rosetta Stone as a key to the hieroglyphics; and though it has now been familiar to the scholars of Europe for nearly half a century, a complete translation of its symbols still remains a desideratum. As an example of hieroglyphic writing, there is here given a representation of an inscription from the obelisk of Philæ. The symbols enclosed within the elliptical ring or cartouche signify the word 'Cleopatra'—there being a phonetic character corresponding to every letter in the Greek name, together with the symbols (a small semicircle and oval) of the

feminine termination. Thus, beginning at the top, and reading from right to left, we have nine signs respectively agreeing with the nine letters K-L-E-O-P-A-T-R-A—the small oval and semicircle on each side of the last bird, or A, marking the feminine termination.

By means of the Rosetta Stone, Dr Young was led to another important discovery, from which it appears that the sacred symbols were used not only as the representatives of things, but also of sounds; so that, by a combination of them as alphabetic characters, such new names as those of the Greek and Roman conquerors are inscribed on Egyptian monuments with the like symbolic writing as those of the ancient Pharaohs. Already history and chronology have received valuable additions from observations based on these discoveries; the royal cartouches have been identified on nearly all the most important Egyptian monuments; and historic traditions, which had been rejected as unworthy of credit, have received unexpected confirmation. The same eminent English scholar above referred to succeeded in deciphering upwards of 200 hieroglyphic symbols; and from the double meaning which these frequently bear, both as symbols and phonetic characters, we discover one important reason for the rude and imperfect mode of *picture writing* being retained by a people far advanced in civilisation, and possessed of a written language in ordinary use. Another, though secondary reason, for this has been overlooked; namely, the value of hieroglyphics as architectural embellishments. That they were frequently used for this sole purpose, is apparent from the introduction of a series of royal cartouches as features of decoration, as on the pillars at Luxor; nor can any one look on a drawing of one of the great temples, or even of an obelisk or sarcophagus, without being satisfied that the hieroglyphics form an essential and important feature of decoration, independent of their value as symbolic or phonetic characters. To the list of hieroglyphics deciphered by Dr Young, M. Champollion and others made considerable additions; and so much confidence is now felt in these interpretations, that during the present year (1849) a movable font of hieroglyphics has been cut in Paris, by means of which the inscriptions of ancient Egypt may be multiplied, and generally distributed, with the same facility as a common handbill. This is certainly not the least wonderful of the results of modern intelligence and inventive skill; and whether or not the treasure prove equal to the long-cherished expectations regarding it, it can hardly be doubted that these Egyptian mysteries will not much longer remain concealed.

In treating of hieroglyphics, those which were in use by the Aztecs, and are still visible on the ancient monuments of Mexico, must not be altogether overlooked. They are much ruder than those of Egypt, and only resemble them in the element of *picture writing* common to both, unless it be added that the Aztecs appear to have made a similar use of the cartouche. This rude substitute for writing appears to have been the only one known to the natives of America. An illustration of the mode of using it in extraordinary cases is given in the account preserved of the Indian scouts, who informed their master Montezuma of the arrival of Cortez and his followers, by sketches of the Spaniards, their ships, horses, firearms, &c.

It is probable that, even should the Egyptian hieroglyphics be thoroughly mastered, the amount of knowledge derived from the inscriptions on the temples and tombs will fall far short of what the patient sagacity of modern archaeologists has already deduced from the paintings and sculptures, and from the actual relics discovered in the catacombs. No features of national manners are found by the archaeologist so well worthy of study as the modes of sepulture, and the relics frequently deposited in the tomb along with the deceased. Among such the catacombs of Egypt occupy a prominent rank. By means of the sepulchral rites of the people, a clue may frequently be obtained to the nature of their religious belief; and this is peculiarly the case

with the Egyptians. The human soul was regarded by them as a direct emanation from the Deity, who himself animated all nature as the soul of the universe; and their dead, therefore, invariably bore some of the emblems, and were bound up so as to resemble the form, of Osiris, the judge of the dead, and the ruler over the world of spirits. It was only those, however, who, by a virtuous life, were fitted for the change, that were immediately after death reunited to their divine source. One of the most frequent subjects of Egyptian painting represents the final judgment of the soul in the presence of Osiris. The actions of the deceased are weighed in the scales of truth. The god Thoth stands as the recording angel noting the result; and if it proves imperfect, the soul is condemned to return to earth, according to the Egyptian doctrine of transmigration, in the form of some unclean animal—most frequently that of a pig—and must endure a purgatorial penance of tedious duration ere it can return to the human form, and again appear before the dread tribunal of Osiris. In addition to this transmigratory doctrine, the Egyptian creed included the idea of a great cycle, at the end of which all things were to return to their former state. It is supposed by some writers that the practice of embalming originated in the desire of preserving the body in a fit condition to receive the soul on its return to inhabit its former dwelling. This, however, is extremely doubtful. Such an idea may have added strength to the popular inclinations when it became ingrafted on to their creed; but it is unquestionable that the same practice continued long after all belief in the ancient mythology of Egypt had ceased; and it is much more probable that it had its origin, like the sepulchral rites of all other nations, in the natural feelings of affection and respect for the dead.

#### ASSYRIAN ANTIQUITIES.

Quitting the antiquities of Egypt, which have attracted the attention of intelligent inquirers from the days of Herodotus to our own, we turn to the magnificent monuments of Assyrian art. These, though probably contemporaneous with the sculptures of Thebes and Memphis, have been explored almost for the first time by the indefatigable traveller Austin Henry Layard, who has already had the satisfaction of seeing the first fruits of his labours deposited in the British Museum, before returning to the scene of his singularly interesting excavations on the banks of the Tigris. Within the vast mounds to which a faithful tradition has attached the name of Nimrod the mighty Hunter, our indefatigable countryman has discovered monuments of ancient art and imperial magnificence which amply justify the title that has for ages associated it with one of the earliest settlements of the human race. Though completely distinct in character and style from the monuments of Egypt, these relics of old Assyrian art still present such affinities to them as might be anticipated from the productions of contemporaneous races and creeds somewhat similarly situated as to climate and locality. Like the ibis and hawk-headed deities of Egypt, the Assyrian marbles present frequent repetitions of the eagle or vulture-headed god—a human form conjoined with the head of a bird of prey. Among the sculptures of both countries the sphinx occurs. Not greatly dissimilar in character, and akin to it, are those most remarkable monuments of Assyrian arts and mythology—the colossal human-headed lions and bulls—which the wild Arab sheik, who witnessed their exhibition, pronounced to be 'the idols which Noah cursed before the Flood!' On the discovery of the winged human-headed lions (see fig.), Mr Layard was filled with admiration and delight. 'These magnificent specimens of Assyrian art,' he remarks, 'were in perfect preservation; the most minute lines in the details of the wings and in the ornaments had been retained with their original freshness. I used,' adds the enthusiastic traveller, 'to contemplate for hours these mysterious emblems, and muse over their intent and history. What more noble forms could have ushered the people

## ARCHÆOLOGY.

into the temples of their gods! What more sublime images could have been borrowed from nature by men who sought, unaided by the light of revealed religion, to embody their conception of the wisdom, power, and

ubiquity of a Supreme Being! They could find no better type of intellect and knowledge than the head of the man; of strength than the body of the lion; of ubiquity than the wings of the bird. These winged human-headed lions were not idle creations, the offspring of mere fancy; their meaning was written upon them. They had awed and instructed races which flourished three thousand years ago!

It may suffice to add, that these wonderful monuments of Eastern art are generally covered with inscriptions in the cuneiform or arrow-headed character, which now furnish a no less interesting subject of earned investigation than the hieroglyphics of the Egyptian monuments, and give promise of no less valuable disclosures. To facilitate this, these primitive Assyrian characters have been reproduced by the skill of English workmen in a complete font of movable types, so that copies of all such cuneiform inscriptions is may be discovered can now be multiplied and distributed to any extent.

Many of the Assyrian monuments referred to consist of slabs sculptured in low relief, and still bearing traces of the bright colours with which they were originally decorated. They recall in a striking manner the allusion to the images of the Chaldeans by the prophet Ezekiel, written not many years before the gorgeous empires of Assyria were buried in the desolate heaps on the banks of the Tigris; from whence, after the

lapse of so many centuries, they have been exhumed by a wanderer from the remote and unknown British Isles. The Hebrew prophet, referring to the sins of Jerusalem, says, 'She doted upon the Assyrians . . . ; for when she saw men portrayed upon the wall, the images of the Chaldeans portrayed with vermilion; girded with girdles upon their loins, exceeding in dyed attire upon their heads; all of them princes to look on, after the manner of the Babylonians of Chaldea, the and of their nativity: she doted on them,' &c. Though the character of these early monuments of Assyrian art is entirely distinct from those of Egypt, Mr Layard's interesting excavations have brought to light curious evidences of the intercourse between Egypt and Assyria; and farther investigations can hardly fail to throw ad-

ditional light on this new chapter in the history of early nations.

### ANTIQUITIES OF HINDOOSTAN.

The cave temples of Elephanta and Ellora, and the numerous ruined temples scattered throughout the Indian empire, form another most interesting branch of monumental remains connected with one of the early races of the human family. Certain general resemblances are traceable among all these relics of Eastern art and ancient mythology. Much undue weight, however, has frequently been attached to this, as though it pointed to some intimate intercourse or great similarity in faith and manners among those widely-separated races. The worship of the cow, both in ancient Egypt and in India, has frequently been referred to as conclusive evidence of an intimate connection between the religions of these two countries. During the war in Egypt some sepoya of our Indian army, who crossed from the Red Sea to the Nile, were attracted, on their visit to the temple of Dendera, by the sculptured representation of the cow of Athor, and immediately prostrated themselves before it. This has been regarded by several writers as triumphantly proving the kindred character and common source of the two creeds; but the argument will not stand close investigation. Had the Indian sepoya been arrested by some of the arbitrary and unintelligible symbols of Egyptian hieroglyphics, which possessed to them a sacred meaning, some importance might justly be attached to it; but the selection of the cow by two agricultural nations as a sacred symbol, may admit of very easy explanation without supposing them to have had any previous intercourse. Mr James Fergusson, the most recent investigator of the antiquities of Hindoostan, after personally examining the architectural remains of Egypt and India, denies that they have any essential features in common; and all the latest inquiries into the subject of Indian antiquities seem to lead to the conclusion, that the ideas which have been so generally received of the immutability of the Hindus, and the primeval antiquity of their remains, have been based on theories unsupported by evidence. Already the colossal elephant which gave name to Elephanta has progressed so rapidly to decay, as to excite just doubts of its great antiquity at the time of its discovery; and if the general diffusion of the religion of Buddha in India is correctly fixed at a period little more than 150 years a.c., it is obvious that the remains of temples dedicated to that religion must no longer be classed along with those of Egypt. Mr Fergusson assigns them a far more recent date than even this might imply. He has carefully studied them, and made drawings of their various details; and in his 'Picturesque Illustrations of Ancient Architecture in Hindoostan,' he advances the opinion that the most ancient of the cave temples are not many centuries old. India, however, has undoubtedly formed an early seat of civilisation; traces of which are apparent both in the faith and the manners of the more ancient races that still occupy the country, though these are much too slight to justify many of the arguments that have been deduced from them. Impressed, indeed, as all European thinkers are, with the influence of religious opinions which have been slowly developing their powers during many centuries, they are too ready to take for granted the same slow development in judging of Eastern creeds. Recent investigations prove, on the contrary, that the religion of the Sikhs, and those of many other Indian sects, have sprung up and been adopted by whole races almost in our own time.

### THE CELTS.

The whole investigations of the archæologist into the remains of the ancient occupants of Europe, tend to confirm the idea derived from the sacred records, that we must look to the East as the cradle of the human race. The Celtic, the Sclavonian, and the Teutonic races, whose descendants, distinct or intermingled, now

people nearly the whole of Europe; and even the Zingali, or wandering gipsies, who are scattered without being incorporated among them, are but successive waves of the same great tide of population which has gradually flowed onward towards the north-west, until, like a pent-up flood, it has at length overflowed its ancient barriers, and is peopling the new world of America with these same descendants of the early nomadic tribes of Asia.

It is in tracing out the annals of these aboriginal races that the labours of the archaeologist are chiefly productive of valuable results, deciphering what may be termed the unwritten history of man, and bringing to light the lost records of our earliest ancestry. The investigations of the archaeologist carry us back at once to a period of which history takes no note, placing before us clear and intelligible records of the character and habits, and of the amount of civilization of the aboriginal tribes of Europe and the British Isles, many centuries before the Romans carried the arts of peace in the train of their conquering legions.

Intelligent chronologists have thought themselves successful in tracing the passage of the Celts towards the western parts of the old world 2100 years before Christ; and Hirtzian, an able archaeologist, in treating of the Celtic Druids, has brought forward evidence, founded on their astronomical knowledge, to prove their colonisation of Britain about 1600 years before the Christian era. This curious calculation is based on the knowledge we possess of the religious festivals of the Druids, the dates of which were affected by that slow movement of the seasons through the signs of the zodiac caused by the precession of the equinoxes. The direct archaeological evidence which may be brought to bear on the subject, confirms such speculations by proving the existence of a native population in Britain at a very early period.

Such speculations are possessed of peculiar interest and value. If the dates of this remote chronology can be established, they enable us to connect the infant history of our own country with the great historic nations of antiquity, and lead us to this striking chronological coincidence, that just about the time when the patriarch Jacob journeyed into Egypt to behold his long-lost son, the nomadic Celts were crossing the English Channel, and peopling the savage coasts of the British Isles. It gives new life to our ancient annals, long buried in fable and error. We behold in idea the British Druids raising their ponderous altars and temples amid our northern forests, while the priests of Isis were consecrating on the banks of the Nile the giant monuments of ancient Thebes, and while the great Jewish lawgiver was setting up the pillars of the twelve tribes in the wilderness of Sinai.

The evidence from whence we trace the records of the Eastern wanderers who first disputed with the wolf and the wild boar of the primeval forest their right to the uncultivated soil of our insular home, while it confirms such curious speculations, also satisfies us that these rude aboriginal tribes were almost destitute of any rudiments of the arts of civilisation. In Denmark, in Ireland, and in the north of Scotland, the evidences of this primeval race abound to a degree unknown in other parts of Europe, where the wave of Roman invasion has obliterated many of the traces of aboriginal occupants. But it is in number and variety chiefly, and not in any peculiarity of characteristics, that the Celtic antiquities of these countries are distinguished from those of the rest of Europe. The similarity, indeed, which is discoverable in the Celtic remains not of Europe only, but of Asia, place the fact beyond doubt, that in treating of the British aborigines, we are referring to the same races whose relics can still be traced on the vast plains of Central Asia.

Within the last few years tumuli have been frequently opened in the neighbourhood of the Black Sea, resembling in every respect those of the earliest and rudest character which are found on the downs of Wiltshire, or scattered over the Orkney Islands, and

furnishing evidence of temporary locations of the migratory tribes which ultimately crossed the English Channel, and first peopled the British Isles. In treating, therefore, of the archaeology of Great Britain and Denmark, we refer, to a great extent, to what they possess in common with the rest of Europe.

#### BRITISH ARCHAEOLOGY.

The evidences we possess of the national character and habits, and of the various degrees of civilization of the aborigines of Great Britain, are derived from their ancient dwellings and sepulchres: from cromlechs, barrows, cairns, and tumuli; from their weapons, ornaments, and pottery; and from the remains of their boats and agricultural implements. Remote as is the period the history of which it is sought to recover, the evidence on which we have to reason is neither scanty nor isolated. Scattered over the uncultivated downs of England and Scotland, there still remain numerous examples of the rude dwellings of our barbarian ancestry which have escaped the wasting tooth of centuries, or the more destructive inroads of the plebs, and afford abundant indications of the barbarism with which surrounded the homes of our forefathers. On the Yorkshire moors, on the extensive plains of Wiltshire, on the Sussex downs, and even on the cultivated hills of Surrey, as well as in Aberdeenshire, Morayshire, and the Shetland and Orkney Islands, the ruined dwelling of the ancient British savage still speak to us in an uncertain language of the unskilled and simple condition in which he lived.

#### I. THE STONE PERIOD.

Subdividing into periods, which are warranted by reality and convenience, we shall advert first to the

#### Pit and Cave Dwellings.

Sir Richard Colt Hoare, in his valuable work on ancient Wiltshire, remarks—'We have undoubted proofs, from history and from existing remains, that the earlier habitations were pits, or slight excavations in the ground, covered and protected from the inclemency of the weather by boughs of trees and sods of turf.' These locations are almost invariably found in groups, showing the gregarious and social habits of man in the rudest stage; but the low state of their occupants, physically and mentally, is apparent from the character of the simple dwellings. They consist of mere excavations in the earth, of a circular or oblong form, and averaging about eight feet in diameter. They are excavated generally about three feet below the surface, and surrounded with a raised edge, and where an opening is left, which no doubt served for door and window, and probably for chimney also. On digging in the centre of these pit-dwellings, several charred wood are found, the evidences of their domestic fires; and with them occasionally flint arrow-heads mixed with bones and other refuse, indicating the connection with the earliest race whose weapons are known to us. The ancient names of some of these primitive locations, such as that of *Pes Pits* in Wiltshire, retain an evident allusion to their character.

Another class of dwellings, examples of which still remain, may be considered as the earliest improvement on these primitive lairs. They also consist of pits, but edged with stones, and occasionally accompanied with small circular field enclosures, as if indicating the rudiments of a pastoral life—the folding of sheep or cattle. The use of stone in the construction of their dwellings appears to have led to extensive changes in the habits of the early Britons: but it is curious to find that in this advanced stage the dwellings are still subterranean; while some of them are on so large a scale, as to suggest the probability of their being adapted to the habits of a people who sheltered themselves, like the Esquimaux and the Greenlanders, from the inclemency of a northern winter. An account of very curious and little-noticed remains of this class in Aberdeenshire is preserved in the 'Archæologia Scotica,' vol. 2.

These consist of a number of subterranean habitations, spread over a district of nearly two miles in diameter. The situation had originally been a forest, as appears from many large trunks of trees still dug up there; but it is now a dry moor. The roofs of these dwellings have been uncovered from time to time by the ploughshare striking against them. The entrance to them appears to have been between two large stones, placed in a sloping direction at one end, between which the entrant has to slide to a depth of about six feet, when he finds himself in a large vault, occasionally upwards of thirty feet long, and from eight to nine feet wide. Upwards of fifty such subterranean dwellings have been found in one district. The walls incline inward, so as to approach the form of an arch; and across these are laid large stones, some of them five and six feet in length, and above a ton in weight. Where the ground in the neighbourhood of these ancient cave dwellings has escaped the inroads of the plough, small earthen enclosures, similar to the ruder pit dwellings already described, are almost invariably found near them, having no doubt formed the summer habitations of the constructors of these massive subterranean retreats.

Tumuli, Barrows, and Cairns.

The raising of mounds of earth or stone over the remains of the dead is a practice which may be traced in all countries to the remotest times. The simplest idea that can be suggested to account for its origin is, that as the little heap of earth displaced by the interment of the body would become the earliest monument by which survivors were reminded of departed friends, so the increase of this by artificial means into the form of the gigantic barrow would naturally suggest itself as the first mark of distinction to the honoured dead. To this simplest construction the term *barrow* should be exclusively reserved, while the *tumulus* is distinguished by its circular form. The latter name, however, includes a considerable variety. Sir Richard Colt Hoare has distinguished fourteen different kinds of barrows. Among these he includes the pond barrow, which was certainly not sepulchral, but should be classed with the pit dwellings already described. Others of the distinctive features marked by him are such slight or rare variations from the ordinary type, that their recognition, as essentially differing from the others, only tends unnecessarily to complicate the inquiry. The following are the most marked and distinct, their names indicating their shape:—1. The cone barrow; 2. The bell barrow; 3. The bowl barrow; 4. The female barrow, called by Stukely the Druid barrow. It is slightly elevated, and enclosed with a vallum, or wall of earth, and its usual contents seem to justify the name here assigned to it. 5. The twin barrow, which consists of two conical mounds enclosed by a foss, one of them being generally larger than the other. The others are more or less modifications of these forms and arrangements, and no such peculiarities in their contents have yet been observed as to justify their being regarded as essentially distinct.

The *cairn* is only another and more artificial form of the tumulus, and is frequently found in combination with the latter. Silbury Hill, near Marlborough in Wiltshire, is the largest tumulus in Britain, and probably in the world. This vast artificial conical mound of earth measures 2027 feet in circumference, it covers an area of five acres and thirty-four perches of land, and its perpendicular height is 170 feet. The immense labour required in order to explore the contents of this huge pile, long preserved it from the investigations of the antiquary, though forming the most remarkable object of its class, and occupying a place among the Celtic monuments of Wiltshire, where antiquarian research has been conducted with a degree of zeal and intelligence worthy of earnest scientific investigation. At length, during the present year (1849), the Archaeological Institute of Great Britain and Ireland accepted of an invitation from the citizens of Salisbury to hold their annual congress in that ancient cathedral town.

The barrows of the Wiltshire downs, so long the objects of Sir Richard Colt Hoare's diligent and successful researches, naturally formed a prominent object of investigation; and it was determined that the long-buried mysteries of Silbury Hill should at length be explored. A tunnel was accordingly opened in the side of the hill, and carried on till it had nearly reached the centre, when the operations of the excavators were suspended until the arrival of the members of the Institute. When the work of excavation was resumed, the tunnel was carried to the very centre of the hill, a distance of 144 yards from the entrance, but without any discovery being made. It had been thought exceedingly probable that the mound might prove internally to consist chiefly of an artificial structure of stone; a cairn, in fact, covered over with earth, as has been found to be the case in some of the largest tumuli hitherto opened. When the excavation had proceeded so far as completely to disprove this, it was still confidently anticipated that, on reaching the centre, a cromlech or kistvaen would be found, with its usual sepulchral contents, and most probably accompanied with relics of corresponding importance to the magnitude of the superincumbent earth-pyramid. All these speculations, however, have proved to be unfounded, though it is still possible that, before the search is abandoned, the kistvaen, which was supposed to lie concealed within this vast tumulus, may be found, contrary to the wonted custom in these ancient sepulchral mounds, at some distance either above or below the natural surface of the ground. The research, so far as it has proceeded, has at least sufficed to show that neither the cromlech nor the cairn must be invariably looked for in the larger tumuli.

The most remarkable monument of the latter class is that of Newgrange, another large artificial mound, or rather cairn, in the county of Meath, near Drogheda. This Celtic monument presents the appearance of a hill about 400 feet in diameter, and about 70 feet high, the top of which is covered over with a luxurious growth of trees. So early as the year 1699, some labourers employed in removing stones for the repair of a neighbouring road, accidentally discovered an opening into a passage formed of large, upright, and horizontal stones, which communicates with three large chambers similarly constructed in the centre of the mound. This remarkable tumulus was explored and minutely described by Governor Pownall in 1770. The roof and walls of its chambers are curiously ornamented with rude carvings; and within these recesses were found large stone urns or basins, which still remain. 'It would be in vain,' says Mr Wakeman, an Irish antiquary, in describing the cairn of Newgrange—'it would be in vain to speculate upon the age of a work situate upon the banks of the Boyne, which, if found upon the banks of the Nile, would be styled a pyramid, and perhaps be considered the oldest of all the pyramids of Egypt.' Undoubtedly the whole class of Celtic tumuli and cairns may justly be reckoned as belonging to the same order of monumental erections, of which the Egyptian pyramid is the most perfect form.

Duns, Borghs, Vitrified Forts, &c.

Next to the sepulchral monuments of remote ages, their fortifications form the most durable, as well as the most characteristic evidences of their skill and degrees of civilisation which remain to us. The construction of offensive and defensive weapons is the very earliest proofs which the rude and solitary savage affords of that intelligence and design which distinguishes him from the brutes. This is succeeded by the domestic and social relationships from whence spring society, ranks, laws, and all the primary elements of civilisation. Among the first evidences of such progress is the union for mutual defence, and the construction of strongholds for the safety of the community, and the protection of their goods when threatened by invading foes. The summits of numerous hills in Scotland, Ireland, and Wales, retain traces of ancient

hill forts of various descriptions, from the rude earthen ramparts of the circular dun, to the elaborately-constructed borgh, or stone fort, which is still to be found, chiefly in the Orkneys and Western Isles. Some of the simplest earthen duns, consisting of a round or oval earthen wall and ditch, surmounting a rising ground, may be presumed to be the work of the same rude architects who occupied the pit dwellings, and constructed the earthen cattle folds already described. Rapid progress, however, would be made in the indispensable art of military engineering. Every unsuccessful defence of such strongholds, and every assault on their feeble ramparts, would very naturally suggest the necessity for more effective fortresses, and we accordingly find examples of them, which have escaped the inroads of the plough, exhibiting considerable progress in the art of fortification.

One of the most interesting examples of the ancient British hill fort is the White Caterthun, constructed on the summit and around the sides of a conspicuous hill in Forfarshire, situated about five miles north of Brechin. It is of an oval form, composed of an immense dike of loose white stones, the enclosed area of which is 436 feet in length, and 200 feet in breadth. Outside of this wall is an earthen rampart and ditch, and about 100 yards lower down, the remains of another double rampart and ditch are visible. Within the centre area are the foundations of a rectangular building, and a hollow, now nearly filled with stones, which appears to have been the draw-well of the garrison. The literal translation of *catter-thun* is *camp town*; and it may be added that it forms one of the various native strongholds which have been conjectured to be the camp of Galgacus, the leader of the Caledonian host which attempted to withstand the Roman invaders in the famous engagement with Agricola.

Similar in character to these latter strongholds are the more celebrated vitrified forts of Scotland, which have formed the subject of so much antiquarian controversy since attention was first drawn to them by Mr John Williams in 1777. This intelligent observer was employed by the trustees of forfeited estates, in 1773, to superintend some operations in the Highlands in his capacity of a civil engineer; and his attention was called to some of these singular remains which he fell in with in the localities he had to visit. He accordingly published, about four years afterwards, a treatise on the subject, entitled 'An Account of some Remarkable Ancient Ruins, Lately Discovered in the Highlands and Northern Parts of Scotland.' In his preface, the author remarks that his discovery was esteemed so extraordinary, that it was generally looked upon as a fiction, and no London publisher could be found to undertake its publication. Mr Williams was the first to apply to these singular structures the name *Vitrified Forts*; and though the idea of their artificial construction was almost immediately disputed by various able writers, who attempted to assign to them a volcanic origin, further investigation has abundantly proved the justness of Mr Williams's descriptive term.

In consequence of the frequent controversies on the subject of vitrified forts, and their very unsatisfactory results, the Society of Antiquaries of Scotland directed special attention to it in the year 1825; and a series of observations, made chiefly under the direction of Dr Samuel Hibbert, one of the secretaries, and since published in the 'Society's Transactions,' have furnished a valuable mass of information on the subject, the result of which may be thus stated:—Dr Hibbert arrives at the conclusion that the vitrification was no part of the process of erection, but resulted accidentally, from the frequent kindling of fires at particular spots, and chiefly from the ancient beacon-fires, which formed the constant signals of war and invasion in Scotland from the remotest ages down to the period of the Union. Dr Hibbert, accordingly, rejects the name of *Vitrified Forts*, preferring that of *Vitrified Sites*, as more correctly descriptive of these ancient remains, many of which he conceives were only enclosures intended for

the protection of beacon-fires. The only argument which tends to throw any doubt on the result of these careful researches is that of Dr Macculloch, who affirms that, in situations where the most accessible materials for constructing a stone fort are such as are incapable of being vitrified, suitable materials have been selected and brought with great labour from a distance. Further information is, however, needed to confirm this point. Granite, porphyry, limestone, sandstone, and what is called puddingstone, are all more or less easily fusible by fire, and capable of being reduced to the vitreous state of the materials found in these singular erections, when mixed with the accumulated ashes of burned wood as a flux, and repeatedly exposed to fire. The prevalence of one or other of these fusible materials in almost every district of Scotland, renders exceedingly doubtful any opinions founded on the argument of Dr Macculloch, or the evidence it would afford of the practical skill and ingenuity of the ancient Caledonian. We shall see, however, that the arts of the native Briton, as well as of the ancient tribes of Northern Europe, included at a very remote period that of smelting ores and working in metals; so that the fusing of their castellated ramparts, for the purpose of more effective defence, is not at all inconsistent with their other acquirements.

The borghs or circular stone forts which abound in the northern and western isles of Scotland belong to a later period than the ancient British duns, and are most commonly ascribed to Danish invaders. They consist of circular structures, tapering towards the top, built of unhewn stones, and constructed without the use of cement; within the outer wall, which inclines inward from its tapering form, an inner perpendicular wall is attached to it by large cross stones, which form a series of flights of stairs, lighted by loopholes which look into the central area.

A class of buildings bearing a singular resemblance in some respects to the Scottish borghs are the *Nuraghes* of Sardinia, first described by M. Petit-Radel, in a work published at Paris in 1826. The largest of these singular erections are more complicated than the Scottish borgh, consisting of a circular central tower, tapering towards the top, and flanked at four points by smaller towers, united by a solid mass of masonry, which forms a square base to the whole building. Others of these, however, are simpler in form, and present considerable resemblance to the Scottish borgh; though they appear, when perfect, to have been covered over with a stone dome, or arched roof, and are considered to have been sepulchral monuments, like the more ancient catacombs and pyramids of Egypt.

#### Round Towers.

While the vitrified forts have formed the favourite subject of controversy during the greater part of half a century to the archaeologists of Scotland, the round towers have proved a still more fertile theme for the antiquarian controversialists of Ireland. The most extravagant theories were suggested to account for these singular erections. Phenician, Indian, Danish, and Celtic analogies were all brought to bear on the subject, often with very little judgment or observation. The laborious and intelligent observations of Dr Petrie, the eminent Irish archaeologist, have at length put all these extravagant fancies to flight. Instead of theorising on the subject, he personally investigated these remarkable structures, and arrived at the conclusion that they are ecclesiastical edifices, ranging in date from the introduction of Christianity into Ireland down to about the tenth century. They are believed (by Dr Petrie and his adherents) to have been designed not only for bellfries and watch-towers, but for monastic treasure-houses and strongholds, adapted for places of refuge, whither the clergy could retreat with their most valuable effects when threatened with danger from the assaults of barbarian spoilers.

While these remarkable edifices abound in Ireland, only two examples of them are found in Scotland, and

they are altogether unknown in England. One of the Scottish examples, however—that of Brechin—is a remarkably fine specimen of the later and more adorned style, with the exception of the spire with which it is surmounted, which is obviously an addition of a later age. The other Scottish example is at Abernethy. A comparison of these structures with other ecclesiastical remains in Scotland, independent of written records, affords the most satisfactory confirmation of Dr Petrie's speculations, leading to the conclusion that they are the work of the Dalriadic Scots; a race which emigrated from the north of Ireland in the beginning of the sixth century, and established themselves in Argyleshire, to which they gave the name of Dalriada, it is said, from their leader Riada or Reuda. Within this narrow district the Scots remained confined for upwards of three hundred years, until, in the ninth century, they effected alliances with the northern Picts, and with the assistance of Irish allies, recovered their own kingdom from a Pictish intruder, and at length extended their influence over the whole of North Britain, including the districts where these memorials of Irish architectural skill still remain.

These proceedings, however, as well as the interesting memorials of them to which we have referred, belong to a much later period than that of the Celtic tumulus, or hill fort, or of the ancient weapons and implements which recent researches in connection with them have brought to light.

#### Celtic Weapons and Implements.

The investigation of the contents of Celtic tumuli has furnished the most valuable amount and variety of information which the archaeologist possesses, wherewith to arrive at some degree of knowledge of the habits and degrees of civilisation of their constructors. The contents of these ancient sepulchral monuments, amid all their minute varieties, clearly indicate three distinct stages of society. The first was before the introduction of metals, when arms and implements consisted solely of spear and arrow-heads of flint or bone, and of hammers of stone, and when pierced shells, stones, and beads made of horn or bone, formed the chief personal ornaments. The long barrow, formed like a gigantic grave, appears, from its most common contents, to be the sepulchral memorial belonging to this era, to which archaeologists concur in giving the name of the **STONE PERIOD**—that is, the period when stone and flint formed the only known materials with which to construct the rude weapons and implements required in the operations of agriculture, in war, or the chase. The pit-dwelling may in like manner be assigned as the residence of the same period; and it is extremely doubtful if even the rudest specimens of pottery found in Celtic tumuli must not be regarded as indicative of a period later than that when the unadorned savage found in his shallow earth-pit, roofed in with boughs and turf, a sufficient home and shelter for himself and his family.

A similar state of savage life exists in our own day on the islands of the Southern Ocean. In the absence of all knowledge of the use of metals, the Tahitians, the New Zealanders, and other natives of these islands, are found to construct flint spear-heads, stone adzes and hammers, and the like weapons and implements, so exactly resembling those found in British barrows of the Celtic Period, that it is frequently difficult to distinguish the one from the other. In like manner the red Indians of America were wont to furnish themselves with weapons of flint; while the horn and bone arrows of the modern Esquimaux no less nearly resemble similar relics found in early Celtic barrows. The tasteful carving of the New Zealander's club and paddle are the first evidences of dawning civilisation, showing a desire in the savage mind for something more than the mere supply of his natural wants, and the gratification of his animal passions. Similar evidences of the dawn of taste furnish us with the first tokens of progress in the early Celts.

The use of the sepulchral urn must be regarded as in itself a proof of some degree of progress. The earliest of these, however, are of the rudest possible description. They are fashioned with the hand, of coarse clay, by workmen ignorant of the turning-lathe or wheel of the potter. They are generally extremely unsymmetrical, merely dried in the sun, without any attempt at design, and devoid of ornament. Of a later period, though still accompanied only with weapons and implements of stone, the urn is found neatly fashioned into various forms, and ornamented with different patterns of lines, traced by some instrument in the soft clay, after which the vessel has been baked with fire. The great number of these urns that have been found, and the abundance of the stone and flint weapons scattered over the whole British Islands, and indeed over most parts of Europe, furnish evidence of the same rude tribes having continued with little change to occupy Europe during many generations. A change, however, of a most decided character broke in at length on the barbarous habits of this primitive British race, not improbably by the irruption of more civilised tribes from the East.

#### II. THE BRONZE PERIOD.

The change by which we detect the close of the long era of barbarism in Europe, and the introduction of a new and more advanced period, is the discovery of the art of smelting ores, and the consequent substitution of metallic implements and weapons for those of stone. The first metal worked in Britain undoubtedly was tin, and this may have occurred even before the close of the Stone Period. The early knowledge of this metal is readily accounted for by the abundance of the ore in Cornwall, where it frequently occurs near the surface, and is easily reduced by charcoal and a moderate degree of heat to the state of metal. The history of the trade in tin commences with the very earliest records of commercial intercourse with Britain. The Phœnicians at a remote period visited the British coasts to procure lead, tin, and furs, in exchange for earthenware and instruments of copper. This was unquestionably many ages before the Roman invasion. Long before that period the Greeks had conferred on Cornwall and the neighbouring isles of Scilly the name of the Cassiterides, or Tin Islands, and frequent recent discoveries of Greek coins and other relics have furnished additional evidence of the intercourse which that ancient civilised nation kept up with our island. One of the most remarkable of these relics of remote foreign intercourse with Britain is a bifrontal bust of the Egyptian Isis, covered with hieroglyphics, which was found in the course of some excavations in South Street, Exeter, so recently as 1833. Some Greek coins dug up in the same neighbourhood are mostly of dates fully three centuries before the Christian era.

Notwithstanding the early intercourse thus enjoyed with some of the most civilised nations of antiquity, the influence was altogether local and temporary. The isolated nature of the locality where the veins of tin and copper abound, secluded the early natives of Cornwall from necessarily coming much in contact with the inhabitants of other parts of the island; and as the exchange which they received from foreign traders must have far surpassed in value anything they could hope to gain by bartering with the other British tribes, it is extremely probable that the knowledge and use of metals may have long remained confined to that peninsula. Certain it is, that among all the varieties of ornaments and utensils discovered in ancient British barrows, no instance is recorded in which any article wrought in tin has occurred.

From the few and slight notices of early writers, we learn that bronze was among the articles imported by the Phœnician traders, and given in exchange for the tin which they procured in Cornwall. Evidence, however, is not wanting to prove that both in Britain and along the north of Europe the weapons of the Bronze Period were manufactured by native tribes. In France,

Denmark, Norway, and in the British Isles, moulds made both of stone and metal have been found, exactly corresponding with the bronze axe-heads called *celts*, and with the adzes, spear-heads, daggers, and other weapons found in the barrows of the Second Period. While some of the moulds are wrought with great delicacy, others are so rude as to convey the idea to us that their possessors fashioned their own moulds and cast their weapons much in the same way that a modern sportsman supplies himself with leaden bullets.

The writings of Sir Walter Scott have sufficed to add a fictitious interest to more than one curious tradition of elder times; and in no case is this more noticeable than in the use he has made in the pages of 'Kenilworth' of the curious relic of Scandinavian mythology preserved for so many ages in the popular tradition of Wayland Smith. Although the legendary tales of the wise Smith have so long held a place among the traditions of Berkshire, and the ancient cromlech in the neighbourhood of Farringdon has for centuries borne the name of Wayland Smith's cave, these tales are no less common throughout all the branches of the Teutonic race. The story of Wayland is related at length in the 'Edda,' an ancient Scandinavian poem, embodying the wild and sublime conceptions of northern mythology, and forming the original sacred writings of the Norsemen. It occurs also in the earliest Icelandic sacred poems, and is frequently referred to in the great German epic poem, the 'Nibelungen-Lied.' In all these, different versions are given of the same story preserved by the Greek poets, and evidently a mythic record of the first introduction of the art of working in metals among the northern races.

This Teutonic myth may be unhesitatingly regarded as the traditional memorial of the advent of the Bronze Period among the northern races of Europe. We see in it the hero-worship of the rude Norsemen deifying their Scandinavian Vulcan when he had passed away to the rewards of the Valhalla of their wild creed, and testifying their estimate of the gift he had bestowed on them by according to him divine honours. The remote antiquity to which the wild legends of the Norsemen are referrible, show in some degree the very early period in which this great change must have taken place. In the writings of Alfred the Great a curious allusion occurs which may help to confirm this. Reflecting on the uncertainty and fleeting nature of all worldly fame and honours, the royal poet exclaims—

'Who knows where the bones lie  
Of the wise Weland?  
Under what mound or barrow  
Are they now concealed?'

From this it is obvious that even in the early times of the great Saxon, the story of the old metallurgist had become an ancient and uncertain legend.

The opportunities afforded by the more extended study of archaeology for comparing the indigenous antiquities of the various countries of Europe, enable us more distinctly to demonstrate the extreme state of barbarism in which the aborigines of the Stone Period must have lived, and the immense changes effected on this by the introduction of the art of working in metals. It has been previously observed that the sepulchral monuments of the First Period, with their accompanying weapons and implements, are not peculiar to Britain, nor, indeed, are they at all so common in England as on many parts of the continent of Europe. They are of frequent occurrence on the coasts of the Baltic, and along the shores of the German Ocean. They are found in Holland, Brittany, and Portugal, and on the islands and the coasts of the mainland bordering on the Mediterranean Sea; but they are scarcely ever discovered far inland, unless in the vicinity of some large river or lake. They are, in fact, the monuments of a rude and thinly-scattered people, who subsisted by hunting and fishing, and whose imperfect implements totally incapacitated them from penetrating into the interior of these countries, encumbered as they then were by vast

forests and morasses, which bade defiance to their imperfect implements and simple arts.

The records of the infancy of many great nations preserve some mythic or traditional allusion to the great change effected on the condition of man by the introduction of the metals. In the Sacred History we learn of the sons of Adah—Jabal, 'the father of such as dwell in tents, and have cattle,' and his brother Jubal, 'of such as handle the harp and organ'—the fathers, in fact, of a pastoral life, with its peaceful but unprogressive virtues, such as may still be witnessed among the nomadic tribes of Asia. But her sister Zillah bore Tubalcain, the Vulcan or Wayland of the Mosaic records, 'an instructor of every artificer in brass and iron.' A curious custom among the ancient Egyptians preserves to us in like manner evidence of that people having passed through the same great change in the early stages of their civilisation. In preparing the mummies of the deceased for sepulture, the embalmers proceeded to extract the brain through the nostrils by means of a bronze or iron probe; but it was not permitted to use any instrument of metal in opening the body. The incision in the side, through which the intestines were extracted, could only be made with a sharp Ethiopian stone; and when they had been cleansed and replaced, the eye of Osiris, the Judge of the Dead, was placed as a mysterious seal over the sacred incision. The stone knives of the embalmers have frequently been found in the catacombs. They seem to indicate that some process of embalming had been in use among that ancient people before the introduction of metals, and that (with a feeling easily understood), while the bronze or iron knife was adopted for all common uses, the more ancient implement was retained unchanged for making the sacred incision in the dead.

Milton in like manner refers to the introduction of the art of working in metals in the eleventh book of the 'Paradise Lost,' when the Archangel Michael shows to Adam the future history of his progeny. The new art is there also introduced as the great source of transition from the pastoral state; and the picture the poet presents to the mind singularly realises to us the idea, already referred to, of our own rude ancestors smelting their ores, and each casting his weapons and implements as best he might:—

'In other part stood one who, at the forge  
Labouring, two massy clods of iron and brass  
Had melted (whether found where casual fire  
Had wasted woods on mountain or in vale,  
Down to the veins of earth; thence glowing hot  
To some cave's mouth; or whether washed by stream  
From under ground); the liquid ore he drained  
Into fit moulds prepared; from which he formed  
First his own tools, then what might else be wrought,  
Fusil, or graven in metal.'

No wonder that the wild Norseman elevated to the rank of a Divinity the introducer of the metals to his race. The changes effected by the greatest of modern inventions—by the mariner's compass, the steam-engine, the railway, or even by the printing-press—are not more remarkable than those first produced by the introduction of the metals. It seems probable that we owe to the Teutonic races—among whom we find the legends of Wayland the wise Smith so widely diffused—the introduction of this invaluable means of civilisation among the older Celts. Evidences are not wanting to suggest the inference, that we owe to a far earlier invasion than those of the Belge, the Danes, or the Saxons, the introduction of the metallurgic arts into the British Isles. What particularly marks this change with the characteristics of invasion by a superior race, is the absence of marks of transition. Had the original Celts gradually learned to supersede their rude weapons of stone and flint by the more efficient ones of bronze, we might expect to find the latter in the same class of barrows, and even deposited together under the same tumulus. Such, however, is not the case. The *long barrow* is destitute of relics of the Bronze

Period; and while it is notorious that there is nothing on which changes are more slowly effected among nations than their sepulchral rites and memorials, we look in vain in the new implements of metal for any cause to account for the change in the forms of the tumuli. The conclusion may therefore be regarded as a legitimate one, that they also are characteristic distinctions, marking customs introduced by a new race.

We may picture to ourselves the ancient Celts disturbed by the invasion of tribes armed with weapons scarcely less novel to them than those with which the Spanish discoverers astonished the natives of the New World. Once more they forsook the Eastern shores, and moved towards the north-west, while the forests rang with the woodman's axe, the quarry was wrought for building materials, and the high lands were crowned with the ancient dun, or hill fort, the refuge of a warlike, yet pastoral and partially-civilised people, who had learned to combine for mutual safety and the community of interests which civilisation gives rise to.

*Cromlechs, Standing-Stones, Temples, &c.*

A cromlech consists of several large upright stones, almost invariably without the slightest marks of artificial shaping, over which another large unhewn stone is laid so as to form a kind of rude chamber, as in the following illustration. Occasionally they are found

enclosed by a circle of stones, thereby further assimilating them to the larger Druidical remains, such as Stonehenge. Various theories have been advanced as to the purposes for which they were constructed; the most generally received of which represented them as Druidical altars, designed, as some conceived, for human sacrifice. Careful investigation, however, has sufficed in this, as in most other cases, to show of how little value the mere theorist's labours generally are. Whenever excavations have been made in their centre, they have been found to cover remains which clearly point to their use as sepulchral memorials. Some have been found to contain calcined bones, others entire human skeletons, while both sepulchral urns, and weapons and personal ornaments, have been frequently discovered among their contents. A curious disclosure of one was made during the construction of the Phoenix Park at Dublin in the year 1838. An ancient tumulus, which measured 120 feet in circumference, and about 15 feet in perpendicular height, was ordered to be levelled. During the progress of the work, four *kistvaens*, or coffins formed of separate slabs of stone, each containing an urn of baked clay, filled with calcined bones, were discovered. One of these, which was preserved in a nearly perfect state, is now in the Museum of the Royal Irish Academy. It is gracefully and regularly formed, and neatly decorated with a variety of zig-zag ornaments. In the centre of the mound a cromlech was disclosed, the large covering-stone of which measures 6½ feet in length. Within this were found two perfect male skeletons, and the remains of another. Underneath each of the skulls a quantity of small shells were found, rudely pierced, and strung together with vegetable fibre, so as to form necklaces; and beside them lay a *fibula*, or brooch of bone, and a weapon made of flint. From this, then, it is obvious that the cromlechs must no longer be regarded as altars for barbarous and bloody sacrifices; but as sepulchral monuments, furnishing evidence to us of a patriarchal government, and of the reverential honours paid by the builders to their chiefs. The labour of constructing such a monument, by a people furnished with such imperfect implements, must have exceeded that which

was expended on some of the vast sepulchral memorials of the civilised Egyptians.

Cromlechs are found scattered over the same countries of Europe to which we have already referred as still possessing the sepulchral mounds of this ancient race of builders. Many of them are of far larger proportions than that discovered in the Phoenix Park. Wayland Smith's Cave in Berkshire is a work of this class, and so also is Kit's Coty House in Kent. It has been attempted to establish that the latter is the monument of Catigern, the British commander who fell in the same battle in which the Saxon invader Horsa was slain, A.D. 455; but the marked character of this ancient monument evidently proves it to belong to a much earlier period in our island history.

Scattered over the British Islands, and many parts of the continent, are *standing-stones*, as they are termed—rude blocks of stone placed upright, and evidently designed as commemorative of some remarkable event, the scene of a great victory, or the spot where a mighty chief fell. Others, of a later character, are hewn into regular forms, and decorated with a variety of sculptures. Still later, we find them bearing inscriptions—some in characters still undeciphered, some in the Icelandic and Saxon Runes (a written character, which the Norsemen are thought to have derived in part from the Phœnicians), and some in the Byzantine character, and generally decorated with the cross, the universal emblem of the changes affecting the Christian period to which they belong. Numerous stones of the same class are also found in Scotland, Ireland, Denmark, and other northern countries of Europe, sculptured with snakes, dragons, and the like figures, generally interlaced so as to form a variety of beautiful patterns. Others are covered with figures on horse and foot, and occasionally with symbolic representations, among which the elephant and other devices evidently derived from the East, furnish an additional argument in favour of the Asiatic origin of the early northern races.

The most ancient, and probably the largest, Celtic or Druidical temple of ancient times was at Avebury in Wiltshire; but unfortunately a village has been planted on its site, and only a few slight remains now attest the rude magnificence of its perfect state. It was carefully surveyed by Dr Stukely in 1720. No fewer than 650 blocks of stone were included in the circles and avenues of this vast temple, varying from 5 to 20 feet above the ground, and from 3 to 12 feet in breadth and thickness. The singular structure formed by these huge standing-stones was enclosed by a deep ditch and a lofty bank of earth, of which considerable remains may still be traced. It enclosed an area somewhat exceeding twenty-eight acres. The stones of Avebury were entirely unhewn, and must have been brought together with much labour, frequently from a great distance. On the surface of the ground, both in the neighbouring valleys and on the high lands, larger masses of stone are frequently met with; and there are still a considerable number of detached oolitic sandstones of various sizes lying scattered about at no great distance from Avebury. These are known by the name of Gray Wethers, and from among such the builders of the great Celtic temple selected the materials with which it was constructed. Stukely remarks that Avebury might be regarded as the grand national cathedral, while the smaller circles, which are met with in various parts of the island, may be compared to the parish or village churches.

The vast Druidical temple of Stonehenge (see following fig.), on Salisbury Plain, has attracted more attention than any other relic of antiquity in Britain. It differs from that of Avebury, as well as from all the Celtic monuments of the same class, in being constructed of hewn stones, and manifesting ideas of proportion and regular symmetry of which no other known structure of the kind exhibits any indications. Many of the columns have been squared or hewn by art, and the horizontal stones which surmount the outer circle have been attached to them by mortices fitting the tensions

which have been laboriously cut on them. Readers who have not had an opportunity of inspecting this wonderful monument of antiquity, must not assume, from the above statements, that the huge monolithic

pillars of this temple of Stonehenge are characterised by great symmetry and uniform regularity of proportion. This is not the case. They have only been rudely reduced to the necessary form, but still sufficiently so to characterise them with a most striking and important feature of difference from all other known monuments of the same class, though we may be allowed to smile at the learned essay compiled by Inigo Jones, in obedience to the commands of King James, in which the great architect undertakes to prove that Stonehenge was a Roman temple of the Tuscan order, dedicated to *Cœlus*!

The origin of this singular structure has been the subject of endless speculations for centuries. The earliest-published notice of it occurs in the writings of Nennius, who lived in the ninth century. According to him, 460 British nobles, who had assembled on the spot to be present at a conference between King Vortigern and Hengist, were murdered there; and the Britons afterwards erected the circles of Stonehenge to mark the scene where so many of their chiefs had perished. This would place its erection later than the fifth century, and is altogether untenable. The 'Triads of the Welsh Bards' couple with King Vortigern the more famous Merlin; and this is further enlarged upon by Geoffrey of Monmouth, who wrote in the twelfth century. According to him, the stones were originally brought from Africa, and dropped at Kildare in Ireland, and from thence Merlin removed them by supernatural agency, and placed them upright on Salisbury Plain! By more recent writers all manner of vain theories have been propounded to account for the origin of this ancient British temple. It has been assigned to Phœnicians, Indians, Belgic and British Druids, Romans, and Saxons. This at least is obvious to the archaeologist, that it belongs to a later period than the Great Temple of Avebury. Its hewn stones prove it to be the work of a period when the knowledge of metals had afforded the ancient Britons the means of effecting this. It is not, therefore, a work of the Stone Period—it is probably not even a work of the Bronze Period—but belongs to that later era when the art of smelting the iron ore had given to the northern races of Europe the command of weapons and implements adapted to their untiring energy and patient vigour. It is not improbable that the circle of unhewn stones which forms part of Stonehenge, may have been a lesser temple contemporary with that of Avebury; and that the great circle, and the other gigantic symmetrical features of the temple, were the work of a later age, and of a more advanced state of civilisation.

Personal Ornaments.

Many of the bronze weapons found in early tumuli are exceedingly elegant and graceful in form. The larger spear-heads are frequently decorated with open

loops and borders on the flanges; and the bronze swords, generally known as the leaf-shaped swords, are remarkable for their beautiful proportions. In this country the blade alone is usually found, the handle having apparently been made of horn or some other decaying substance. But in Denmark the leaf-shaped sword frequently occurs with a beautifully-decorated handle of bronze. But it is to the personal ornaments of the same period that we must look for evidences of the greatest taste and skill. Many of these are of pure gold, and finished with much care. In Ireland more especially, beautiful gold brooches have frequently been found of large size, and decorated with amber and fine stones. Torques, or twisted collars for the neck, armille, or large bracelets, and rings of various forms, designed to be worn about the head, the neck, the arms, the wrists, the ankles, and even the waist, have all been found made of pure gold, of silver, and of bronze, and frequently characterised by great beauty of form and decorations. Besides these, bodkins, hair-pins, tweezers, and various other articles, occur among the metal relics of the period, while the contents of the same tumuli frequently include glass and amber beads, and arm-rings and necklaces made of coal and jet. The ornaments on all these furnish evidence of great skill and ingenuity, and prove their constructors to have made considerable progress in the arts of civilisation.

Perhaps the most remarkable of the personal ornaments of the Bronze Period is the torque, or twisted collar worn round the neck.

(See annexed illustration.)

It may be regarded as the most characteristic relic of advanced Celtic art; and, like the race to whom its construction is traceable, it is decidedly of Eastern origin. The gold collar which Pharaoh put round Joseph's neck, is rendered in the Septuagint by the word *strepton* (turned or twisted), and is supposed by some to have been a torque. The same species of personal adornment is of frequent occurrence on Persian monuments, and always under circumstances which imply its having been regarded as a mark of distinguished honour. It is particularly referred to in Kerr Porter's travels, as represented on the staircase of Persepolis, and forming one of the most prominent gifts offered to Darius. It was familiar to the Romans, but only as one of the barbaric spoils that adorned the procession of a triumphant general, or marked the foreign captive that he dragged in his reluctant train. It was recognised by the Romans as a distinguishing badge of the Gauls, and, as such, is introduced in 'that masterpiece of Otesilaus,' *The Dying Gladiator*, which Byron has inspired with such new and touching life in his poem of 'Childe Harold.'

III. THE IRON PERIOD.

The changes effected by the introduction of iron, to those already familiar with the use of copper and bronze, though considerable, would be slight and unimportant when compared with the radical improvements effected by the first discovery of metals. The evidence from which we may trace the first introduction of the commonest and most useful of all the metals to the races of northern Europe, is necessarily much more imperfect than that from which the previous conclusions have been deduced in relation to the Stone and Bronze Periods, owing to the rapid destruction of iron, unless under the most favourable circumstances. Nevertheless, we are possessed of abundant evidence to show that iron was in use among the races of northern Europe long before the Roman legions had subjected the Gauls and Britons to the imperial sway. The term, therefore, of the *Iron Period*, or *Iron Age*, very fitly suffices to designate the last period of heathenism, prior to the subversion of native arts and habits by the superior

proress of Rome, and the influence of her more advanced civilisation and refinement.

The Museum of the Royal Academy at Dublin contains a valuable collection of iron swords, axes, and spear-heads, found at Dunshaughlin. They undoubtedly belong to a very early period, and their fine state of preservation is ascribed to the immense quantity of bones which surrounded them, the decomposition of which, by forming a phosphate of lime, prevented the rapid corrosion of the metal. Another beautiful collection of ancient iron weapons, believed to be Danish, was dug up near Island-Bridge during the construction of the Dublin and Cashel Railway. The mountings of the swords were mostly of brass, but a few of them were richly plated with silver, and one is said to have had a hilt of solid gold. In the celebrated museum of the Northern Antiquaries at Copenhagen, ancient iron swords and other hand weapons are preserved, some of which have the hilts ornamented, and partially inlaid with silver.

Numerous relics of various kinds might be added to those already described, belonging both to the periods of bronze and iron. The above, however, will suffice to characterise these periods, and to show with considerable vividness the degree of civilisation to which the inhabitants of northern Europe had attained before the irruption of the Roman legions into the countries within which these races had been securely established for many ages.

ROMAN ARCHÆOLOGY.

In treating of the relics which preserve to us the evidences of Roman arts and civilisation, the archæologist finds himself in an altogether new and clearer region. Here literature furnishes a safe and unerring guide. Inscriptions, names, and dates, fix the exact era to which each temple or palace belongs; or, with even minuter accuracy of detail, furnish the names of the cohorts of the Roman legions, and of the officers who led them into the various districts of each country which successive conquerors selected as the field of victory. Nevertheless, the archæologist is able to add much to the previous narratives of the historian, by his interpretation of the relics which are from time to time brought to light. The revelations of Pompeii and Herculaneum have given an insight into the domestic habits and social life of the ancient Roman, such as no study of classic literature could furnish. The study of Roman antiquities, however, is still more interesting and instructive when it forms a portion of the early history of the nations subjected to imperial sway.

ROMANO-BRITISH PERIOD.

The investigation of the antiquities of the Romano-British Period forms a most important branch of inquiry in searching into the early history of Britain. By this means we are able to trace the first introduction of many of the arts which superseded the ruder devices of the ancient Britons, and still minister to our social comforts and personal enjoyments. To the Romans we probably owe the first manufacture of bricks and tiles, and the great step in advance of the rude habits of a people scattered amid the forests of a thinly-peopled country, consequent on their gathering into large communities, and building substantial dwellings, a imitation of their conquerors. Luxury, tempered by the disciplined hardiness of soldiers, soon created new wants, and incited many dormant faculties into action. The Roman mansion, with its baths, its fires and stoves, its mosaic paving and painted walls, its sculptures, bronzes, and furnishings, all opened up new sources of wonder and of knowledge to the intelligent barbarians who had in vain withstood the legions of Cesar. The ancient British pottery is found to have altogether disappeared on the introduction of Roman arts. The rudest fictile vessels of the Romano-British period may be distinguished at a glance from those of the native period. They are essentially different in form, and much superior in manufacture—the Britons

having learned from their conquerors the art of constructing and efficiently using the potter's kiln.

The forms of Roman weapons and implements, and of every variety of domestic utensil or personal ornament, were no less markedly distinguished from those of the native British. They were not simply superior to them: they were essentially different in form and style, and superseded them as a natural consequence of the substitution of Roman for native rulers. Numerous sepulchral and commemorative inscriptions have been discovered in every part of Britain where the Romans established permanent stations. Inscribed altars are also of frequent occurrence, and all these afford valuable materials for the historian. They furnish unmistakable evidence of the state of the arts at different periods prior to the decline of the Roman Empire, and their final abandonment of Britain. They also suffice to show the nature and extent of the Roman works executed under the various commanders who ruled the destinies of Britain at that important era of its social pupilage.

The Newcastle Museum is exceedingly rich in Roman remains, and particularly in inscribed tablets and altars, owing to its vicinity to the Wall of Hadrian and Septimius Severus. The Hunterian Museum at Glasgow is also enriched with a valuable collection of a similar nature, derived in like manner from its vicinity to the Wall of Antoninus. From both of these collections, curious and minute information has been furnished to the historian, showing what legions occupied the country and constructed the works, which still leave enduring traces of their presence after the lapse of fourteen centuries. Legionary inscriptions have also been found on tiles. At York they have been discovered in great numbers, stamped with the inscriptions of the sixth and ninth legions; and in London, though more rarely, bearing an abbreviated inscription, which is rendered—*The First Cohort of Britain, in London*. It thus appears that the Roman soldier was not only employed in constructing military works, but was engaged in useful manufactures, so that he became the instructor, as well as the conqueror, of the subject Britons.

The miscellaneous remains of the Romano-British Period embrace an immense variety of articles, a mere enumeration of the names of which would answer no useful purpose. London and York have proved peculiarly fertile in the disclosure of such relics of the conquerors of the world, and, more recently, no single locality in England has furnished so interesting a variety as Colchester. In digging a foundation there in the year 1821, for enlarging the public hospital, a singularly-interesting and novel piece of Roman sculpture was discovered. It consists of a sculptured figure of a sphinx, twenty-five inches in height, seated, and holding between its fore-paws the head and other remains of a human being, who has fallen victim to the wiles of this singular creation of classic fable. A considerable quantity of pottery, tiles, and fine-glazed ware were dug out of the same locality. Two fragments of Roman inscriptions were likewise found there, and a small bronze figure of the sphinx. Since then, Roman remains of various kinds have occasionally been turned up, until the present year (1849), when further extensive excavations have led to the discovery of a most valuable collection of pottery, and other relics of Roman art; which have been preserved to form the nucleus of a local museum, devoted chiefly to the antiquities of the county of Essex.

ANGLO-SAXON PERIOD.

The Anglo-Saxons succeeded to the occupation of Britain after its desertion by the Roman legions, on the decay of the Empire; and under them Britain once more underwent new and important changes. In some respects it returned to ancient manners: the classic mythology gave place to the northern deities of the Scandinavian and Teutonic creeds: the arts assumed a new form, in which the elements both of Scandinavian and Roman models are combined. Among the contents of Anglo-Saxon tumuli, glass vessels and

drinking cups frequently occur. Many of these are formed so as not to admit of their being set down unless when empty, and have been thought to furnish a curious illustration of the habits of our Saxon forefathers, among whom the vice of hard drinking is known to have been so common. Pottery, arms, and implements of various descriptions, are all frequently found among the contents of the Anglo-Saxon barrows; but perhaps the most interesting class of relics belonging to this period is the personal ornaments, which include enamelled and jewelled fibulæ, rings, necklaces, crosses, &c. The most characteristic ornament of this period is the *Runic Knot*, a species of interlaced ornament, which continued in use, with slight variations, till the twelfth century, and is frequently found among the decorations on the earliest ecclesiastical edifices belonging to what are commonly styled the Saxon and Norman, or Byzantine, Periods of Architecture.

The introduction of the cross among the personal ornaments of the Saxons points to the remarkable change effected by the introduction of Christianity. The Roman missionary and the Roman monk succeeded to the conquests of the Roman legions, and triumphantly planted the cross where the imperial eagle had only gained a temporary and disputed possession. Thenceforth the influence of the creed and of the ecclesiastical polity of the Christian missionaries manifested itself in every phase of social life, and revolutionised the arts no less than the morals and manners of the Anglo-Saxons. One counteracting influence, however, long continued to hold them in check. The Danish and Norse rovers, who won to themselves the name of the Sea-Kings by the daring hardihood with which they steered across the ocean, and enriched themselves with spoils gathered along the whole northern and western coasts of Europe, made frequent descents on the eastern shores of England and Ireland. Many relics of these barbarous invaders have been met with from time to time, contrasting with the more familiar productions of native art and skill. Several long and straight swords, with hilts altogether differing in form and ornaments from those usually ascribed to the Anglo-Saxons or native Irish, are preserved in the Museum of the Royal Irish Academy, and are regarded by most intelligent antiquaries as relics of these Norse invaders.

#### Ancient Chessmen.

Another and very characteristic class of relics of the Sea-Kings, is the dice and draughtsmen frequently found along with more warlike remains, and serving to illustrate the love of gambling for which these wild Norsemen were notorious. They are exceedingly common in Denmark, and have been frequently found in Ireland, generally consisting of a conical-shaped bone, with a hole in the bottom, designed, as is presumed, for use on shipboard, to beguile the tedium of their long sea-voyages, the hole being intended to fit on to a pin, so as to keep them from slipping with the motion of the vessel. Of the same class, though belonging to a later period, are the ancient chessmen, wrought of the teeth of the walrus. Large sets of these have occasionally been discovered, possessing great value from the illustrations they afford of ancient costume. The frequent occurrence of the bishop among these latter figures, fixes them as belonging to a period subsequent to the introduction of Christianity. In the year 1831 a number of these ancient chessmen, beautifully carved with a rich variety of ornaments, were discovered in the island of Lewis, buried fifteen feet under a bank of sand. They were purchased by the trustees of the British Museum, and now form a part of that valuable national collection. In the 'Guide to Northern Archaeology,' published by the Society of Northern Antiquaries of Copenhagen, woodcuts are given of specimens of sets of ancient chessmen found in Denmark; exactly similar in character to those so recently discovered in the islands of Scotland.

The arts, the arms and implements, and the architecture of the mediæval Christian era, all come within

the province of the archaeologist; but they demand a much larger space for their consideration than a popular sketch of the science can possibly include. (See Nos. 28 and 58.) One class of antiquities, though not the most pleasing, may be selected from these, as peculiarly illustrative of the manners and the degree of civilisation of the period—that is, the

#### Engines of Torture, &c.

The use of torture as a means of obtaining judicial evidence cannot be regarded as a creation of the Middle Ages, seeing that it was in use both among the Greeks and Romans. Torture was used, according to the Athenian laws, in eliciting evidence from slaves, and is affirmed by Cicero to have been legally applicable to Athenian citizens. It is doubtful if it was used by the Romans during the period of the Republic, but it had come fully into use in the time of the early emperors, and was subjected to scarcely any other restraint than the will of the despotic rulers of Rome during the later era of the Empire. Among the northern nations, however, whose manners and early civilisation have been traced through the remote eras to which archaeologists give the names of the Stone, Bronze, and Iron Periods, the use of torture in judicial proceedings appears to have been unknown. This cannot be ascribed to any superiority of the northern races in refinement or humanity when compared with the polished Greeks and Romans. The barbarous cruelties of the Sea-Kings especially are only to be equalled by the proceedings of the savages of Polynesia or North America. But among the whole northern races, the Teutonic and feudal appeal to ordeal or battle, appear to have existed under some modified form, from the earliest times, as judicial tests, which were rendered infallible by their supernatural character. So long as this *judicia Dei*, or judgment of God, as it was termed, continued in use, we have no evidence of torture being resorted to; and among the Germans more especially, where the Teutonic customs and influences were most strongly rooted, judicial torture appears to have been unknown till the close of the fourteenth century.

The engines employed in the infliction of torture have been as various as the inventive ingenuity of man is fertile in device. The monks, under the influence of a misdirected zeal for the attainment of a holy life, and securing a claim to heaven by their own good works, devised penances, mortifications, and austerities, which were directed only against themselves. In the thirteenth century we find the first traces of the use of torture for inquisition of heresy introduced into ecclesiastical law. While the Church exercised so beneficial an influence in softening the barbarism of the northern races, and ameliorating the condition of the people under the lawless tyranny of the feudal system, she appears as the introducer of this barbarous practice at a period when civil institutions and equal laws were rapidly displacing the ruder customs of feudal supremacy. In the great struggle between the Pope—Clement V.—and the Templars in 1310, inquisitors were appointed to examine the knights charged with heresy. The Archbishop of York, one of the inquisitors, hesitated to make use of torture in the investigation; and in consequence of his doubts, Edward II. refused to permit its application to the accused. On learning of this interference, Clement wrote a letter of remonstrance to the king; and after considerable hesitation he submitted, by advice of his council, and a precept was issued to the sheriffs of London, who had the accused in charge, to suffer the inquisitors to examine them by torture. From this it is obvious that until the fourteenth century torture was unknown in England, either as a royal prerogative or an instrument of judicial inquiry. Edward II., the wretched king who thus first sanctioned the use of this terrible engine of inquisition in England, himself perished by torture in 1327, by the hands of two ruffians to whom his own queen, Isabella, the 'She-Wolf of France,' had consigned him for that purpose.

## ARCHÆOLOGY.

The iron cage was an instrument of torture in frequent use by the cruel and superstitious Louis XI. of France. In this the wretched captive could neither stand up nor lie down at full length, and yet some of the victims of the tyrant survived for years in this horrid durance. Somewhat analogous to this were the irons frequently used by ecclesiastical inquisitors, and which formed part of the missionary furniture of the Spanish Armada, by means of which the sufferer was bound with his neck, arms, and knees drawn together. It is a curious fact that this same dreadful posture of enforced constraint was resorted to by the pilgrim fathers of New England as the readiest mode of judicial punishment. The award to the earliest culprits of that settlement is to be bound neck and heels together, and to be left in that state without any food for twenty-four hours. The culprits had been convicted of fighting a duel, and the verdict was put in force; but their sufferings were so great, that they were released after having borne only a portion of their appointed punishment.

The rack was the commonest engine of torture throughout Europe, both in ecclesiastical and civil investigations. It is said to have been introduced into the Tower of London by the Duke of Exeter in the reign of Henry VI., and thence obtained the name of the Duke of Exeter's daughter. This device was improved upon for its horrible purpose in the reign of Henry VIII., by Sir William Skevington, lieutenant of the Tower; and it is by a popular corruption of his name that the most dreadful engine of this kind ever used in England obtained its familiar title of the Scavenger's Daughter. It was discovered by a committee of the House of Commons, who had been appointed in the year 1604 to investigate some parts of the Tower, and especially the ancient dungeon of torture called 'Little Ease.' Besides the rack, a variety of instruments of torture were used in England, such as the gag, thumbscrews, pincers, manacles, fetters, &c.; to which list may be added the mutilations and the pillory of the Star Chamber and High Commission Court of the Stuarts.

Both in English and Scottish history many examples occur of the use of torture, as a barbarous means of revenge either on a captive enemy or a great criminal; and some relics of this are still found in the punishment which the English law awards to the crime of high treason. In 1438 the murderers of James I. of Scotland were put to death at the Cross of Edinburgh with the cruellest tortures that the ingenuity of a barbarous age could devise. The Earl of Athol, after having his flesh lacerated with pincers, and torn with heated irons, was elevated on a high pillar in sight of the people, and crowned in derision as the king of traitors with a red-hot iron crown. The use of torture in judicial investigations was continued in Scotland long after it had been abandoned in England; and James II. acquired peculiar infamy for the use he made of this dreadful means of oppression against the Scottish Presbyterians during his government of Scotland under Charles II. The instruments chiefly employed for this purpose were the 'boots'—which consisted of an iron case drawn over the leg, between which and the flesh wedges were driven in with a hammer—and the thumbkinds, which were applied to the thumbs, and tightened by screws, sometimes till the bones were crushed under the merciless infliction.

Along with the relics of a barbarous age just described, the instruments anciently in use for capital punishment may be classed. The guillotine, which has acquired for its improver—Joseph Ignace Guillotin, a physician of France—an unenviable celebrity, was in use long before, under other names, in Germany, Bohemia, Italy, England, and Scotland. In Germany it bore the characteristic name of *Falbidel*, or the Falling Hatchet; in Scotland it was known by the singular title of the *Maiden*. Tradition assigns the introduction of this instrument into Scotland to the Regent Morton, who was one of its early victims; but it is proved to have been in use some time before his regency. The origi-

nal instrument of capital punishment, by which many of the most eminent men in Scotland were beheaded, is still preserved in the Museum of the Society of Antiquaries of Scotland, at Edinburgh. It consists of two upright beams, with a groove in each, between which an iron axe, loaded with lead, is moved up and down by means of a rope passing over a pulley at the top; a third beam projects behind, to which an iron trigger is attached. On this the rope was secured by a loop, and the executioner released it by a stroke of a mallet, and let it fall by its own weight on the neck of the criminal. Halifax in Yorkshire was the only place in England where a similar instrument was ever used; though the scenes of butchery frequently enacted on Tower Hill and elsewhere, through the tremor or inefficiency of the executioner, prove that the guillotine was a merciful improvement on the axe of the headsman. In France, the improved instrument of its ingenious physician still remains in use for the execution of criminals. It would be an excessive refinement of criticism to pronounce it a more barbarous engine of death than the gallows and the halter, though its terrible associations with the victims of the Reign of Terror might furnish a very sufficient reason for its disuse in the most polished nation of modern Europe.

### AMERICAN ANTIQUITIES.

The antiquities of the New World occupy a place in the investigations of the archeologist altogether apart from every other branch of his studies, though the very recent date of the discovery of the great continents of North and South America only renders more interesting whatever is calculated to throw light on their previous history. America has its Stone Period as well as Europe and Asia. Tumuli, the burial mounds of ancient races, are found in many parts of North America, containing spear-heads and adzes of flint and stone, and urns of rudely-baked clay, not greatly dissimilar to those found in the barrows of Wiltshire or in Denmark and Brittany. This, however, can hardly be regarded as furnishing conclusive evidence of early intercourse or a common origin, since it only exhibits the relics of that primitive stage of society through which the most civilised nations of antiquity appear to have passed. The Society of Northern Antiquaries of Copenhagen published in 1837 a work of great learning and research, entitled '*Antiquitates Americanae*,' designed to furnish evidence of the discovery of the American continent by the Norsemen several centuries before the voyages of Columbus. In one of the communications furnished to the antiquaries of Copenhagen by the secretary of the Rhode-Island Historical Society, it is remarked:—'In the western parts of our country may still be seen numerous and extensive mounds, similar to the tumuli met with in Scandinavia, Tartary, and Russia; also the remains of fortifications that must have required for their construction a degree of industry, labour, and skill, as well as an advancement in the arts, that never characterised any of the Indian tribes. Various articles of pottery are found in them, with the method of manufacturing which they were entirely unacquainted. But, above all, many rocks inscribed with unknown characters, apparently of very ancient origin, have been discovered, scattered through different parts of the country, such as it was impossible so to engrave without the aid of iron or other hard metallic instruments.' Of several of these rocks engravings are given; and while some are in rude and unknown characters and hieroglyphics, others are unquestionably engraved in Runic characters, corresponding to the ancient monuments of Northern Europe.

It is in the southern parts of the North American continent, however, that the most interesting evidences of ancient manners and the arts of civilisation are to be found. Allusion has already been made to the pyramids of Mexico; but besides these, ruins of great extent and considerable variety of design still attest the magnificence of the ancient kingdom of Montezuma. Many of the older and more important monuments re-

maining in Mexico are regarded as the work of a still earlier race than that which gave way before the fierce soldiers of Cortez—probably of the Toltecs—but the inquiry is still involved in considerable obscurity, and would require to be discussed at considerable length with any hope of further elucidation.

Much new interest has been conferred on the subject of Mexican antiquities by the publication of Stephens's 'Incidents of Travel in Yucatan.' This enterprising traveller, after exploring many new regions of Central America, had his attention drawn to Yucatan by accounts he received of ancient ruins of great extent which lay buried in the vast forests with which nearly the whole of that country is covered. On exploring these his highest expectations were gratified. In the narrative of his travels he gives an account of visits made to forty-four ruined cities, many of them containing extensive remains of temples and palaces still covered with sculptures, and frequently adorned both with paintings and hieroglyphics. Mr Stephens's work possesses a further value from being adorned with numerous engravings of these gigantic memorials of an ancient race—engravings from which we reduce the annexed illustration exhibiting the front and back of a

stone idol found at Copan. In their mode of structure or the details of their decoration, there is nothing which suggests any resemblance to the ancient monuments of any people of the old world. They appear to have been the unsided creations of national genius among the ancient Indian races; and Mr Stephens considers—notwithstanding the degradation to which the Indian natives of Yucatan have been reduced under the domination of their Spanish conquerors and priests—there is no reason to doubt that they are the descendants of the builders of Uxmal and Kabah, though no tradition has survived to connect them with so honourable an ancestry. A very large portion of the country lying between the Bay of Honduras and the Gulf of Mexico still remains unexplored. Considerable parts of Central America, and a great proportion of the southern continent, are equally unknown. Beyond the intricate forests that bound the known regions of Yucatan, or even within their recesses, vaster and far more interesting ruins may lie buried, nor is it at all impossible that Indian cities may still remain in the possession of their native occupants, and temples exist there where the ancient idols of Mexico and Yucatan are still worshipped by races who only know of the existence of the white man by some vague and uncertain tradition, borne to them by a stray wanderer from the regions conquered by the early adventurers of Spain.

It is worthy of notice, that among the sites of the ancient temples and ruined cities of Mexico and Yucatan, tumuli occur of the same character as those which in other places of the world indicate to us the primitive habits of the human race, ere the arts of civilisation have modified this character into the manifold peculiarities of distinct nationalities. During the visit of Mr Stephens and his companions to the village of Chemax, while travelling through Yucatan, the cura informed them that at some leagues distant, nearer the coast, were several mounds or tumuli. The Indians had been employed shortly before in digging and excavating in the neighbourhood of them for stones for building; and on chancing to dig into one of the tumuli, they uncovered three skeletons, all in a state of extreme decay, which, according to the cura, were those of a man, woman, and child. At the heads of the skeletons were two large vases of *terra cotta*, with covers of the same material. In one of these was a large collection of Indian ornaments—beads, stones, and two carved shells. The other vase was filled to the top with arrow-heads, made of obsidian, most probably the work of the ancient Mexicans, in whose country volcanic regions abound. Besides these, Mr Stephens was struck by being shown a penknife found in the same tumulus, and which he regarded with peculiar interest as a memorial of the European discoverers of Yucatan, and an evidence of the probable date of the tumulus. 'Speculation and ingenuity,' says he, 'may assign other causes; but in my opinion the inference is reasonable, if not irresistible, that at the time of the conquest, and afterwards, the Indians were actually living in and occupying those very cities on whose great ruins we now gaze with wonder. A penknife—one of the petty presents distributed by the Spaniards—reached the hands of a cacique, who, far removed from the capital, died in his native town, and was buried with the rites and ceremonies transmitted by his fathers.' The accounts of the Spanish conquerors describe the Indians as opposing them with wooden swords, and the like imperfect and primitive weapons of war. Among them, therefore, the spear and arrow-heads of flint and obsidian are likely to have been in use; but such instruments would be utterly inefficient as tools for sculpturing the temples and palaces of Yucatan; and we must therefore either regard the latter, like those of Mexico, as the works of an older and superior race, or question the inference which derives from the discovery of the knife—evidence of the tumulus being contemporaneous with the era of the Spanish invasion.

In the course of the preceding sketch, the reader can hardly fail to be struck with the uniform characteristics which are found to belong to the human race in the primitive stages of society. In Egypt, on the banks of the Euxine, along the shores of the Mediterranean, and throughout the whole northern regions of Europe, we discover evidences of a primitive state of society, through which the races occupying these different localities have passed to higher states of civilisation. In the new world the same tokens of this rudimentary stage of social life meet us, alike in the forest regions of the Red Indian savage, and in the southern parts of the same great continent, where the Spaniards found cities and temples that gave evidence of high civilisation and considerable progress in the useful and ornamental arts. Modern voyagers have found the natives of the South Sea Islands living in the state of society to which these memorials of extinct races point. By such comparisons, therefore, archaeological studies open up to us a most interesting and instructive chapter in the history of man. They disclose to us an era hitherto almost unknown to the historian; and, enabling us to start from a well-defined stage of life in the infancy of the social state, they lead us, by a satisfactory chain of evidence, to the period when complete and trustworthy historic records render the investigations of the antiquary and the inductions of the archæologist no longer necessary for the discovery of truth.

## RHETORIC AND BELLES LETTRES.

RHETORIC is a branch of knowledge and practice having reference to spoken and written compositions, and to the means of employing language so as to produce its greatest possible effect on the minds of men. While the rules of grammar are intended to secure correctness and uniformity in inflecting words, and in joining together the parts of speech in sentences, according to the established usages of each separate language, Rhetoric considers the meaning and form of the composition, and the total effect upon the persons addressed.

Belles Lettres, or Polite Literature, expresses a class of literary productions whose subjects are the principal matters of human interest occurring in the world, and which are adorned with the utmost elegance and polish of style and treatment. They correspond to what is universally interesting—the conversation of the most cultivated classes of society. The chief works contained under this branch of composition are the productions of the poetic art, together with prose narrations, expositions, and criticisms, in reference to nature and human life; including histories, annals, and biographies; discussions of the doctrines bearing on human welfare; criticisms and judgments of the characters, works, and ways of men, calling forth the attendant emotions of reverence, admiration, esteem, love or hatred, sympathy or antipathy. The greater portion of our periodical literature comes under this head. Such productions are contrasted with works of science; for these are supposed to inform us, once for all, on some branch of nature; whereas works of literature are intended to supply an undying appetite for intellectual and emotional excitement.

The following may be regarded as the leading varieties of address that come within the province of Rhetoric, as above defined:—

1. The simple forms of establishing a common understanding between man and man; the word of command, the phraseology of direction, intreaty, question, answer, acquiescence, refusal, co-operation, resistance, concurrence, opposition, and the like.

2. The communication of thought, information, ideas, and sentiments, or of the more permanent products of intellect which are comprehended under the terms knowledge and science.

3. Persuasion, or the means of inducing men to act as we wish, not by external compulsion, but through their own dispositions and impulses.

4. The productions of poetic and literary art.

5. The giving vent or expression to individual feelings, for the relief or gratification of the inward states of our being.

6. The modes of cultivated address employed in the refined intercourse of life.

Before touching in detail upon these various heads, it may be convenient to discriminate and discuss

### THE ATTRIBUTES OF STYLE IN GENERAL.

The leading attributes of style that are of a Rhetorical kind may be set forth under the following heads; it being assumed that grammatical and idiomatic purity and correctness have been previously secured by the appropriate means:—

#### Simplicity.

By Simplicity we are to understand what is easily comprehended, or what is level to the ordinary capacity of men. It is opposed not so much to the complex as to the *abstruse*; and implies a mode of address that does not require severe effort, or a special training for its comprehension. The possibility of being simple in this sense will of course depend much upon the subject

matter; but we can nevertheless consider, in general, what things are requisite to bring out the quality.

Simplicity is twofold—simplicity of terms, and simplicity of structure.

Terms are simple, in opposition to *abstruse*, on various grounds:—

1. They may be the names of common and familiar objects and actions, instead of such as are rare or remote. 'He that doeth these sayings is like to a man that buildeth his house upon a rock;' in this sentence every one of the terms has the simplicity that attaches to meanings common and familiar. Objects of a *technical* description, or such as come under the notice of only limited classes of people, cannot enter into simple composition.

2. The terms may relate to things that are in their nature palpable and conceivable, rather than obscure or invisible. The world is partly made up of objects of a kind to act upon all our senses, such as the solid masses that support and surround us; and partly of subtle and impalpable agents, like electricity, or the mysterious attractions and repulsions that keep up the activity of the sensible masses. Now, all references to the one class of things is universally intelligible, while allusions to the others are understood only by such as have received the artificial training necessary to grasp them. The common objects of the landscape are simple in this sense: the discussions about gaseous bodies, gravity, elasticity, vitality, and the like, are necessarily *abstruse*.

3. What are called *concrete terms* are, in general, more intelligible than the names of *abstractions*. A concrete object is a thing as it exists in nature, with all its parts and peculiarities—such as a mountain, a river, a metal; while an abstraction is some property of these artificially conceived apart from the rest—such as height, density, velocity, liquidity, lustre, specific gravity. Now the gross object is usually more conceivable by the mind than its separate properties; hence although this abstract mode of viewing things is essential to the thorough comprehension of the world, yet for popular composition the terms of the other class are more suitable. There is, however, the greatest possible difference in the intelligibility of abstractions: while some are within the reach of the least cultivated minds, others, such as the subtlest ideas of mathematics, chemistry, and physiology, presuppose a long course of laborious studies. Height, depth, strength, whiteness, virtue, are popular abstractions; polarity, infinitesimal, ellipsoidal, express notions that can never enter into popular composition.

4. Of abstractions, some are fictitious and untrue to the nature of things, being the premature efforts of men to get at the secrets of nature; while others are sound and valid generalizations, and are therefore likely to coincide better with our experience. In general, the ill-formed abstractions will be the most difficult to comprehend. The epicycle orbits of the planets were less conceivable than the ellipses which are their accurate path. The imaginary element 'phlogiston' gave a far less clear and simple idea than is now possessed of the action of burning. But, on the other hand, shallow explanations of natural phenomena may be more conceivable than the true. Descartes's whirlpools of ether rendered the account of the heavenly bodies more level to the popular understanding than did Newton's centripetal and centrifugal forces.

The progress of accurate thinking necessarily leads to a corresponding improvement in the simple and accurate composition.

*Simplicity of structure* means such an arrangement of terms in clauses, and of clauses in sentences, as renders the meaning comprehensible without severe attention

or special study. When the clauses succeed one another in the exact order in which the ideas can be best apprehended; when what is necessary to complete a meaning is not too long delayed, nor interrupted by other distracting meanings; when only a moderate number of particulars is required to make up one complete statement; and when no circumstances are present to produce complexity, distortion, confusion, or overloading—the structure is likely to be simple. The difficulty of attaining simplicity of structure arises from the nature of the subject: the stream of composition can consist of only one thread, whereas it may be desirable to narrate a complex tissue of events, or to represent a number of things all happening at once, as in historical composition. In such cases the skill and art of the writer are shown by his being able to embody his matter in a series of clauses and sentences where the particulars are arranged without perplexity. Short sentences are necessarily simple; long sentences may be either simple or not. Some writers, such as Addison, Bolingbroke, Johnson, Hall, who use long sentences, construct them nevertheless with great simplicity of arrangement; others, of whom Milton is the most remarkable example, delight in a highly-involved and complex kind of composition.

#### Clearness.

This attribute is opposed to indistinctness, faintness of meaning, vagueness, ambiguity, uncertainty. It implies that the forms and images presented to the view shall be sharp, clear, and unmistakable. It is a merit that cannot belong to the style, if not first possessed by the thought; but it is possible that the clear thoughts of one man may not be clearly conveyed to another man. As already observed on simplicity, clearness depends partly on the terms and partly on the structure. Not only must terms be used that express well-ascertained and certain ideas, but they must be so joined that the result shall indicate only one meaning. Since many words have more than one sense, it belongs to the composition to join them together, so that every interpretation shall be excluded except the one intended. To effect this, in treating difficult subjects, is nearly the hardest task that occurs in composition. In poetry, Homer and Dante are remarkable for the surpassing clearness of their images. In prose exposition, Hobbes is a pre-eminent example.

#### Strength.

Strength, vigour, and force are attributes of style, as well as of every other form of human activity.

This quality must mainly depend upon making choice of such terms as by their sounds, or by the images associated with them, echo the powerful objects and actions of nature or of human life. The effect of employing, as illustrations, the mighty agencies of the thunder, of the ocean, the cataract, the wild beast, and the like, is known to every one.

Strength is likewise produced by the use of language strongly suggestive of the circumstance and detail of actions and events, in place of their weak generalities. Thus, when we speak of killing or taking away life, the effect is very feeble; but when the specific act of violence is alluded to, as 'The men whose daggers stabbed Cæsar!' a far stronger impression is conveyed.

Apart from the choice of terms, the quality of strength is brought out by peculiarities of structure and arrangement. The placing of the forcible word of a sentence in the position of natural emphasis adds to the effect—as 'Great is Diana of the Ephesians.' The figure of interrogation has also a striking effect—'Breathes there a man!' and so forth.

In general, brevity is a feature of strength; it is hardly possible, by a diffuse verbosity, to give an energetic impression, whatever other beauties may be embodied upon that kind of style.

Milton is perhaps the greatest example of the quality of strength that the English language presents; for although Shakspeare produces strokes that could hardly

be surpassed, it is a sustained peculiarity in the writings of the author of 'Paradise Lost.' English literature abounds with energetic compositions: the well-known names of Barrow, Bacon, Dryden, Pope, will present themselves to most readers.

Liveliness, vivacity, animation, express a mode of strength or energy, and depend in the very same manner upon the choice and arrangement of terms.

The most difficult variety of style under this head is what is called soaring or taking a flight, which must be carefully managed, so as to avoid a break, a fall, or, technically—a *balhos*. Our greatest poets and prose writers have furnished successful instances of this quality: it is also a frequent accompaniment of the higher kinds of oratory.

The following passage from Dr Chalmers, on the past eternity, is a good illustration of a lofty flight powerfully sustained:—

'One might figure a futurity that never ceases to flow, and which has no termination; but who can climb his ascending way among the obscurities of that infinite which is behind him? Who can travel in thought along the track of generations gone by, till he has overtaken the eternity which lies in that direction? Who can look across the millions of ages which have elapsed, and from an ulterior post of observation look again to another and another succession of centuries; and at each farther extremity in this series of retrospects, stretch backward his regards on an antiquity as remote and indefinite as ever! Could we by any number of successive strides over these mighty intervals, at length reach the fountain-head of duration, our spirits might be at rest. But to think of duration as having no fountain-head; to think of time with no beginning; to uplift the imagination along the heights of an antiquity which has positively no summit; to soar these upward steeples till, dizzied by the altitude, we can keep no longer on the wing; for the mind to make these repeated flights from one pinnacle to another, and instead of scaling the mysterious elevation, to lie baffled at its foot, or loe itself among the far, the long-withdrawing recesses of that primeval distance, which at length merges away into a fathomless unknown; this is an exercise utterly discomfiting to the puny faculties of man.'

#### Feeling.

This term is used here in a restricted sense, to express the quality of touching the warm feelings, affections, and tenderness of humanity. It involves the use of phrases to suggest genial and homefelt attachments and associations—family, country, friends, and all the force of sentiment that is wound up in the sociability of our nature. There are a certain number of the relationships of life founded upon natural tenderness, and the terms expressing them naturally come to excite a certain glow of this feeling when they are properly used. Child, parent, fatherland, native country, are all terms suggesting tender emotion; and there are an infinity of occurrences in life that involve this class of phrases; and according as they are employed with skill and keeping, in any kind of composition or address, the style is said to possess feeling. The addresses of the pulpit usually aim at this peculiarity, which serves both to gratify the hearers with warm emotion, and to act as a stimulus to a certain course of conduct. The closing words of the twenty-third Psalm are singularly replete with feeling: 'Surely goodness and mercy shall follow me all the days of my life, and I shall dwell in the house of the Lord for ever.'

It necessarily happens that the native terms of the English language, which were formed and fashioned by the native English heart, are more impressive than the phraseology of foreign nations and remote climates, such as the Latin, Greek, and French portion of our language. But the cultivation of our schools and colleges has made foreign idioms, and the associations and history of ancient and distant nations, as full of tenderness and warmth to the educated classes as any of

our native compositions. The effect of this, however, is to constitute two different kinds of style: the homely and the popular on the one hand, and the learned and classic on the other. The wide interval that may separate these two styles can be judged of by comparing the 'Pilgrim's Progress' with the 'Paradise Lost.'

**Expressiveness.**

This is a quality of style resulting from the power of words to echo by their sound and mechanical effect the meaning or sentiment that they are intended to convey. The suiting of the sound to the sense gives additional weight to the meaning, and therefore furthers the main object of the address. Many of the words of our language have a natural expressiveness, and they may be so joined in composition as to have an expressive structure. Pope has been admitted to have been often very happy in bringing out this quality. The following is an example:—

'If nature thundered in his opening ears,  
And stunned him with the music of the spheres,  
How would he wish that heaven had left him still  
The whispering Zephyr and the purring rill!"

Expressiveness is often preferred to elegance, as in cases where some coarse phrase carries with it a vigorous meaning. No one would object to Cromwell's saying of his Protectorate, that it was a device that had been before resorted to 'when this land was under the like hurli-burlies.'

**Freshness.**

This much-desired quality in all things presented to the senses or the mind of man may belong in very unequal degrees to modes of address. It is produced partly by mere novelty; partly by what, although not new, is in permanent contrast to routine or commonplace; partly by what is genial, loving, and hearty; and partly by high and consummate art. There are compositions which are fresh for the hour, and others that are so to every new generation. It is indeed possible to render the greatest compositions stale by harping too much upon the letter of them; but when moderately enjoyed, the creations of Homer, Aristophanes, Chaucer, Shakspeare, or Goethe, have an everlasting relish. The freshness of loving warm geniality attained its perfection in 'Don Quixote,' which will remain an eternal example of the qualities that make either a man or a book universally agreeable. Addison and Cowley are examples of the same fine-toned style of thought and feeling.

The revelations of the mystery and workings of nature break out with perpetual freshness upon the mind, just as its scenic beauty is a charm to every new-comer. Hence scientific compositions have all the delight of novelty at their first perusal. In like manner the practical devices of human life, the machinery, apparatus, and inventions of man for overcoming nature and organising human society, are a source of similar interest. The works that describe the ongoings of distant countries, as well as those relating to past ages, have the advantage that newness and strangeness of matter give to literary compositions; but in such cases the subject-matter, rather than the style, is the source of interest.

All expressions and descriptions that direct the view upon the outer world, have a healthier and fresher action on the mind than such as relate to inward feelings and emotions, or require an introspective effort. Self-consciousness, although as necessary in human life as sight or hearing, is naturally a weakening and debilitating action, and should be exercised only in a small proportion to the efforts of outward attention and regard. Shakspeare's description of Dover Cliff contains some examples of the inward or subjective reference, which will serve to illustrate what is here meant by it:—

'Come on, sir; here's the place—stand still. How dreadful  
And dizzy 'tis to cast one's eyes so low!

The crows and choughs, that wing the midway air,  
Show scarce so gross as beetles. Half-way down  
Hangs one that gathers samphire: dreadful trade!  
Methinks he seems no bigger than his head!  
The fishermen that walk upon the beach  
Appear like mice: and yon tall anchoring bark  
Diminished to her cock; her cock, a buoy,  
Almost too small for sight; The murmuring surge,  
That on the unnumbered pebbles idly chafes,  
Cannot be heard so high. I'll look no more,  
Lest my brain turn, and the deficient sight  
Topple down headlong.'

A combination of freshness, animation, and ease, will produce what is called the *light* in style, so much desiderated by all who aim at securing the patronage of the reading public.

The group of qualities next to be discussed, which allude to the various kinds of artistic effect, likewise contribute essentially to the result that we have last been considering.

(Taste, Elegance, &c.)

The qualities of Taste, being qualities superadded to the conveyance of meaning, are the secondary attributes of compositions whose object is to give direction or information, although they are the principal characteristics aimed at in the poetic and literary art. They are intended for the immediate gratification of a wide surface of varied human susceptibility, while the other purposes of speech relate to the practical ends of life, which may not be capable of taking on forms calculated to give artistic enjoyment. Neither elegance nor sublimity of expression is sought for in an act of parliament or a deed of conveyance.

The artistic qualities of style may be illustrated under the following heads:—

**Melody.**

The melody or music of articulate speech arises from the proper choice and ordering of melodious words and phrases. Certain combinations of letters have a more musical effect upon the ear than others; and the due alternation of long and short, emphatic and unemphatic syllables, under the guidance of an ear for the music of style, is calculated to gratify the sense of articulate melody. The following sentence from Milton has often been quoted as an instance of melodious composition:—'We shall conduct you to a hillside, laborious, indeed, at the first ascent; but else so smooth, so green, so full of godly prospects and melodious sounds on every side, that the harp of Orpheus was not more charming.'

**Comparison—Metaphor.**

The employment of comparisons serves the purpose of imparting clearness to composition in cases when a familiar and distinct image is employed to illustrate what is indistinct or obscure, as when the action of breathing is expressed by the example of a common bellows. But comparison has an artistic effect also, in consequence of the emotion that is produced by identifying and harmonising the remote and the unlike. The following lines from Chaucer, in his description of the Squire, contain several highly-artistic comparisons:—

'Embroided was he, as if were a mead,  
All full of fresh flowers white and red;  
He sung and fluted gayly all the day,  
He was as fresh as is the month of May.'

Metaphors are a species of comparison, where the likeness is not formally expressed, but implied by the actual use of the comparison in the room of the original expression. The necessity for metaphors arises from the difficulty of inventing terms in any other way for the more abstract and subtle kind of notions. Thus we speak of the 'head of a state,' the 'tail of a party,' the 'stream of time,' 'a sea of troubles,' 'the light of the world.' Like all other kinds of comparisons, of

which many species have been detailed by rhetoricians, metaphors may conduce either to clearness and force of meaning, or to ornament merely.

Epigram.

Epigram is pre-eminently an attribute of style, and not at all a quality of the thought to be expressed. It is a species of play upon words calculated to surprise and impress the mind in an agreeable way. It comprises antitheses, apparent contradictions, similarities, and contrasts of sound and sense; paradoxes, alliterations, puns, and some of the most striking felicities of metrical composition. 'When you have nothing to say, say it,' is an epigram; likewise, 'I am content, and I don't like my situation.' Butler, Pope, and Dryden abound in this peculiarity. A famous passage of Barrow, professedly illustrative of wit, applies almost exclusively to what we here understand by 'epigram.'

Metonymy—Circumstance—the Picturesque.

Metonymy is the name given to an effect produced by departing from the strict use of language, for the sake of singling out prominent circumstances—as, 'the city was put to the sword,' instead of 'the inhabitants of the city were slain.' Cromwell is said to have set up parliaments 'by the stroke of his pen, and scattered them with the breath of his mouth.' Instead of the main agent in producing an effect, some collateral or associated object is chosen, so as to make a more vivid image than a strictly accurate statement could produce.

Of the many figures of speech enumerated by the ancient rhetoricians, Metaphor and Metonymy are the only ones that express wide and comprehensive meanings; especially when Metaphor is generalised into *comparison*, and Metonymy into *associated circumstance*. These two ideas of comparison and contiguous association ally themselves with the two fundamental laws of the human intellect, expressed by the terms *Similarity* and *Contiguity*, and to this they owe the comprehensiveness of their grasp.

The choice of 'circumstance,' or of collateral particulars suitable to bear out the meaning of a principal term, or to assist in illustrating an idea, is a main point in literary art. Thus to take an instance in description:—

—'the whining schoolboy, with his satchel  
And shining morning face, creeping like snail  
Unwillingly to school.'

Or, still better, the illustration of the fop:—

'And as the soldiers bare dead bodies by,  
He called them untaught knaves, unmannerly,  
To bring a slovenly unhandsome corpse  
Betwixt the wind and his nobility.'

As another instance of circumstances powerfully built up for effect, take the following from Milton:—

'Nor uglier follow the night-hag, when called  
In secret, riding through the air she comes,  
Lured with the smell of infant blood, to dance  
With Lapland witches, while the lab'ring moon  
Eclipses at their charms.'

The *Picturesque* in literary execution is attained when the expression has been so conceived as to bring out a vivid picture:—

—'The sixth age shifts  
Into the lean and slippered pantaloon.'

To make words *paint*, as if with brush and canvas, is a very high effort of literary art; seeing that their nature is to drop a series of impressions into the mind, and not to hieit instantaneously an expanded scene before the view.

Sublimity.

This effect is produced by an expression of extreme power, grandeur, loftiness, expansion. Strength carried to its utmost pitch, and supported by adequate language, becomes sublime. When large and over-

powering objects are set forth in terms equal to their character, they excite the emotion of sublimity. The 'Paradise Lost' is full of sublime effects: were it not so with such a subject, it would be unendurable. As an example of a single stroke, we cannot do better than quote the following image from Shakespeare, which has never been surpassed as an expression by 'circumstance' of utter ruin:—

—'though the treasures  
Of nature's germins tumble all together  
E'en till destruction sicken: answer me to what I ask you.'

Beauty.

This is a very wide word, and if used in its utmost latitude, would cover everything included in artistic effect in general, so that the other particulars under the present head would be but varieties or forms of beauty. The beauties of style are unquestionably for the most part the result of harmony, fitness, and keeping in the various parts of the composition. The adaptation of the whole to its end, the order and harmony of all the particulars, the suiting of the style to the matter, and of the sound to the sense, all combined with the choice of images pictorially beautiful, and of words and cadences musically melodious, are the leading particulars that constitute the beautiful in literary art. When composition, considered as a fine art, perfectly succeeds in its aim, it must needs be beautiful. There may, however, be partial beauties, and beauties of many kinds. Every writer who has ever attained to the rank of a great classic, has owed a part of his success to the circumstance that his composition was such as to be considered a work of art. For the highest beauties of style we need only refer to Milton, Massinger, Addison, or Cowley, among the many great examples in English literature.

Pathos.

This is an effect depending on the tender susceptibility of human nature, on which are founded the warm affections of the heart, and which flows freely on occasions of misery, calamity, and pain. This susceptibility can be reached by verbal expression as well as by other means. Any literary work that delicately stirs the fountains of wounded tenderness is denominated pathetic. This class of compositions, unfortunately, has had occasion to be very numerous. The woes and sorrows, and the tragic doom of mortal men, have inspired lamentations and pathos, elegies and mourning, in every language under heaven. By the ordination of nature, the current of human tenderness is made to flow whenever distress has settled upon a fellow-man, and proves one of the great solacements of affliction. When either sorrow or compassion is aptly expressed in language, we have a stroke of pathos. Burn's 'Man is made to Mourn' is a highly characteristic example. The writings of the Old Testament, especially the book of Job, the Psalms, and the prophets, furnish abundant instances of the same nature. Nothing could exceed the pathos of Jacob's expression to his sons—'Unless Joseph come home with you safe, ye will bring down my gray hairs with sorrow to the grave.' Of recent compositions, the 'Bridge of Sighs' is a well-known example. When what we have previously denominated 'Feeling' is called forth by a tragic occasion, and expressed with becoming art, it produces pathos.

Ludicrous—Wit—Humour.

The feeling of the ludicrous being one of the emotions whose stimulus is highly gratifying to human nature, such a stimulus is frequently attempted by means of speech. As a *spectacle* that causes the ludicrous requires to be made up of some intimate conjunction of the dignified, lofty, or grand, with what is vulgar, mean, or contemptible, so the production of the like effect through *language* must generally imply the embodying of images or actions that possess the same mixture of

incongruity. For example, when Molière presents the celestial messenger of the gods sitting tired on a cloud, and complaining of the number of Jupiter's errands, Night expresses surprise that a god should be weary, whereupon Mercury indignantly asks, 'Are the gods made of iron !'

But confining our view strictly to style, a ludicrous effect is produced when the language is at variance with the matter on the score of dignity ; when a mean subject is treated in dignified terms, or a high subject in mean terms. Phillips's parody of Milton in the 'Splendid Shilling' is an instance of the first method; Lucian's 'Dialogues,' and Swift's 'Tale of a Tub,' exemplify the second.

*Humour* is the ludicrous with an infusion of the tender or the loving, and is a far more exquisite effect than the ludicrous alone. 'Don Quixote' is probably the greatest work of humour that the literature of the world has produced. Addison is also a very high example of the same combination.

Cumulative Richness.

A composition may contain few or many artistic excellences: it may be lean and thin, though not destitute of all merit; or it may be rich, copious, and luxuriant—overflowing in comparisons, pictures, sublimity, beauty, pathos, and humour. The taste of the writer may be severe and exclusive, or it may allow of all kinds of effects that can possibly sit upon a literary work. Of rich and massive productions, we have great examples in those of Rabelais, Shakespeare, Ben Jonson, Richter, and Swift. In the compositions of the seventeenth century in this country, a far greater luxuriance and richness was exhibited than we are accustomed to in the present day.

We proceed now to the various forms of verbal address and composition :—

SIMPLE FORMS OF ADDRESS.

In order that two or more men may act together, or manifest their sociability, there must be some means of making known each other's actions and intentions, or some signs given forth by one and understood by the rest. All the gregarious animals possess the power of establishing a common understanding throughout each herd. This effect is produced in the human species partly by the same natural expression as in the lower animals, and partly by articulate speech, by which the compass of the instrumentality is greatly enlarged. The following are a few cases of the simpler modes of mutual understanding :—

1. *Direction.*—This, to be effective, implies an accurate knowledge of the state of mind of the party addressed, as well as of the force of the expression used, a clear, slow, and deliberate manner, and such a degree of calmness and composure as shall avoid the liability to produce trepidation or terror. Telling a person the way to a place is a good case for practising the virtues and qualifications of a guide.

2. *Command.*—This should be expressive and dignified, but without any mixture of irritation or irascibility ; and while involving clearness and sufficiency of direction, it should contain no more explanation than is necessary for acting.

3. *Prayer, Intreaty.*—This implies primarily an appeal to the heart, or natural tenderness, of a fellow-man for the granting of some favour, but it has ultimately become a form including every kind of persuasive address. Taken in the primitive sense, the mode of intreaty should obviously be respectful, humble, and with a tone of sorrow and pathos, which will naturally touch the same strings in the person whose aid is besought. The praying form of speech has in all ages had its highest development in addressing the supernatural powers.

4. *Hostility, Defiance.*—The natural expression given by the tones, looks, and gestures, make this emotion very manifest to the hostile party. When words are selected to add to the force of the expression, they are such as

to signify revilings, threatenings, and the indication of hostility through all the relations and associations of life. Simple hostility is carried to its highest expression in the *curse*, which invokes on the head of the offender the enmity of the dreaded powers above.

5. *Encouragement.*—There is a natural language of encouragement and consolation suggested by tenderness and fellow-feeling ; and when extended by arousing intellectual associations through the means of a well-chosen address, it includes the suggestion of cheering thoughts and recollections, the holding out of promises and hopes, together with any form of assistance or guidance tenderly expressed.

6. *Interrogation.*—The conditions of this form of address are analogous to direction and command. There is required the same combination of clearness and composure of manner, with an appreciation of the state of mind of the party addressed.

7. *Response.*—Besides giving a statement in answer to an interrogation, this means the mode of acknowledging any form of address, or letting it be known that the effect intended has been produced. There are certain conventional phrases as well as gestures for conveying this acknowledgment—as 'yes,' 'indeed,' 'very well,' 'I understand,' and so forth. It is also conveyed by repeating the statement as conceived by the party addressed. Some form of acknowledgment to complete the understanding is necessary in all cases of direction, command, and instruction.

COMMUNICATION.

As distinguished from the modes of address above alluded to, the present head is intended to comprehend the cases where no immediate action is intended, but where statements are deposited in the mind of the hearer for action in some future day, or in some given circumstances whenever they shall occur. The distinction may be illustrated by comparing the word of command in the field with the directions to a sentry on taking up his post, or with the still more general and contingent directions of seeing that 'the state suffers no harm.' The rules of prudence, social and moral duty, are also of a very general kind.

Still farther removed from the most primitive forms of address are the statements of the facts of nature or life, when made without any reference to action at all; although such statements frequently form the links of action, as well as a gratification of intellectual curiosity. When we say, 'water dissolves sea-salt,' we imply no direction or guidance for immediate action; but we make a communication that may require to be acted on, or it may be treated simply as a statement of the order of nature, used as an interesting explanation of natural appearances. To see that such statements truly express the fact of things, is the province of Logic; but their intelligibility and effect on the mind are governed by Rhetoric.

This branch of the subject divides itself into three subordinate heads—Narration, Description, and Exposition: the first two are exemplified in travels and histories, the last deals with science.

*Narration* may be said to be the simplest and easiest effort of communication. A stream of words has a natural analogy to a stream of events or actions; hence narrative is the kind of address most easily invented. Ballads, songs, and heroic adventures, where the narrative is stirring and musical, like the conception of the deeds, are in all countries among the most primitive forms of composition.

*Description*, or pictorial expression, is a more difficult effort of invention, from there being a fainter and less suggestive analogy between still life and a flow of articulate utterance. The painter's instrumentality is the appropriate means of representation in this case. Besides the faintness of the analogy between the subject and the expression, there is the difficulty already alluded to of raising in the mind the image of expanded space by a dropping current of verbal impressions. Under the heads of *Travels* and *Historical Com-*

position we shall advert to the leading points involved in narrative and pictorial description:—

Of Travels.

The *traveller's point of view* furnishes the most natural way of conceiving places and transactions. The panoramic display of a country, or the gradual unfolding of scene after scene, is more impressive than any other method of bringing before us a wide and varied scene. The other methods of storing up in the mind the entire expanse of a town or a province, are the map, the *bird's-eye-view*, or mountain prospect, and the *statistical catalogue*.

To gratify the longings of men to enter into the living experience that lies behind the detail of exports and imports, of cargoes of tea and sugar, of silk and gold, of latitudes and longitudes, monsoons and rainy seasons, De Foe constructed his admirable fiction of 'A Voyage Round the World,' where he exhibits the entire ongoings of the seafaring and trading life through all the incidents of a circumnavigation of the globe. In this, and in 'Robinson Crusoe,' and in all his other life-pictures and histories, the author has adopted the point of view of a traveller, or of a single eye-witness, whose company the reader is supposed to keep. As one person can see as much as one other person can, this mode of description is perfectly adapted to the natural comprehension of men; while to compare and join together the observations of several persons standing in different positions is a very distracting operation. The life and manners of the heroic Greeks could not have been painted so vividly and intelligibly in any other form as in the adventures of Ulysses. The most fascinating poems and romances are those that run upon the thread of a single personage, as in 'Don Quixote,' or the 'Æneid' of Virgil.

With regard to *description*, as applied to the exterior world, or the appearances presented by surrounding scenery, the representation of which must be the basis of all other descriptions, the following points must be kept in view:—

1. In describing any complex thing whatsoever, we ought to commence by stating some great general or comprehensive feature of the whole, on which to distribute or attach the subsequent details. If there be anything that confers a unity on the object, that unity should be set prominently forth, and the individual parts should all point towards it. Naturalists commence with the *backbone* in the description of the animal frame. The primary conception of the earth is a *huge ball*, with rolling motion and variegated surface. The first epithet to be used in speaking of a mountain should give the general outline—such as, a vast conical hill, a steep ascent, a long ridge, a low flat eminence. In a mountainous country we fix upon the largest mountain range as the backbone, and represent the inferior chains as its members, and we derive from these the starting-points to the valleys, plains, and rivers; and in this way the detailed features preserve their places in our view of the whole. The word-painter shows his art in discerning, in the midst of complexity and detail, some comprehensive feature that gives wholeness or unity to the scene.

The *basis* of the description, or the leading feature to which all the rest has to be related, may be either an *outline* or a *centre*; it may proceed upon a general figure of the circumference and enclosure of the whole, or from some prominent and commanding point in the interior. The inside of a building requires to be described by outline: we must give, in the first place, the form and size of the floor, the height and the form of the roof, with some striking comparison or expression that may serve to bring out the feeling of the solid expanse in the reader's mind. This will be followed up by the orderly detail of the contents; and it is well to repeat and indicate in various ways the great primary notion of the form; for if this once drops out of the view, the whole picture crumbles into confused fragments. Satan's palace in 'Paradise Lost' is admir-

rably pictured by the appropriate expression of space and outline:—

— 'The ascending pile

Stood fixed her stately height; and straight the doors,  
Opening their brazen folds, discover wide  
Within, her ample spaces, over the smooth  
And level pavement; from the arch'd roof,  
Pendent by subtle magic, many a row  
Of starry lamps and blazing cressets, fed  
With naphtha and asphaltus, yielded light  
As from a sky.'

A plain enclosed by mountains is a proper subject for *outline* description. Seas and lakes, encampments, and all kinds of scenery and expanse whose character and internal arrangement are determined by their enclosing boundary, or by the form of their surface, must be treated in the same manner.

In picturing towns, the basis ought in general to be a *centre*, or some prominent object that governs all the rest, or that is sufficiently important to fix the attention as a leading feature of the scene. The river running through or past a town is usually fixed on for this purpose; or if on the sea-shore, the line of coast may be chosen. Next to these, a great natural valley or a central eminence will serve the purpose; or, lastly, some of the great thoroughfares of the interior. After choosing out a main trunk in this way, and impressing it sufficiently on the mind, we naturally follow out, first its larger, and then its smaller branches; but on all occasions we are to keep starting from the *great centre*. Thus the order of conceiving and describing Edinburgh would obviously be to take, *first*, its situation on the Forth; and *secondly*, its great natural division into the Old and New Towns by the valley along Princes Street; and in specifying a particular spot or locality to a stranger or to a reader, it would be proper always to set out from this central tract until such time as it was thoroughly impressed on the mind; after that we might refer to secondary trunks, such as High Street, the main artery of the Old Town; and the parallel to Princes Street on the north, including the body of the New Town. But until the Princes Street line has been repeated many times, we ought not to make use of a second starting-place. If the reader, or the transient visitor, retains any impression at all, it ought to be Princes Street, with its terminations and boundaries; if he recollect something more than this, it ought to be High Street; and so on. The description and the repetition should be so conducted, that the main trunk may be the most deeply impressed of all, and that the principal branches from it may make the second-best impression; while the largest offshoots from these should rank third in order of impressiveness; and what is first forgotten should be the minuter ramifications—such as the offsets of the interior, and the lanes and minor localities of the scattered suburb. Almost every town may be simplified on this principle. In London, after the Thames, the Strand and Holborn lines are the obvious basis of a traveller's conception. Rome has for its great trunks the river and the Corso; and for its secondaries of reference, the Vatican, the Castle of St Angelo, and the Colosseum—all which have been attended to by Dickens in his picture of the city.

A river, a valley, or a highway may often form the appropriate centre of the general scenery of a district of country; and consequently the description should be shaped with a view to these being vividly impressed. If the continuity of the main line of reference is broken up, the whole scene reels in the imagination of the reader, as if the ground gave way beneath his feet.

2. In description, as practised under the traveller's point of view, it is an important maxim never to let the reader lose hold of the dominant circumstances that rule the perceptions and feelings of the observer. There are certain points that determine, in preference to all others, the state of the mind in any given situation. If we wish to make a second person, as it were, stand where we stood, and see what we saw, we must, in the

*first place*, make him clearly to conceive the *footing* or support, the nature of the ground, and the manner of resting upon it. We should indicate whether our footing was firm or loose, rough or smooth, ascending or descending, and whether we walked, stood, lay, rested, or rode. There will of course be the supposition that we were sustained somehow; but it is essential to let it be distinctly understood what was the exact circumstance of this first and most indispensable contact with the outer world; and the more surely and vividly this is conceived, the more perfect will be the understanding and conception of all other things.

In the *second place*, there should be no mistake about the state of the *light* that prevails at the time, whether clear sunshine in a blue sky, or otherwise; or if, in reference to the night, whether the moon or stars were visible. The poets are particularly attentive to this particular—

‘He ceased, the whole assembly silent sat,  
Charmed into ecstasy by his discourse,  
Throughout the twilight hall.’

In the *third place*, it is necessary to indicate decisively the *forward prospect*, which, next to the actual footing, engrosses the solicitude of the mind, and determines the bent of the feelings. It ought to be pointed out whether the prospect is free and open, or shut and encumbered; whether it spreads out far, or closes near at hand; whether it rises or descends. In our onward movement, this determines our hopes and fears, or the complexion of the future; and if we are at rest, it controls our vision and the trains of thought suggested to the imagination.

In the *fourth place*, and next to the forward prospect, the writer should make known the *side hedging* of his path, the close confinement, or free expansion on the right and left; for this, too, will affect his feelings and meditations.

In the *fifth place*, the roofing overhead should be included. In the open air, this would refer to the state of the sky; but it becomes a more essential point of description if under a roof.

To these five points may be added the *sounds* that salute the ear, and any other sensations that are material under the circumstances. No human being can escape from the effects of the various influences now enumerated: they press most intimately upon the whole being; and one person cannot enter into the mind and feelings of another in a different position, without conceiving all of them exactly as they existed. While they remain uncertain and unfelt, all subsequent description of spectacle, motion, sound, and life, is mere fancy-work or aerial pictures, which a second party has no personal relation to, no human sympathy with, no feeling of bodily presence among.

With regard to description in general, as applicable to all cases where a complex object or scene has to be represented to the view, the leading maxim, as already hinted at, is to combine a *type* of the whole with an *enumeration* of the parts. Some comprehensive designation that may spread out the main features of the object is indispensable to the description; and within this the details may be arranged in proper form and order. The following is a very simple instance from Milton, which seems as if it could not have been stated otherwise than he has done; but it shows itself in carrying into complicated cases the method that appears self-evident in easy cases. The words in italics mark the comprehensive designation or type, the rest of the description giving the details:—

‘They plucked the *scathed hills*, with all their load—  
*Rocks, waters, woods*—and by the *shaggy tops*  
Up-lifting, bore them in their hands.’

Carlyle’s description of the town and neighbourhood of Dunbar, the scene of Cromwell’s decisive victory over the Scotch, is rendered vivid and conceivable, in consequence of his always introducing particulars and

details by terms and epithets that are at once comprehensive and picturesque:—

‘The *small town* of Dunbar stands *high and windy*, looking down over its herring boats, over its grim old castle, now much honeycombed, on *one of those projecting rock-promontories* with which that shore of the Firth of Forth is niched and Vandyked as far as the eye can reach. A beautiful sea; good land too, now that the plougher understands his trade; a *grim niched barrier of whinstone* sheltering it from the chafings and tumblings of the big blue German Ocean. Seaward, St Abb’s Head, of whinstone, bounds your horizon to the east, not very far off; west, close by, is the deep bay, and fishy little village of Belhaven: the gloomy *Basin* and other rock-islets, and farther, the hills of Fife, and *foreshadows of the Highlands*, are visible as you look seaward. From the bottom of Belhaven Bay to that of the next sea-bight St Abb’s-ward, the town and its environs form a peninsula. Along the base of which peninsula, “not much above a mile and a-half from sea to sea,” Oliver Cromwell’s army, on Monday, 2d of September, 1650, stands ranked, with its tents and town behind it, in very forlorn circumstances.

‘Landward, as you look from the town of Dunbar, there rises, some short mile off, a *darky continent of barren heath hills*; the Lammermoor, where only mountain sheep can be at home. The crossing of which by any of its boggy passes and brawling stream-courses no army, hardly a solitary Scotch packman, could attempt in such weather. To the edge of these Lammermoor heights David Leslie has betaken himself; lies now along the utmost spur of them, a long hill of considerable height. There lies he since Sunday night, in the top and slope of this Doon Hill, with the impassable heath continents behind him; embraces, as with outspread tiger-claws, the base-line of Oliver’s Dunbar *peninsula*.’

#### Of Historical Composition.

Narration is, in the simplest class of cases, an easier effort than description; inasmuch as we have merely to enumerate the objects or events one after another as they rise to the view. But since, in the greater number of instances where narration is of any importance, the successive events present individually a wide and complex surface, there is demanded for each an appropriate description; and a succession of descriptions will thus make up the narrative.

This is particularly true of historical narration, or the detail of the larger transactions of masses of men on the face of the globe. History is properly a compound of narration and description: it has to express the mighty march of nations through the ages of time.

There is, however, this peculiarity in the case, that the scene of action remains the same in all its larger features. The surface of the earth, the mountains, valleys, plains, and rivers, where men live and act, continue the same; and they have, therefore, to be made known once for all in the case of each separate people that remain attached to one territory. Although this diminishes the difficulty of the historian, yet there is required considerable exertion on his part to make an ordinary reader conceive with perfect clearness the features of a foreign country. The following are a few of the requisites of historical composition, considered in its purest form; or with as little reference as possible to the expositions of doctrines and opinions, and the criticisms of character and conduct, that mix so largely in the greater number of historical works:—

1. It is essential that the ground where the transactions have occurred should be distinctly pictured forth at the outset, and maintained steadily in view by the subsequent references; in other words, the geography should be fully comprehended by the reader before commencing the history. There will, of course, be certain portions of the geography more pertinent to the narrative than others, and these will naturally be the most insisted on. Thus if the country subsists largely upon its mining operations, the mines must be promi-

nently described in the preliminary survey. With regard to geographical description in general, in which our schoolbooks err deplorably, the principles of description already laid down must be faithfully observed. We must start with a comprehensive sketch of the surface, by stating the great outlines and the prominent central-points, and branch out from these in every direction, in a regular order, and with constant reference to the main features. The *expanded space* occupied by the country should be steadily maintained in the view, there being a constant tendency in the uncultivated mind to allow the territorial expanse to collapse into a jumble of confused particulars, and thus destroy the chief grandeur of the scene. The description of a country by a bare catalogue of its coasts, mountains, rivers, islands, chief towns, &c. is to be considered as a gross violation of every principle of descriptive or expository art. In some of the larger geographical works, such as Ritter's, and the articles on Geography in the 'Penny Cyclopaedia,' the *proper order* of description is in general well exemplified.

The full geographical detail includes, in addition to the situation, features, and climate of the country, the nature of the soil and strata, the vegetable and animal life that flourish in it, and the population considered as to its race and connections with the great human family.

2. The second principle of historical composition relates to the tissue and substance of the narrative itself. *A history ought properly to be a series of pictures or cross sections of a nation's existence appropriately selected from different epochs, with an intermediate narrative to explain how the one became transformed into the other.*

It is to be understood that mere existence does not furnish matter for history. If a people have got themselves into a quiet routine of being born, growing up in the exact footsteps of their fathers, and dying, to be succeeded by others like themselves, and continuing thus from generation to generation without progress or change—all that can be stated of such a people is, how they exist at any one time, or what are the incidents of a single generation: there is no material for a continuous narrative. There are many societies very nearly in this predicament: the Chinese are an example of a people with a high civilisation, but with very little tendency to change; and most of the savage tribes of America and Africa, and the wandering hordes of Asia, are still more destitute of the subject matter of a history. Progress, change, expansion, development, all that we mean by civilisation, form the substantial matters of historical narration.

The most prominent spectacle usually presented by nations is their quarrels with their neighbours, with the struggles and wars that ensue, and the loss or gain of territory incident to contests. Every kind of strife, contention, and combat, where large interests are at stake, and the human powers exerted to their very utmost, has an exciting effect on the beholder, and makes a stirring narrative to a reader. The historian, anxious to make his work as little dull as may be, is glad to have such matters to throw into it; indeed they are apt to be the chief things to seize his own attention. Hence the real substance of history has often been concealed by the prominence of the exciting and bustling drama of battle, victory, and death. The internal struggles of a nation for the possession of the sovereign power have the same dramatic interest, in addition to their importance in the real history of the people.

Although it is impossible to lay down a universal formula for historical composition, it may nevertheless be shown that conveniently-chosen epochs for cross sections, or complete pictures of the total life and existence of each people, ought to be the great divisions of the history; and that the narrative should dart between these, so as to explain upon general laws of progress and change how one came to be transformed into another. The selection of the epochs will be determined by the character of each case; the number of

them will be greatest in the histories where progress has been most rapid, as in the history of Greece; and the period assumed must depend on the time that would best represent a full and average natural existence. Guizot's 'History of Civilisation in France' exemplifies in some degree this choice of epochs for a detailed picture of social existence.

The arrangement of the details of the entire existence of any one people is a matter of prime importance. It is desirable that the plan should be as simple as the subject admits of, and that one plan should be adhered to as much as possible. If all historians could be made to agree upon the same scheme of descriptive array, the comparison of different peoples and different ages and degrees of civilisation would be very much facilitated. We shall here indicate the outline of an arrangement which seems to be both natural and comprehensive:—

The geography will have to be given once for all in the first sketch that is made; but as the conception of geographical features is somewhat difficult to sustain, repetitions and frequent references require to be introduced here and there all through.

The geographical picture being supposed to be complete up to the point of describing the race and features of the population, the detail of civilisation, or of the arrangements instituted by the intelligence of the people for improving and elevating their condition, will commence. The first class includes the industrial arts, or the arts of agriculture, mining, manufacturing, commerce, &c. These express the mechanical action of the people upon the material earth around them, and will be intimately related to the physical geography. The agricultural arrangements must be governed by the soil and climate; the mining by the rocks; and the manufacturing by the raw material and the facility for mechanical power; while the commercial advancement depends on the means of easy conveyance by seas, rivers, &c.

The second portion of the picture might include the arts of training or rearing living beings—vegetable, animal, and human: the third would refer to the arts of health and healing: the fourth, the arts of intercourse, or the arrangements to facilitate social operations. The chief heads of this comprehensive branch are—language, the forms of business, and etiquette; the arrangement of towns, markets, and places of resort; the classification of the population for easy reference, as by directories, gazetteers, statistics. The fifth branch is the government in all its parts and bearings: the sixth includes the state of morality, in theory and practice: the seventh, religion: eighth, the scientific development of the people, or their acquisitions in all the systematised branches of knowledge. This is the great central feature of the civilisation of mankind taken as a whole. Ninth, the state of the fine arts: tenth, the character of the literature: lastly, the advances made in the art of living, or in all the devices expressly adapted for enlivening and gratifying the course of human existence.

It would require a lengthened illustration to do justice to the exposition of any one of these heads; but, taken together, they seem to imply all that it is desirable to know in reference to any one society. When we go back to past ages, it is difficult to recover the desired information, so as to complete the picture of a bygone epoch. But the possession of some general scheme of this character is essential to the historian, in order to give him a distinct hold of the desiderata of research, and to enable him to find a place for everything that comes under his notice. The mutual dependence of all the great branches of social existence supplies a check to test the accuracy of statements, as well as a means of inferring what is not separately known; and this mutual dependence is most evident when a natural arrangement of the subjects is arrived at.

One of the best examples of the detailed analysis and portraiture of a people at some one epoch is afforded in the first book of Mill's 'History of British

India.' The display of the institutions and whole existence of the Hindoos in that book will render the scope of the above remarks perfectly intelligible to any one desirous of studying the subject. So little have the Hindoos changed within historical periods, that Mr Mill finds one display of their existence to be sufficient; but in a growing country, the array of social existence would have to be gone over more than once. In England there are various epochs that could be fixed upon: a Saxon epoch, a Norman epoch, one at the reign of Elizabeth, a Puritan epoch, and one in the early half of the last century, would be essential; and a considerable amount of explanatory narration would be requisite to connect each of these with the preceding in the way of causation.

These remarks refer to the total march of an entire people, and apply only in a small degree to partial histories, such as histories of science, art, commerce, medicine, &c.; but wherever the stream of events is massive or complicated, the plan of treating it by well-chosen cross delineations is advisable.

History, from the largeness of its subject, is capable of a very wide variety of treatment; and many successful works have been produced, both in ancient and in modern times, although with very different kinds of merit. It is not a little remarkable that the oldest historical composition of pagan antiquity—the work of Herodotus—should come up more nearly than almost any production that could be named to the standard of composition now laid down upon the most advanced scientific considerations that we are able to bring to bear upon the subject. In that great epitome of the ancient world, all the nations known to a Greek inquirer of the fifth century before Christ are pictured forth with vividness and precision, and the classification of details is quite equal to anything employed in the greater number of works of subsequent ages.

Of recent historical compositions, 'Mill's British India' is the greatest English work, viewed according to the exposition now given of the proper tissue and structure of history. 'Guizot's History of Civilisation in France' is the most remarkable foreign production on the same model. The 'History of Greece,' now in course of publication by Mr Grote, promises to be a work worthy of the greatest people that has yet appeared on the face of the globe.

Exposition.

This brings us to a mode of address different from any that we have as yet alluded to—namely, the expression of scientific truth, or of the great laws and uniformities of the appearances and events that may be discovered in the world. If the laws and successions of nature's phenomena appeared on the surface of things, or were as open to ordinary observation as the course of the seasons, or the different scenes of a theatrical performance, then a plain *narration* would be sufficient to indicate the stream of cause and effect, or the laws of natural phenomena. So, if the uniformities of coexistence, the attributes that always accompany one another by the ordination of nature—such as the properties that join together in a vegetable, an animal, or a metal—were as apparent as the furniture of a household, or the array of a mountain prospect, then ordinary *description* would suffice for the exposition of nature's profoundest collocations. But it so happens that neither ordinary narration nor ordinary description is sufficient to express scientific truth, or the comprehensive laws and secret processes of creation. Such is the structure of the universe, that an artificial machinery of expression, having often very little to do with the obvious appearances of things, is required to embrace it by the understanding, and to make it known to other men's minds.

The artificial machinery of language suited for the expression of science is fully explained in our number on Logic; and it belongs to that science to pronounce on the accuracy and sufficiency of any form of language to contain rigorous scientific truth. The nature

of abstractions, definitions, propositions, and classifications, is therein set forth. And to Rhetoric belongs, not the art of attaining true abstractions and propositions, but the method of shaping them for easy communication and diffusion among men. The natural mind, which can easily adapt itself to superficial narration and description, finds the comprehension of scientific views hard and unpalatable; and although these contain in a very short compass a boundless range of insight into the world, and give the power of explaining complicated appearances, of predicting the future, and of finding means for the working out of desirable ends, yet such is the difficulty experienced in acquiring possession of them, that high scientific attainments have hitherto been among the least usual of human acquisitions. The progress of science on the one hand, which in many respects tends to simplicity, and of rhetorical method and expository devices on the other, tend to make scientific truths more attainable by the mass of men.

It has been sufficiently explained under Logic that there are two kinds of science—the pure or abstract, and the mixed or concrete: the one has reference to the distinct kinds of phenomena that the world presents—such as phenomena of quantity, considered in mathematics; of force and motion in mechanics; of heat, light, electricity, &c. in physics; of atomic affinity in chemistry; of vital properties in physiology; and lastly, of mind and social agencies in the great sciences of humanity. The other, or the mixed sciences—such as geology—do not confine themselves to a single class of pure natural phenomena, but lay hold of some local or practical department of nature, where two or three different primary forces may be at work. Thus geology involves mechanical, physical, chemical, and vital forces, all taken together. So the practical science of engineering brings together mathematics, mechanics, physics, and chemistry, to attain some gross practical end. It will be seen that the mixed sciences deal with matter more in the lump than in the case of the others; hence they come more nearly within the scope of ordinary description or narration. Unless they are treated of solely by combining the machinery of the pure sciences, they are the more intelligible and popular of the two kinds. Natural history is the designation of a whole nest of concrete or mixed sciences; and if they are kept apart from the deep considerations of the pure sciences of physics, chemistry, and life, that serve for their complete explanation, they are calculated to be highly popular.

The leading maxims to be observed in the exposition of the abstract sciences—such as mathematics, physics, &c.—must be ruled by the consideration, that each of them contains a series of artificial notions or conceptions that can work themselves into the human brain only by a slow and deliberate process. Hence the strictest orderliness must be observed in arranging their constituent ideas, so that each may be presented only after all others necessary for conceiving it have been fully mastered. Scientific acquisition is a work of severe discipline; and the simplest steps should be securely fixed before any attempt is made to go beyond them. The art of the teacher lies wholly in attending to this. The greater number of the abstract sciences fall properly to be taught by the schoolmaster, and not by unassisted books. But when it is desired to make science possessible by a reader going through a book at an ordinary pace, the following procedure must be adopted:—

1. The propositions or abstract notions must be stated in the clearest possible form.
2. Each proposition may be expressed in two or three various forms of language, but there should be some one form adopted for remembering it by. A vivid epigrammatic statement of a proposition, either before, or to sum up and condense, the exposition, is always very effective, and indeed necessary for the sake of the memory.
3. It being understood that only one proposition or

abstraction is stated at a time, each must be followed up by a series of *examples* or instances chosen from things familiar to the reader. The examples at first should be extremely simple, but in the end they should become more difficult, so as to show the power of the principle to throw light upon them.

4. Besides explaining by examples or cases in point, we may explain by *illustration*, or by similes or parallels, from some class of subjects more palpable to the understanding than the one treated of; as when we illustrate the conflict of motives in an individual mind by the visible contests of animal strength. The caution in the use of illustrations is to see that they do not bring in confusing ideas.

The writer of a manual for schools, or of such a book as Euclid's 'Elements,' gives a whole string of definitions, containing strange and unfamiliar notions, without the slightest pause; but the popular writer must take care to bring on upon the stage only one new notion, or technical phrase at a time; and each must be spread out, repeated, exemplified, and illustrated, by easy exposition, before the writer ventures upon a second. One of the great burthens and pains of human life, is to work with half knowledge or half capacity; and this is never more felt than with the reader of a scientific book, where novel conceptions flow in upon him faster than he can fix them.

It has been thought that the concrete objects of the world are not sufficiently kept before the mind in abstract expositions. This is true to a certain extent; for the doctrines of addition, subtraction, multiplication, &c. and the theory of decimal notation, which is the entire foundation of arithmetic, might be rendered much more intelligible by the use of objects—such as wooden cubes made up into rows and squares. This method has been carried out in the system of Pestalozzi. On the other hand, the necessity there is for creating ciphers, symbols, and other artificial apparatus, shows that we are committed to a peculiar region of things; and we must make up our minds to comprehend and use the abstractions themselves, independently of the concrete forms. In the most popular scientific book of our day, Dr Arnett's work on *Physics*, where concrete illustration is carried as far as it has ever been in an abstract exposition, the author, instead of proceeding gradually from the concrete to the abstract, finds that the nature of his subject requires him to place at the very threshold the four most abstract notions that his subject contains—namely, *atom*, *inertia*, *attraction*, *repulsion*; and he calls upon his reader to comprehend these as a preliminary to all the rest.

In the other class of sciences—such as *Natural History*, *Geography*, *Morals*, &c. which, instead of being universal and theoretical in their subjects, are more or less either local or practical—a different style of treatment is possible. In the exposition of these there are two great maxims never to be lost sight of:—

1. In endeavouring to make the reader comprehend a class of objects—of animals, trees, shrubs, rocks, strata, or whatever else—it is essential to fix the attention first upon some one actual specimen, and to describe it on all sides, with such a degree of explicitness and fulness, that the entire object shall be completely familiar to his mind. This being once done, other individuals can be defined and made known by their *differences* from the typical one; and whole classes can be chalked out and discriminated. If one individual has been thoroughly conceived in all its parts, then every other individual may be conceived with the same fulness when its difference is made known. Thus the knowledge of the vertebrate series of animals is best secured by a profound acquaintance with the human anatomy: this once achieved, it requires only an attention to the points of distinction to have an equally profound and thorough acquaintance with every individual of the vast series. Now that a universal nomenclature has been completed by the labours of Professor Owen, such a transition from the human type to the vertebrate series is rendered a comparatively easy task.

But the grasp of the whole will never be secure unless the knowledge of the *typical instance* is certain.

2. In bringing before us some object that can be represented only by a series of descriptive references to other things, it is necessary to commence with the known, and proceed by known connections to body forth the unknown. The exact state of mind, in respect to knowledge, and interest or likings of the person addressed, must be clearly kept in view. The interest of a description increases by the number of ways that it connects itself with our personal experience. Thus to describe a manufacturing process—say the manufacture of soda—the method is to commence it at the stage where the hearer is familiar with the things employed—namely, at the employment of sea-salt and oil of vitriol—and then give every successive action in language that recalls familiar objects.

The description of animals is rendered intelligible and interesting by dwelling upon the points that have a parallel in human life; as on where they get their living, how often they eat, when they sleep, how they spend their day, the length of their life, their hardships and difficulties, their pairing, procreation, and parental solitudes, their faculties and capacities, their means of defence and offence. The vegetable and mineral world has an interest by relation to human uses and wants, as well as to the uses of the animal creation at large. If there is any animal or vegetable familiar to us—such as our household quadrupeds and insects—the naturalist has a good hold on our attention, if he wishes to lead us into the hidden minutiae of their structure and existence. The natural history of household animals would make a work of universal and unfeeling interest.

Besides the subjects slightly alluded to in the foregoing remarks, exposition includes a vast range of compositions in politics, law, theology, morals, and many other sciences, besides the wide domain of practical business, where it is required along with the other literary efforts of narration and description.

#### PERSUASION.

We are now to consider the forms of address suitable to influencing the conduct or activity of men. In addition to the spontaneous impulses of any given individual, there are many ways of acting upon him from without that are equally effectual in determining what he shall do or abstain from doing. He may be made to act through external compulsion, for example, or by the command of his superior, which is moral compulsion. But apart from these, he may be led into action by sympathy with others, and likewise by the influence of the mere will and presence of one who has no means either of coercing or of commanding. But persuasive address differs from all these modes of inducing action upon human beings. It implies that some course of conduct shall be so described or expressed as to coincide, or be identified, with the active impulses of the individuals addressed, and thereby command their adoption of it by the force of their own natural dispositions. A leader of banditti has under him a class of persons whose predominant impulse is the attainment of plunder; and it becomes his business to show them that any scheme that he desires them to carry out will achieve this object. A people with an intense overpowering patriotism, like the old Romans, can be acted on by showing that the good of their country is at stake. A Christian assembly is supposed to be capable of being roused into action by the prospect of extending the power and influence of Christianity in the world. In a comprehensive survey of the Art of Persuasion, the following things deserve to be considered:—

1. The ends most usually sought by means of persuasive address. These are innumerable in their detail, but the purposes of an exposition will be served by singling out a few of the more prominent. In the oratorical professions of the preacher, the pleader, the leader of political assemblies, the newspaper writer, there are

certain well-known objects sought to be attained. In opposition to individual egotisms and peculiarities, it is desired to induce a course of action conducive to the interests of the world, or the community at large, or of some part or section thereof, or, it may be, of some single person. In moral and religious address, the larger and nobler ends of one's being are sought to be impressed and made predominant over present and passing impulses. At other times, the thing aimed at is to make the reason, which embraces the comprehensive good of the whole, to prevail over the passions and instincts. It is often desired to produce *belief* or conviction in men; which means, not immediate action, but a general disposition to act in a particular way when certain occasions arise; as when we wish to prove that the most effective kind of local government is a combination of local authority with the wisdom and experience supplied by a central power. And when men are agreed as to the thing that they should do, much dispute may arise as to the manner of doing it; and the author of each different scheme has to devise ways and means of carrying the minds of the audience with his proposal in preference to the others. There can be no doubt as to the highest and noblest ends of persuasion—which are to sway the minds of men in favour of the universal, the eternal, and the true, as opposed to the sectarian, the temporary, and the false. To induce men to act upon a delusion is a poor triumph. The projectors of bubbles, the inventors of quack medicines, the dealer in puffery and unsubstantial commodities, the panderers to the mob, are all highly persuasive with little art; it being one of the weaknesses of humanity to be impressed by dazzling hopes and prospects. It requires greater genius and skill to induce men to adopt what will succeed in the end.

Although the usual end of persuasive address is to turn the existing dispositions of men to some immediate account, it yet falls within the scope of such address to inflame and cultivate the dispositions themselves, as in the work of the preacher and teacher.

2. It is essential to persuasion that the speaker should be accurately acquainted with the minds and dispositions of his hearers. The perception of character is indispensable to an orator's success: if he mistake his audience, he cannot hope to move them by his address. This thorough knowledge of character is an attainment come at in various ways. The primitive source of our knowledge of our fellows is the consciousness of ourselves, and the assumption that other persons are made after the same fashion. A clear and vivid consciousness of self—that self being abundantly rich and varied—is the foundation of all accurate knowledge of other men's minds. Next to it is sympathy, which implies that we readily fall into the states of mind indicated by the outward expression given forth by those about us. Like the primitive consciousness of self, this differs very much in different individuals. It is the chief corrective of the false assumption that all other men are exactly what we find ourselves to be. The third source of knowledge, and the next to sympathy as a means of enlarging the narrow primitive conception, is the steady observation of men's whole actions and ways, and of everything that shows their dispositions and characters. We have to note the things that attract and repel them, their usual incentives to action, together with their own expression of what influences and guides them. We can go still farther, and experiment upon all these points by endeavouring ourselves to control their actions by suitable management. This combined observation and experiment is the usual recognised source of a knowledge of mankind. Abundant opportunities of seeing men, and acting with them, against them, and on them, are supposed to be the true and only means of being accomplished in this knowledge. But, after all, it is only a valuable supplement of self-consciousness and sympathy. The fourth source of the knowledge in question is furnished by the generalised laws and properties of mind included in the science of mind.

But for the purposes of oratory, as practised in our day, this source of knowledge need not at present be discussed. It is evident, on the whole, that a clear consciousness, sympathy, and observation of the impulses and active dispositions of men, confirmed by repeated experimenting upon those very dispositions, are indispensable to persuasive address.

It is a necessary consequence of this knowledge that it should enable a person rapidly to discern a character from its appearances, so as to perceive the dispositions of strangers in a very short time, and to trace instantaneously the effects produced on an audience in the exercise of the oratorical art.

3. Next to a distinct end, and a thorough perception of the moving forces of the assemblage to be wrought upon, comes the great constructive process of the art, which is so to shape the statement of the end, that it may connect itself with the most powerful impulses and convictions of the party addressed. The capacity for this must spring from a rich and accomplished mind, able to discern all the connections and aspects of a subject that are likely to touch the motives or coincide with the dispositions of an audience. Thus, if we examine Milton's apology for unlicensed printing, we shall find that the vast range and compass of his knowledge and conceptions enabled him to lay out with unparalleled fertility the whole subject of the connection of a free press with the welfare and the elevation of the human kind. We may find men more at home in adapting a subject to the exact standard of the ordinary class of minds, so as to be capable of securing a great extent of practical conviction; but nowhere has any one addressed with more varied and powerful persuasives all that is high, generous, and noble in humanity, than Milton in this instance. A genuine, practical, business orator would not have struck so high a key; his object being to gain an end solely, he would have confined his arguments and address to that side of his audience that they could be drawn by. The successful pleaders at the bar furnish the best examples of this last species of oratory.

It being assumed that fertility of intellectual views, with a capability of expressing them in language, are at the basis of persuasive power, it is possible, nevertheless, to assign the precise peculiarities of art which affect a speaker's success. The ancients were well aware of the necessity of a wide general cultivation to make an orator, while they at the same time pointed out the conditions that had to be superadded in order to successful address. These conditions will likewise serve to indicate the precise nature of the capacity and cultivation that best contribute to oratorical efficiency, so as to discriminate between these and the talents and acquirements that point more expressly to other intellectual excellences:—

1. The persuasive mode of composition must frequently be based on some of the preceding modes of simple communication—namely, narration, description, and exposition—but in such a case, these will be so shaped as to influence the minds of the persons addressed towards some particular end. Thus the narration of the facts in an ordinary law-pleading is usually conducted so as to produce a bias in favour of one side; the circumstances that have this tendency being put prominently forward, while the others are kept in the shade. In like manner the exposition of doctrines or principles is involved in a great number of the attempts at persuasion. A beautiful example of an exposition, conducted with high oratorical effect, is furnished in the following extract from one of the speeches of Demosthenes. It professes to be a definition of Law:—

‘The whole life of men, whether the state they live in be great or small, is governed either by Nature or by Law. Nature is irregular and capricious; Law is definite, and the same to all. When the natural disposition is evil, it frequently urges to crimes; but the laws aim at the just, the good, and the fit: these they search out, and when determined, they publish as the regulations to be followed by every one alike. To these

obedience must be rendered on many grounds; but most of all on this—that *law is the invention and gift of the gods, the resolution of prudent men, the corrector of voluntary or involuntary wrong-doers, and the determination of the state at large, which is necessarily binding on all its citizens.*

Here the high function and claims of law are stated and enforced by being allied with the most commanding and august sanctions that the world can furnish.

The following is a modern instance of the same mode of address, where an exposition is the basis of an appeal to the convictions and active principles of men. It is on the subject of slavery; and the author (Robert Hall) intends to produce in his readers a strong feeling of hostility to the slave system by a mere exposition of its essential character:—

‘That slavery is the most deplorable condition to which human nature can be reduced, is too evident to require the labour of proof. By subjecting one human being to the absolute control of another, it annihilates the most essential prerogative of a reasonable being, which consists in the power of determining his own actions in every instance in which they are not injurious to others. The right improvement of this prerogative is the source of all the virtue and happiness of which the human race is susceptible. Slavery introduces the most horrible confusion, since it degrades human beings from the denomination of persons to that of things; and by merging the interests of the slave in those of the master, he becomes a mere appendage to the existence of another, instead of preserving the dignity which belongs to a reasonable and accountable nature. Knowledge and virtues are foreign to his state: ignorance the most gross, and dispositions the most depraved, are requisite to reduce him to a level with his condition.’

2. Argument, or proof, which is the medium of bringing the conviction of truths home to men’s minds, must be a frequent means of persuasion. If the persons addressed were always of a strictly logical turn of intellect, then the soundest reasons would be the most persuasive; and the rhetorical method would strictly coincide with the logical. But as this is not the case, there are various resources used in the statement of arguments that do not belong to the rigorous demonstration. Indeed there are certain devices, known by the name of arguments, that do not in any degree imply proof—as the *argumentum ad hominem*, and the *argumentum ad verecundiam*, or appeal to authority, neither of which concern the absolute truth of the question at stake. It is very common also to appeal to the inconsistency of some practice, or to show the impossibility of carrying out the principle in all cases. This ought to have more weight than it usually has with the mass of men, who care for immediate objects more than for rigorous thoroughgoing consistency.

In conducting a chain of arguments, it is usual to begin with a full and explicit statement of everything that is admitted by all parties. There is a great advantage in doing this, as it may be possible to shape such a statement so as to suggest inferences of use to the cause in hand.

There is always a powerful effect produced by stating a case so as to appear not only highly credible and probable, but also exceedingly *plausible*, which is done by making the whole case appear to coincide with the familiar experience and natural expectations of the hearers.

3. Another important device consists in summing up an exposition or a chain of reasoning in some short or epigrammatic statement, that will be remembered and circulated. Such statements are adapted to cling to the mind when the whole of a diffuse explanation has vanished. ‘Property has its rights as well as its duties,’ is a good example. Something of the same effect is produced by compositions that all centre upon some one or a few distinct ideas that are repeated and impressed by every part of the illustration. Dr Chalmers has largely exemplified this mode of exposition and

persuasion; Malthus’s work on population is also a remarkable instance of the concentration of a large mass of illustration upon one idea, and the effect upon the reader is correspondingly powerful. The science of Astronomy in any exposition that does it justice has the same effect; it being the working out of the one great idea of Gravitation.

4. The mode of demeanour observed by a speaker or writer, although not relevant to the soundness of his arguments, is important in regard to the effect that they may produce upon the persons addressed. This is one of the many considerations as to acting on the feelings, which have to be set forth in a treatise on the whole art of persuasion. The chief point respecting demeanour, is to avoid the appearance of dictation or command when addressing people who are free to adopt or reject the proposals recommended to them. Dictation, with the majority of men, raises a feeling hostile to the speaker; whereas, by a respectful tone of address, by hinting and suggesting, instead of commanding, a prepossession is created in favour of what is urged.

5. The foregoing remark illustrates only one of a comprehensive class of requirements of persuasive address—namely, those referring to the repression of the peculiar feelings and egotistic peculiarities of the speaker, in so far as they clash with his objects. It is one of the standing weaknesses of men to be completely occupied and engrossed each one with his own feelings, and to assume that these are not incompatible with other people’s feelings or peculiarities. In the whole intercourse of life, repression of self and regard to other men’s likings are essential, but most of all in the attempts that one person makes to influence the wills of others. We are apt to assume that what impresses ourselves will impress our fellows; and it requires a cool observation of the effects that we actually produce on other men’s minds, to convince us that we are mistaken in this matter. The success of a speaker will be determined in a great measure by his ability to restrain himself, and assume the exact point of view, as well as the peculiar likings and dislikes, of his audience.

6. The known character and dispositions of a speaker have always a high influence. The respect entertained for him, the belief in the integrity and soundness of his judgments, and the affection and attachment that he is able to inspire, are well known to be conducive to the weight of his address.

7. There may be a special attempt made to induce a favourable state of mind in the hearers towards the speaker. He may expressly lay himself out to indulge their known tastes, likings, and humours, and to adapt himself to their peculiarities and habits. He may, for example, adopt a homely familiar style in addressing the uneducated, and in all cases shape his appeal so as to touch the favourite associations of whatever class he has to deal with.

8. The mere action of sympathy goes some way in every address—that is to say, there is a tendency in every man to give way to the expressed feelings of another when no obstacle stands in the way: consequently a speaker who feels and expresses his feelings intensely, has an influence through this sympathetic action, or by a sort of infection or contagion; and with an audience not indisposed to fall into the current of his emotion, he may be extremely effective. All men of naturally strong earnest emotions, coupled with the adequate power of expression or infection, have been powerful orators.

The expressed will and energetic determination of a man has always great weight in affairs, from the disposition of men to succumb to heavy pressure, when they are not sufficiently excited to resist it. It is a matter of daily observation in assemblies, that a man of strong persevering will carries a great many points that would not be conceded to a person less boisterous and troublesome: mere physical strength of voice and gesture contribute to this effect.

It is constantly seen in the world that there are men and women of naturally powerful and commanding presence, who have a far greater facility in bending the wills of those about them than other people who are equally knowing and talented. Teachers, heads of families, persons in authority, are occasionally met with having the natural gift of securing obedience from mere personal ascendancy; and the same bodily constitution has its influence in addressing multitudes. Lord Chatham was evidently an example of a man of a great natural ascendancy of character, apart altogether from the value of his ideas or the intrinsic weight of his language.

It has been found that boldness and loudness of assertion go for something with an audience, however little the assertion may be supported by evidence or proof. Loud-spoken praise on the one hand, or energetic denunciation and abuse on the other, are never altogether devoid of influence.

9. There are certain of the strong emotions of humanity that may be singled out as having great power in producing active impulses when they are once brought into play. Pity, tenderness, compassion, and the warm affections, when roused in favour of a cause, will be found to be strong auxiliaries. In like manner, the ludicrous—humour, mirth, and ridicule—have very great influence. To these we may add the passions of anger, resentment, and indignation, which may be roused, by appropriate representations of a case, to the very great damage of the person or cause against whom they are directed.

10. The gratifying of the emotions of taste and of the love of ornament and beauty, is a useful accompaniment of the persuasive art, and disposes the hearers in favour of the speaker. An ornate speaker like Burke, or a writer like Bacon, will gain influence over a class of minds by the enjoyment that each of them imparts through their style and treatment. The highest poetic art may be brought in aid of an argument; and an appeal to the taste may go a great way, as well as an appeal to the heart or the head. The author of enjoyment will always gain influence over the people that he delights, and he may use this influence to suit his other purposes.

11. There is a certain kind of persuasive address that so completely enters into the heart and feelings and entire being of an audience, that it carries them away as if by irresistible enchantment. If a speaker has the power of inspiring this overwhelming enthusiasm in the minds of an audience, he may do with them as he pleases; he works not by reason, but by infatuation. By intensely exciting and gratifying all the powerful impulses and most exquisite susceptibilities of an individual or a multitude, such an inestimable boon is conferred upon them, that the author of the enchantment may ask what he will, and it will be given him. Men will rush with eagerness to listen to a speaker or to join a cause that can inspire all their highest emotions to the utmost pitch. In our too often dull and tame existence, any system of doctrines and rites, whether religious, moral, political, or scientific, that can impart a spiritual intoxication, will command followers. Indeed an orator or leader can hardly expect to be extensively popular without some power of inspiring an enthusiasm of feeling or sentiment on the side of his cause. It is this that properly constitutes *eloquence*. A spiritual reward has to be given in return for obedience. The influence of an orator is thus of a piece with the influence of a favourite or an object of affection; an influence, not of reason, but of fascination, infatuation. When such powers of fascination concur with truth and right, they are an inestimable blessing to the world.

The progress of civilisation modifies the tone of oratory and eloquence by changing the tempers and aims of men's minds. In a rude primitive age, the passions required to be strongly roused; but in an advanced period of the world, and in calm, settled, routine, comfortable times, cautious prudence and worldly interest

exert a powerful sway, and require to be kept in view in persuasive efforts.

POETIC AND LITERARY ART.

The compositions that go under the name of poetry are so various, that a difficulty has been experienced in determining what feature is common to them all. The metrical form is evidently not the boundary of the species, as there are many compositions in prose that are felt to have a highly-poetical character, while many that are cast in a metrical dress do not deserve to be ranked in the class.

The definition given by Coleridge, if it does not completely narrow the idea of poetry to its strict limits, at least goes a great way to do so. According to him, poetry is the contrast, not of prose, but of science. Science analyzes and separates the appearances of nature into their ultimate and indivisible parts; in other words, it deals in abstractions, and in certain artificial modes of viewing the world that are adapted for explaining the order of cause and effect, or invariable conjunction therein; while poetry deals in aggregates or combinations, and endeavours to produce such combinations as are of a harmonious kind. Science deals with a majestic river by resolving it into the forces of gravitation, cohesion, liquidity, optical transparency, solubility, &c.; poetry, in common with painting, views it in its full body and entire aspect, and instead of decomposing, *combines* it with other objects of the landscape. To harmonise combinations of different objects and effects is the aim of art in every region; *to harmonise the images and thoughts that can be conveyed by language with one another, and with the language itself, is a general description of the poetic art*. But in accomplishing its end, poetry has to select appropriate subjects; for it is not everything expressible in language, however harmonious, that will constitute the matter of a true poem. Accordingly, there is a certain range of materials adapted for poetic treatment, and reproduced in the literatures of all ages: being the objects in the outer world, and the occurrences and situations of human life that most profoundly stir and agitate the minds of men. The eternal struggle of humanity with the world around, and the dread powers above; the tragedy and the triumph of human life; the alluring passion of love, and the intense aspirations of men towards the great, the lofty, and the infinite; the magnificence, the variety, the complexity, and the mystery of nature and of being; the divinities that are recognised as ruling in the sphere of the supernatural; the great aspects and scenery of the firmament above, and of the earth beneath; the revolutions of time and seasons; the mode of existence, the achievements and the vicissitudes of human societies, and of their leaders and heroic men; the great conflicts and struggles that decide the fate of nations; the exertions of the superior minds of the race to carry forward human progress and civilisation; the powerful contrasts presented in human life; and, in general, all objects that address themselves to the feelings and susceptibilities that we term sublime, awful, grand, venerable, beautiful, melodious, pathetic, stirring, humorous, or picturesque. The mere vulgar utilities of life, although indispensable to the existence of men, and therefore the objects of their solicitude, do not stir and occupy their entire being so effectually as these matters of extraneous interest, and are not included among poetic subjects. The exclusion also extends to scientific abstractions and technicalities, to tables of logarithms, calculations of annuities, and atomic weights, although expressing some of the gravest facts of creation.

No better short example of the peculiar matter of poetry, adorned with the highest felicity of treatment, could be given than in the following lines:—

‘How sweet the moonlight sleeps upon this bank!  
Here will we sit, and let the sounds of music  
Creep in our ears; soft stillness and the night  
Become the touches of sweet harmony.

Sit, Jessica; look how the floor of heaven  
Is thick inlaid with patines of bright gold;  
There's not the smallest orb which thou beholdest,  
But in his motion like an angel sings,  
Still quiring to the young-eyed cherubim.'

The metrical form of language has always been felt to be the appropriate accompaniment of a certain elevation of subject; while the prose form suits a state of mind more free and composed, as in the ordinary routine business of life. As the dance is to walking, so is the poetical measure to prose. But since the age when prose began to be a form of literary composition, and to be cultivated with artistic skill, innumerable works have been produced which have seized upon the fittest subjects of poetry, and embodied them with a dress and treatment such as to produce effects equal to the finest metrical compositions. The speeches, histories, and moral and critical works of the ancients, which, along with poetry, constituted their polite literature, are adequate to produce the same deep intense human interest that is sought in the greatest productions of poetic genius. And in modern times there are large classes of prose works that draw upon the sources of highest poetic emotion, and differ only from poems in departing from the measured stateliness of metre to adopt a freer and more varied flow of melodious expression. The whole of our romances, novels, and unvarnished plays, together with much of our history, biography, criticism, sermons, and moral disquisitions, are distinguished by the poetical, in opposition to the utilitarian or scientific aim, and endeavour to stir, cultivate, and inspire the warm susceptibilities and generous enthusiasm of humanity.

Among the many varieties of poetical composition, there are a few that are marked by wide characteristic distinctions which deserve to be specially alluded to.

*Lyric Poetry or Song.*

This is undoubtedly the most primitive of all literary compositions. The strong predominating feeling of a moment—whether love, heroic resolve, anger, exultation, courage, admiration, grief—in a mind gifted with the outpouring of song, expresses itself in fervid and lofty phrase, which thrills the ears and hearts of men, inspiring them with the like emotion. It is, however, only a very select and limited class of minds whose creativeness takes the lyric form, and they are often incapable of any of the other great poetic efforts. But if we range over the extant literature of the world, we shall find that the most exquisite effusions of song have never been wanting to any cultivated people. The Jews, Greeks, and Romans have contributed a large proportion of those that still delight our modern ears. England, Scotland, Ireland, France, Germany, Italy, Spain, have each produced lyric poets of the finest mould; and in all these countries the mass of the people, who are too rarely reached by works of genius, have had their lives cheered, enlivened, and invigorated by congenial song.

As an exquisite example of the matter of song, and of the cheering turn that it can give to our views of life, we quote the following from Goethe, as translated by Carlyle. The title is 'The Freemason':—

'The mason's ways are  
A type of Existence,  
And his persistence  
Is as the days are  
Of men in this world.  
The future hides in it  
Good hap and sorrow;  
We press still thorough—  
Naught that abides in it  
Daunting us—onward.  
And solemn before us  
Veiled the dark portal,  
Goal of all mortal:  
Stars silent rest o'er us,  
Graves under us silent.

But heard are the voices,  
Voice of the sages,  
The world and the ages;  
Choose well; your choice is  
Brief, and yet endless.

Here eyes do behold you  
In eternity's stillness;  
Here is all fulness,  
Ye brave, to reward you:  
Work, and despair not.'

*Epic Poetry.*

The epic poem or stirring narrative, with its 'beginning, middle, and end,' its regular development and appropriate conclusion, which, when recited in early times by the wandering rhapsodist, himself perhaps the composer, proved the charm of many a social hearth or assembled village, has in these latter days been transformed into the novel or romance. Sir Walter Scott, for example, has come in place of Homer; 'Don Quixote' is a modern Æneid; and for 'Paradise Lost' and 'Regained,' we have 'Zanoni' or 'Wilhelm Meister's Apprenticeship.'

Plot-interest is the life and soul of the epic, of whatever country or time. A narrative of stirring transactions, with hairbreadth 'scapes, and moving incidents by fire or flood, full of breathless interest and painful suspense, with trials and difficulties getting thicker and thicker around the path of hero and heroine, to be triumphantly and marvellously dispersed in the end—these are the magician's materials for engrossing minds young and old, and for converting sober reality into a fairyland of day-dreams. The wide variety of this species of literature, and the changes that it has undergone between Homer and Virgil, and downward through mediæval romance to the novels of the day, would require an elaborate delineation, which has been repeatedly attempted in the more lengthened works on the history of literature. The greatest and most important peculiarity in the recent course of such productions, is the endeavour to make what is exciting in plot and character coincide more and more with what is real in life; so that the readers may not have their minds preoccupied with false and deceptive notions as to the current of the world and the characters of men. As all such works deal in representations of the transactions or doings of men and women, and put the air of reality upon these as much as possible, their readers cannot help being impressed with the view of life that they set forth; and if this proves coincident with what they actually experience when they come into similar circumstances, they have been instructed and forewarned as well as delighted. To combine truth with intense human interest is the perfection of every form of literature.

The epic form of composition has been made use of by Defoe to give a knowledge of the matter-of-fact world; and by Scott, Bulwer, and others to teach history. Moreover, to point a moral has been a frequent object with novelists; and doubtless all these, as well as many other objects, will be attained with more and more success as the art improves. But being the supply of a constant craving, this form of literature must be subject to all the changes—rational and irrational—of novelty and fashion.

*The Drama.*

This mode of composition grows out of the picturesque and striking aspects of human society and life. It represents the interesting and exciting intercourse of man with man, and the outward expression and behaviour of men in trying circumstances. Dialogue is the main tissue of the composition; and the predominating interest ought to lie in the action and reaction of the personages on one another. Other points of interest are introduced in subordination to the proper dramatic encounter: there is generally some plot, as in the epic; the thought and sentiment through-

out require to be poetic and striking; the characters must be attractive and well-sustained; and the drift and moral of the piece should not shock our sentiments of truth or propriety. In order to bring out the grandest and most powerful aspects and displays of humanity, it is found that conflict, disaster, and calamity are better adapted than positions of prosperity or good fortune are for this purpose; hence tragedy is the most exciting of dramatic writings.

The pleasure derived by all nations from tragic compositions, which delight in setting forth events of direct misery and ruin, has been one of the most puzzling questions that rhetoricians have had to resolve. It seems very strange that human beings, who are so intensely repelled by any pain or suffering that approaches themselves, should crowd with eagerness to see representations of agony and irretrievable calamity, where no crime has been committed. But if we search deep enough among the fountains of human emotion, we shall find that there is a spring in our nature that leads to this paradoxical conduct, and that the love of tragedy is not the only way that it shows itself.

If we once extricate ourselves from the narrow notion, that the things commonly meant by pleasure and pain, express all that attract or repel us, we shall be so much nearer the understanding of this question. There are many things that attract, interest, engross, arrest, and fascinate the human mind, that can hardly be said to be 'pleasing,' as the word is commonly understood. There are objects and emotions that have an irresistible interest and fascination, and yet are such as to tear and agonize the human breast. The gloomy, the awful, the terrible, the mysterious, are capable of arresting and engrossing men's thoughts, without conferring any addition to their happiness. The spectacle of punishments, executions, or death agonies, takes a deep hold of the mind, and is sometimes with difficulty prevented from becoming a taste: in uncultivated minds such things are often a positive recreation. The huge car of Juggernaut crushes the bones of living men, hurried by fascination to throw themselves in its way; and we have often heard of self-destruction becoming a rage with a certain class of minds. It is superfluous to adduce any more facts to show that there is a tragic emotion in human nature, which gives an interest to things tragic, although we are possessed of other and more healthy impulses which tend to repel such objects.

If to this susceptibility to the tragic we add the multitude of other points of interest created by the genius of the poet, we shall have no difficulty in understanding the popularity of tragedy, both in the drama and in the religion of a people. There is no man living that is not occasionally arrested and enthralled by the great fact of DEATH; and the most gross and reckless of mankind have been awakened to seriousness by the presence of the Destroyer. But the interest inspired by tragic consequences is infinitely heightened, as well as made more rich and mellow, by high displays of character and conduct, by manfulness and noble bearing, by intellect and soul, and all the high qualities that are brought out in great and gifted minds engaged in a mortal struggle. Moreover, tragedy is a truth, a fact of our daily existence, which we have to learn how to encounter. Human life is partly based on the more pleasant epic result of virtue triumphant, and partly on the tragic model of disaster and ruin, which no human power can avert, and where there is nothing left to man but to act a heroic part.

Comedy is the light and mirthful form of the drama. It sets the fear of Heaven and the solemnity of life on the left hand, and enjoys all the encounters of wit and soul that are at once picturesque and exhilarating. Dialogue, both in the letter and in the spirit, is essential to true comedy; monologue or autobiography is the very antithesis of every form of the drama. The interesting and exciting flashes of address and retort, the agreeable complications of mixed interests, plots, and counterplots, misunderstanding, and side play, are

the materials of genuine comedy. Both the tragedy and the comedy, as well as the epic, require the seasoning of a love tale, which is as essential in the world of fiction as in the world we live in.

The following extract from one of the comedies of Aristophanes is an example of the genuine dramatic style, where the effect lies in the action and reaction of the characters. Bacchus had gone down to the Shades in search of a dramatic poet, and on his arrival found a dispute commencing between Æschylus and Euripides as to who should possess the tragic throne. Bacchus acts as umpire:—

*Bacchus.* Come, now, begin—dispute away; but first I give you notice

That every phrase in your discourse must be refined, avoiding  
Vulgar absurd comparisons, and awkward silly jokings.

*Euripides.* At the first outset I forbore to state my own pretensions:

Hereafter I shall mention them, when his have been refuted;  
After I shall have fairly shown how he befooled and cheated  
The rustic audience that he found, which Phrynicius bequeathed  
him:

He planted first upon the stage a figure veiled and muffled—  
An Achilles, or a Niobe, that never showed their faces;  
But kept a tragic attitude, without a word to utter.

*Bac.* No more they did; 'tis very true.

*Eu.* In the meanwhile the chorus

Strung on ten strophes right-on-end; but they remained in  
silence.

*Bac.* I liked that silence well enough: as well perhaps or better  
Than those new talking characters.

*Eu.* That's from your want of judgment,  
Believe me.

*Bac.* Why, perhaps it is—but what was his intention?

*Eu.* Why, mere conceit and insolence: to keep the people  
waiting

Till Niobe should deign to speak—to drive his drama forward.

*Bac.* Oh what a rascal!—Now I see the tricks he used to play  
me.

[*To Æschylus, who is showing signs of indignation by various contortions.*]

What makes you writhes and wince about?

*Eu.* Because he feels my censures.

Then having dragged and drawled along, halfway to the con-  
clusion,

He foliated in a dozen words of noisy, boisterous accent,  
With lofty plumes, and shaggy brows, mere bugbears of the lan-  
guage,

That no man ever heard before.

*Eu.* Alas! alas!

*Bac.* [*To Æschylus.*] Have done there.

*Eu.* He never used a simple word.

*Bac.* [*To Æschylus.*] Don't grind your teeth so strangely.

*Eu.* But bulwarks, and samanders, and hippogriffs, and gor-  
gons,

'On burnished shields embossed in brass' bloody remorseless  
phrases,  
Which nobody could understand.

*Bac.* Well, I confess, for my part,  
I used to keep awake at night with guesses and conjectures  
To think what kind of foreign bird he meant by griffin-horses.

*Eu.* A figure on the heads of ships: you goose, you must have  
seen them.

*Bac.* Well, from the likeness, I declare I took it for Eruxis.

*Eu.* So figures on the heads of ships are fit for tragic diction!

*Eu.* Well, then, thou paltry wretch, explain—what were your  
own devices?

*Eu.* Not stories about flying stags, like yours, and griffin-horses;  
Nor terms nor images derived from tapestry, Persian hangings.  
When I received the muse from you I found her puffed and  
pampered

With pompous sentences and terms—a cumbersome, huge virago.

My first attention was applied to make her look genteelly;

And bring her to a slighter shape by dint of lighter diet:

I fed her with plain household phrase, and cool familiar salad,

With watercress episode, with sentimental jelly,

With moral mince-meat; till at length I brought her into com-  
pass:

Cephalophon, who was my cook, contrived to make them relish.

I kept my plots distinct and clear, and to prevent confusion,

My leading characters rehearsed their pedigrees for prologues.

The great dramatists, both tragic and comic, are well known to all reading men; and their individual peculiarities have been again and again discussed in the repositories of literary criticism. The mystery of their appearance in galaxies at favoured periods, while other epochs are sterile and barren, will probably long continue to engage the meditations of the curious.

THE VENTING OF EMOTION.

When the mind is powerfully moved with passion or emotion, the bodily organs are indispensably engaged, along with what is considered the more peculiarly mental part of our organisation, in sustaining the current of feeling. Whatever power of expression, natural or artificial, belongs to man, is called into play when a strong stimulus stirs up his being; and the more completely the various organs and impulses are made to harmonise with each other, the more are painful impressions relieved, and the excess of joy moderated. By the sadness of the countenance the heart is made better; by the effusions of song, and the outpouring of the feelings in appropriate language, the oppressed mind finds relief. Many compositions owe their origin to this necessity of giving an outward vent to inward emotion. The poet writes an ode or a sonnet; the religious man utters a prayer; the man in general addresses his friend, or contents himself with a soliloquy, or an apostrophe to the universe in general. Exclamations, ejaculations, oaths, and such-like outpourings, are among the forms of language employed to lighten the pressure of calamity, or calm the torrent of excitement. The more highly cultivated, and the more artistic and exquisite the language at command, the more effectually does it answer this end. The poetic genius can convert an occasion of grief into a mild and soothing sorrow which does not refuse to be comforted; and in the high outbursts of joyous elation, the same genius can transform a tumultuous stream into a gentle current of luxurious and prolonged satisfaction. To give an intellectual form to emotional excitement of every kind is a great advance in refinement as well as in human happiness: and to convert the inarticulate howl of the savage into the tranquil stream of melodious numbers and touching images, is a vast stride in human civilisation. To have therefore a language and a form for expressing all the various feelings that may swell the human breast, is one of the essentials of a community. The poetic literature of each nation generally contains examples of this among its other products; and we have many exquisite specimens of the express effort of venting emotions in appropriate language, without especially addressing any other person. The sonnets of Shakspeare seem to have purely this character.

But as, in addressing fellow-beings, the expression of individual feeling is one of the leading subjects of the communication, it happens that in the drama, and in many other modes of poetical and prose composition, there are abundant examples of the embodiment of feeling, for the purpose of relieving or gratifying the individual emotions and inward longings. How immeasurable the interval between the wail of savage grief at the prospect of death, and the embodiment of the feeling in the lines of Shakspeare!—

'Ay, but to die—to go we know not where;  
To lie in cold obstruction, and to rot:  
This sensible warm motion to become  
A knoed clod; and the delighted sprit  
To bathe in fiery floods, or to reside  
In thrilling regions of thick-ribbed ice:  
To be imprisoned in the viewless winds,  
And blown with restless violence round about  
The pendent world; or to be worse than worst  
Of those that lawless and uncertain thoughts  
Imagine howling! 'Tis too horrible!  
The weariest and most loathed worldly life  
That age, ache, penury, and imprisonment  
Can lay on nature, is a paradise  
To what we fear of death.'

An expression of this character helps to raise humanity above the terrors of evil, and to conquer misery by the grandeur of intellect.

ART OF REFINED ADDRESS.

Under this, which is the concluding head of our subject, we have to allude to the forms of address employed in the refined intercourse of life for pleasing, sympathising, consoling, and otherwise gratifying the feelings of, those about us. There is a well-known art of polite address which consists in interpolating in every kind of discourse terms and associations of an agreeable character. But the prevailing idea in the practice of polite speaking is the expression of deference and compliment, together with a careful abstinence from all disparaging phraseology. It is, in fact, assumed that every person has a predominant feeling of *self*, or *amour propre*, and that the one universal mode of pleasing address consists in gratifying this feeling.

The forms of polite and deferential speech would appear to have sprung, in the first instance, from the expressions invented for testifying respect for authority and rank. Under the Eastern despotisms of the ancient world, the prostration of the subject before the ruler was carried to the most extravagant pitch, both in act and word; and many of the prevailing forms of address no doubt originated in the early despotic civilisations. But the institutions and spirit of modern chivalry, coupled with the influence of Christianity, introduced a mode of politeness that extended to human beings in general. The greater humanity of modern ages was accompanied with a more universal courtesy. The ideal of the knight and the gentleman, as pictured by Chaucer, embodies this quality in a very beautiful and touching way:—

—— 'He was wise,  
And of his port as meek as is a maid.  
He never yet no villanie ne said  
In all his life unto no manner wight:  
He was a very perfect gentle knight.'

The formal language of courtesy is in general well enough known to the cultivated classes of society; but there is, in addition to this, the far higher art of expressing special opinions and sentiments regarding individuals to themselves in a becoming way; an art demanding a degree of judgment and delicacy which is among the rarer qualities of human beings. Such an art, however, involves so much of manner and demeanour, that it is hardly a subject of pure rhetorical cultivation.

The mode of receiving and acknowledging every kind of address is deserving of study, as being by no means an obvious suggestion of sympathy, even in minds of a sympathetic turn. In a properly-respectful acknowledgment, agreement or coincidence with what is stated should be so expressed as to guard against implying that the statement was superfluous or uncalled for.

The art of consoling, cheering, and encouraging, is a still more difficult art, and one that perhaps has not reached a very high state of advancement, if we consider that one of the large and permanent professions has been devoted to this function—namely, the spiritual order, under every system of religious belief. It is doubtful whether any examples of this style of address can be produced that would compare with the great works of oratory that have been given to the world. There are certain commonplaces of consolation—such as saying, when a misfortune or failure occurs, that we have done our duty, or intended well; or that it is the lot of men to suffer. Such ideas may be more or less adorned in the statement, but, on the whole, they cannot be pronounced of a very high order of creation.

The poetic and other literatures of the world have furnished here and there valuable examples of the arts of pleasing address, sympathy, and consolation. The defect of the habitual instances furnished in poetical and romantic composition, is their being too elaborate for ordinary imitation, especially in oral address.

# PRINTING.

PRINTING is the art of producing impressions from characters or figures, movable and immovable, on paper or any other substance. There are several distinct branches of this important art—as the printing of books with movable types, the printing of engraved copper and steel plates, and the taking of impressions from stone, called lithography. Our object, in the first place, is to describe the art of printing books or sheets with movable types, generally called *letterpress printing*, and which may undoubtedly be esteemed the greatest of all human inventions.

## ORIGIN AND HISTORY.

The art of printing is of comparatively modern origin: four hundred years have not yet elapsed since the first book was issued from the press; yet we have proofs that the principles upon which it was ultimately developed existed amongst the ancient Chaldean nations. Entire and undecayed bricks of the famed city and tower of Babylon have been found stamped with various symbolical figures and hieroglyphic characters. In this, however, as in every similar relic of antiquity, the object which stamped the figures was in one block or piece, and therefore could be employed only for one distinct subject. This, though a kind of printing, was totally useless for the propagation of literature, on account both of its expensiveness and tediousness. The Chinese are the only existing people who still pursue this rude mode of printing by stamping paper with blocks of wood. The work which they intend to be printed is, in the first place, carefully written upon sheets of thin transparent paper; each of these sheets is glued, with the face downwards, upon a thin tablet of hard wood; and the engraver then, with proper instruments, cuts away the wood in all those parts on which nothing is traced; thus leaving the transcribed characters in *relief*, and ready for printing. In this way as many tablets are necessary as there are written pages. No press is used; but when the ink is laid on, and the paper carefully placed above it, a brush is passed over with the proper degree of pressure. The Chinese chronicles state that the above mode of printing was discovered in China about fifty years before the Christian era, and the art of paper-making about a century and a-half afterwards; previous to which period, all their writings were transcribed or printed in volumes of silk cut into leaves of the required dimensions. Before the discovery of wooden blocks, the Chinese, according to Davis, were in the habit of using stone blocks, on which the writing had been engraved—a process by which the ground of the paper was made black, and the letters left white. This primitive effort led to the improved invention of wooden blocks, on which the characters were cut in relief, and the effect thereby *reversed*—the paper page remaining white, and the letters being impressed in ink.

It is a somewhat curious circumstance, that amongst the first attempts at printing by means of wood-engraving (see No. 96) which can be traced to have been made in Europe, was the making of playing-cards for the amusement of Charles VI. of France. This was towards the latter end of the fourteenth century. Thereafter came prints from wood-blocks of human figures, single or in groups; one of the earliest existing specimens of which was found in a convent not far from Augsburg, with the date 1423 upon it. It is a representation of St Christopher, by an unknown artist; and is now, or was lately, in the possession of Earl Spencer. These prints were at first without any text, or letterpress, as it is modernly termed; but after the groundwork of the art had been completed, its rise towards perfection was almost unparalleled in rapidity. Its

No. 95.

professors composed historical subjects with a text or explanation subjoined. The pages were placed in pairs facing each other; and as only one side of the leaf was impressed, the blank pages came also opposite one another; which, being pasted together, gave the whole the appearance of a book printed in the modern fashion. The people not being able to read, were in this manner impressed with glimmering ideas of sacred history. Remarkable incidents mentioned in the books of Moses, in the gospels, and in the Apocalypse of St John, were thus made known to the less-instructed classes, but generally in connection with superstitious legends of the middle ages. Some works of this class were called *Biblia Pauperum*—‘Poor Men’s Books;’ and copies of them are now extremely rare. ‘The few copies which remain in existence,’ says Timperley, in his curious ‘Encyclopedia of Literary and Typographical Anecdote,’ ‘are for the most part either imperfect, or in very bad condition. This will not excite much surprise, when it is considered that it is a kind of catechism of the Bible, which was executed for the use of young persons and the common people—it being the only part of the Sacred Book at that time within the reach of the commonalty; a complete Bible in manuscript being then worth a hundred pounds of our money. These facts will account for the destruction of almost every copy of the “Biblia Pauperum,” by repeated use, and for the mutilated state of the few copies that remain. The work consists of forty leaves, of a small folio size, each leaf containing a cut in wood, with extracts and descriptive sentences referring to the subjects of the cut. Each page contains four busts—two at the top, and two lower down; together with three historical subjects.’ To those unacquainted with the estimation such ancient pieces of printing bear among the virtuosi, it may be amusing to learn that fair copies have brought upwards of £250, and the very worst rarely less than £50.

The next step in the science of typography was that of forming every letter or character of the alphabet separately, so as to be capable of rearrangement, and forming in succession the pages of a work, thereby avoiding the interminable labour of cutting new blocks of types for every page. It is exceedingly remarkable that this most important and yet simple idea should not have occurred to the Romans; and what renders it the more surprising is the fact, which we learn from Virgil, that brands, with the letters of the owner’s name, were in use in his time for the purpose of marking cattle. The credit of the discovery was reserved for a German, John Guttenberg (or Guttemberg), who accomplished this important improvement about the year 1438. As this man was the first great improver of typography, to the study of which he exclusively devoted his whole time and attention, a short sketch of his life will only be a part of the history of the art:—Guttenberg, who is supposed to have been born at Mayence, or Mentz, in the beginning of the fifteenth century, settled at Strasburg about the year 1424. In 1435 he entered into partnership with Andrew Drosenhennis (or Dritzehen), John Ruff, and Andrew Heelman, citizens of Strasburg, binding himself thereby to disclose certain important secrets connected with the art of printing, by which they would attain opulence. The workshop was in the house of Dritzehen, who, dying shortly after the work was commenced, Guttenberg immediately sent his servant, Lawrence Bieldich, to Nicholas, the brother of the deceased, and requested that no person might be admitted into the workshop, lest the secret should be discovered, and the *forms* (or fastened-together types) stolen. But they had already disappeared; and this fraud, as well as the claims of Nicholas Dritzehen to succeed to his brother’s

705

share, produced a lawsuit among the surviving partners. Five witnesses were examined; and from the evidence of Bieldich, Guttenberg's servant, it was incontrovertibly proved that Guttenberg was the first who practised the art of printing with movable types, and that, on the death of Andrew Dritzehen, he had expressly ordered the forms to be broken up, and the characters dispersed, lest any one should discover his secret. The result of this lawsuit, which occurred in 1489, was a dissolution of partnership; and Guttenberg, after having exhausted his means in the effort, proceeded, in 1445-46, to his native city of Mentz, where he resumed his typographic labours. Being ambitious of making his extraordinary invention known, and of value to himself, but being at the same time deficient in the means, he opened his mind to a wealthy goldsmith and worker in precious metals, named John Fust or Faust, the first regular printing establishment was begun, and the business of printing carried on in a style corresponding to the infancy of the art. After many smaller essays with respect to the capabilities of his press and movable types, Guttenberg had the hardihood to attempt an edition of the Bible, which he succeeded in printing complete, between the years 1450 and 1455. This celebrated Bible, which was the first important specimen of the art of printing, and which, judging from what it has led to, we should certainly esteem as the most extraordinary and praiseworthy of human productions, was executed with cut-metal types on six hundred and thirty-seven leaves; and, from copies still in existence in the Royal Libraries of Berlin and Paris, some of them appear to have been printed on vellum. The work was printed in the Latin language; and besides those on vellum, there are several copies on paper in Germany, France, and England—all of which are justly esteemed as the highest bibliographical treasures.

The execution of this—the first printed Bible—which has justly conferred undying honours on the illustrious Guttenberg, was, most unfortunately, the immediate cause of his ruin. The expenses incident to carrying on a fatiguing and elaborate process of workmanship for a period of five years, being much more considerable than what were originally contemplated by Faust, he instituted a suit against poor Guttenberg, who, in consequence of the decision against him, was obliged to pay interest, and also a part of the capital that had been advanced. This suit was followed by a dissolution of partnership; and the whole of Guttenberg's apparatus fell into the hands of John Faust, who, from being the ostensible agent in the business of printing, and from the wonder expressed by the vulgar in seeing printed sheets, soon acquired the name of a magician, or one in compact with the devil; and under this character, with the appellation of Dr Faustus, he has for ages enjoyed no very enviable notoriety.

Besides the above-mentioned Bible, some other specimens of the work of Guttenberg have been discovered to be in existence. One in particular, which is worthy of notice, was found some years ago among a bundle of old papers in the archives of Mayence. It is an almanac for the year 1457, which served as wrapper for a register of accounts that year. 'This,' says Hansard, 'would most likely be printed towards the close of 1456, and may consequently be deemed the most ancient specimen of typographic printing extant, with a certain date. That Guttenberg was a person of refined taste in the execution of his works, is sufficiently obvious. Adopting a very ancient custom, common in the written copies of the Scriptures and the missals of the church, he used a large ornamental letter at the commencement of books and chapters, finely embellished, and surrounded with a variety of figures as in a frame. The initial letter of the first psalm thus forms a beautiful specimen of the art of printing in its early progress. It is richly ornamented with foliage, flowers, a bird, and a greyhound; and is still more beautiful from being

printed in a pale blue colour, while the embellishments are red, and of a transparent appearance. What became of Guttenberg immediately after the unsuccessful termination of his lawsuit with Faust is not well known. Like the illustrious discoverer of the great Western Continent, he seems to have retired almost broken-hearted from the world, and to have spent most of the remainder of his days in obscurity. It is ascertained, however, that in the year 1465 he received an annual pension from the Elector Adolphus, but that he only enjoyed this small compensation for his extraordinary invention during three years, and died towards the end of the month of February 1468.

It long formed a subject of contention amongst antiquaries and bibliomaniacs, by what means Guttenberg formed his types; but it is now pretty clearly ascertained that they were at first all individually cut by the hand. The mode of casting types in moulds has been very generally, and seemingly correctly, assigned to Guttenberg's successor, Schoeffer. This individual was an industrious young man of inventive genius, an apprentice with Faust, who took him into partnership immediately after his rupture with Guttenberg, and who is supposed to have been initiated into the mysteries of the art by the latter. The first joint publication of Faust and Schoeffer was a beautiful edition of the Psalms, which came out only about eighteen months after their going into partnership. Along with it appeared a declaration by them, claiming the merit of inventing the cut-metal types with which it was printed; but this pretension was evidently false; and in fact it afterwards appeared that the book had been four years in the press, and must, consequently, have been chiefly executed by Guttenberg. It is worthy of notice that the above publication was the very first to which the date, printer's name, and place of publication were affixed. The most perfect copy known is that in the Imperial Library of Vienna. 'It was discovered,' says the indefatigable Timperley, 'in the year 1665, near Innspruck, in the castle of Ambras, where the Archduke Francis Sigismund had collected a prodigious quantity of manuscripts and printed books; taken for the most part from the famous library of Matthias Corvinus, king of Hungary, from whence it was transported to Vienna. The book is printed in folio, on vellum, and of such extreme variety, that not more than six or seven copies are known to be in existence, all of which, however, differ from each other in some respect. The psalter occupies one hundred and thirty-five, and the resto the hundred and thirty-sixth, and the remaining forty-one leaves are appropriated to the litany, prayers, responses, vigils, &c. The psalms are executed in larger characters than the hymns; the capital letters are cut in wood, with a degree of delicacy and boldness which are truly surprising: the largest of them—the initial letters of the psalms—which are black, red, and blue, must have passed three times through the press.'

To Schoeffer, as said before, must be justly awarded the honour of completing Guttenberg's invention, by discovering the method of casting the characters in a matrix. In an account of Schoeffer, given by Jo. Frid. Faustus of Aschaffenburg, from papers preserved in his family, we are informed that the artist privately prepared matrices for the whole alphabet, and showed the letters cast from them to his master Faust, who was so well pleased, that he gave his daughter, Christina, to him in marriage. Faust and Schoeffer concealed the new improvement, by administering an oath of secrecy to all whom they intrusted, till the year 1462, when, by the dispersion of their servants into different countries at the sacking of Mentz, by the Archbishop Adolphus, the invention was publicly divulged, and the art was spread throughout Europe. With Hansard, therefore, we may safely award to Guttenberg the high appellation of the Father of Printing; to Schoeffer that of Father of Letter-Founding; and to Faust that of the Generous Patron by whose means the wondrous discovery—the nurse and preserver of the arts and sciences—was brought so rapidly to perfection.

## PRINTING.

### EARLY PROGRESS ON THE CONTINENT.

Haerlem and Strasburg were the first places to which the art of printing was transplanted from Mentz, and this at so early a date, that each of these places has its respective advocates as being the birthplace of it. From Haerlem, it passed into Rome in 1466, where its first professors were Conrad Sweinheim and Arnold Pannartz, who introduced the present Roman type in the following year, in printing Cicero's 'Epistolæ Familiæ.' The Gothic character, from which our own *black-letter* was derived, was the next which was employed by the ancient printers; after which, in 1476, the first set of Greek characters was cast by the Italians—whether at Venice, Milan, or Florence, is a disputed point. In 1488, however, all previous attempts at the Greek character were eclipsed by a splendid edition of Homer's works, published at the last-named place, in folio, and printed by Demetrius, a native of Crete. The first book in the Hebrew character was an edition of the Pentateuch, printed in 1482; the whole Bible, including the New Testament, not being executed till 1488. This was done at Soncino, a small town in the duchy of Milan.

In 1467 printing was set up in the city of Tours; at Reuthlingen and Venice in 1469; and, it is believed, at the same time in Paris. This city was the tenth town in Europe in which a printing-press was established; it was set up by Ulrich Gering, a native of the canton of Lucerne, in the house of the Sorbonne, and in the year 1469. This Gering had been taught the art by Elias Helie von Lauffen, who introduced it into Switzerland, and he commenced the operations of the Lucerne press by publishing 'Marchesini's Biblical Lexicon Mamotretus sive Primicerius,' in the year 1470. The first work which issued from Gering's press at the Sorbonne was the 'Epistolæ Gasparini Pergamensis;' it was also published in the year 1470. Gering continued his labours until 1508, and died on the 23d of August 1510, bequeathing very considerable property for the benefit of young scholars and the poor of Paris. Strasburg was the next town which had the advantage of a press, and soon afterwards Lyons—the one in 1471, the other in 1473. In fact, so rapid at this period was the spread of the new art, that between the years 1469 and 1475, attempts at printing books had been made in most of the principal towns of Germany, Italy, France, and the Netherlands, and often, as in the case of the Spiras of Venice, with eminent success. It was introduced into Russia about the year 1560, or more than a century after its general practice in Southern Europe.

About the year 1496, the letter which we now call *Italic* was invented by Aldus Manutius, a Roman by birth, who set up the business of a printer in Venice. At first, Manutius used his *Italic*, or Venetian, as he called it, for the printing of entire volumes; but this was not generally approved of by typographers, and after a short period, *Italic* was employed only for particular words, prefaces, and introductions. Latterly, it has been the practice to use *Italic* only in very particular cases, as its constant requisition indicates a poor style of literary composition.

### PRINTING IN BRITAIN.

The early history of printing in England is obscure. The credit of introducing the art into that country was long believed to be due to Mr William Caxton, a mercer and citizen of London, who, during his travels abroad, and his residences for many years in Holland, Flanders, and Germany, had thoroughly informed himself of the process, and upon his return was induced, by the encouragement of many men of wealth and rank, to set up a press in Westminster Abbey about the year 1471. Such was the tradition amongst writers, and it is still generally believed. Its groundlessness was ascertained about the time of the Restoration, when a little book, which previously had been little thought of, fell under the notice of the curious, as

bearing date at Oxford in the year 1468, being three years antecedent to the presumed commencement of Caxton's labours. This book, copies of which are yet extant, is a small quarto of forty-one leaves, entitled 'Expositio Sancti Jeronimi in Symbolum Apostolorum ad Papum Laurentium.' At the same time (1664) a work was published by a Mr Atkins of London, entitled 'Original and Growth of Printing in England;' in which an account is given of an ancient chronicle, said to have been found in the archbishop's palace at Lambeth, containing the particulars attending the first introduction of the art. By the latter, it would appear that it took place during the reign of Henry VI., under the auspices of Thomas Bourchiers, Archbishop of Canterbury, who sent R. Tournour, master of the robes, and William Caxton, merchant, to Haerlem, who persuaded an under workman, named Corsellis, to come to England and set up a press at Oxford. The manuscript mentions that the transaction cost King Henry 1500 merks. But a single press was soon found insufficient for England; upon which the king set up another at St Alban's, and a third at Westminster; the last being placed under the charge of William Caxton, in the year 1471.

It would be useless for us here to enter into the merits of the question concerning the authenticity of the above-mentioned chronicle, which at one time divided the literary world to a violent degree. We shall only observe that the result of the disputation appears to be this:—The existence of the book before-named establishes beyond a doubt that books were printed at Oxford by Corsellis several years before Caxton set his press to work at Westminster, and therefore that that city has the honour of having been the first seat of the art in England; but Caxton was the first who introduced the printing with *moulded metal types*, the works by his predecessor having been executed merely with wooden ones. It is by our early writers not having attended sufficiently to this line of demarcation between the two stages of the art that the misunderstanding has, as far as we can judge, after much careful investigation, solely arisen.

After the art of printing had been thus introduced into Oxford and St Alban's, it spread to Westminster, Cambridge, Tavistock, Worcester, Canterbury, Ipswich, &c. in almost all cases by the encouragement of the churchmen of these places, and generally with the view of printing works of piety. About the year 1500, or probably somewhat earlier, Pynson was, by patent of Henry VII., invested with the office of king's printer, which may be regarded as the first instance of an appointment of this nature. At the close of the fifteenth and the commencement of the sixteenth century, London possessed a number of printers, but none whose name has been so celebrated as that of Wynken de Worde, a foreigner, who had been instructed under Caxton. He improved the art considerably, and was the first printer in England who introduced the Roman letter—all previous printing, and much of a later date, being in the black or German letter.

Although at first countenanced by the clergy, the art of printing was soon looked upon with extreme jealousy by the church, which at length discovered that this invention was but too certainly calculated to revolutionise the whole fabric of society. The earliest efforts of the art, as we have seen, were directed to the multiplication of the Bible; but for a period of sixty or seventy years from the date of the invention, all the copies of the Scriptures which were printed were in the Latin or some other classic language, not understood by the people. But now a new era commenced. Certain printers began to issue the Bible in the English tongue, translated from the original, and this gave mighty offence to the church, or Romish hierarchy.

In 1526 Richard Grafton, a gentleman of liberal education, having adopted the profession of printing, issued an edition of the New Testament in the English language, which drew down the wrath of the then Bishop of London. A proclamation was issued by this

prelate prohibiting its use. 'Understanding,' says this document, 'that many children of iniquitie, maintayners of Luther's sect, blynded through extreame wickedness, wandring from the way of truth, and the Catholicke fayth, craftely have translated the New Testament into our English tongue, entermedyng therewith many hereticall articles and erroneous opinions, pernicious and offensive, seducing the simple people,' &c. The proclamation goes on to order all copies of the said New Testament to be brought to the bishop's vicar-general to be burnt, under pain of excommunication, and incurring the suspicion of heresy. It does not appear that the fulminations of the bishop were of much effect. The New Testament having been readily purchased, it led to the publication, in 1535, of the whole Bible in the English language, into which it was translated by Miles Coverdale. But this noble undertaking was accomplished abroad. In 1539 England had the honour of producing an edition of the Bible in the English tongue, under the auspices of Cranmer and Henry VIII., the work being executed by Grafton and Edward Whitechurch.

The progress of the art in England, after its first rush into notoriety, was remarkably slow. In the sixteenth century it was interrupted by the broils consequent on the Reformation, and in the seventeenth century by the still greater harassments of the Civil War, and the gloomy religious spirit which prevailed up till the Restoration. This last event was even unfavourable to it, by introducing a general licentiousness and contempt for any solid and respectable literature. At this period there was an act of parliament still in force, preventing more than twenty printers to practise their art in the kingdom. 'At the fire of London in 1666 (we quote a writer in the 'Penny Magazine') the booksellers dwelling about St Paul's lost an immense stock of books in quires, amounting, according to Evelyn, to £200,000, which they were accustomed to stow in the vaults in the metropolitan cathedral and of other neighbouring churches. At that time the people were beginning to rush again, and to think; and as new capital naturally resorted in to replace the consumed stock of books, there was considerable activity once more in printing. The laws regulating the number of printers soon after fell into disuse, as they had long fallen into contempt. We have before us a catalogue (the first compiled in this country) of "all the books printed in England since the dreadful fire, 1666, to the end of Trinity term, 1680," which catalogue is continued to 1685, year by year. A great many—we may fairly say one half—of these books are single sermons, curious pamphlet sheets, and tracts.

The whole number of books printed during the fourteen years from 1666 to 1680, we ascertain, by counting, was 3550, of which 947 were divinity, 420 law, and 153 physic—so that two-fifths of the whole were professional books; 397 were school-books; and 253 on subjects of geography and navigation, including maps. Taking the average of these fourteen years, the total number of works produced yearly was 253; but deducting the reprints, pamphlets, single sermons, and maps, we may fairly assume that the yearly average of new books was much under 100. Of the number of copies constituting an edition, we have no record; we apprehend it must have been small, for the price of a book, as far as we can ascertain it, was considerable.

Roger North, speaking of those booksellers of his day who had the knack of getting up volumes on temporary matters, says, "They crack their brains to find out selling subjects, and keep hirelings in garrets, on hard meat, to write and correct by the grate; so puff up an octavo to a sufficient thickness, and there is *six shillings* current for an hour and a-half's reading." In a catalogue, with prices, printed twenty-two years after the one we have just noticed, we find that the ordinary cost of an octavo was *five shillings*.

After the Revolution of 1688, the business of printing rapidly increased, by the demands for sheets of intelligence or news, as well as for a better class of literary

productions. In the reign of Queen Anne, printing was increased still further by the issue of the 'Guardian,' 'Spectator,' and other literary sheets; and in 1731 it received considerable impetus by the establishment of the 'Gentleman's Magazine,' being the first of the class of larger periodicals. Between 1700 and 1756, about 6000 volumes (exclusive of tracts and pamphlets) were published—a number which, since the commencement of the present century, has been increased thirtyfold. According to the last census, upwards of 16,000 persons are employed in the book trade of the United Kingdom!

Printing was introduced into Scotland, and begun in Edinburgh, about thirty years after Caxton had brought it into England. Mr Watson, in his 'History of Printing,' says that the art was introduced in Scotland from the Low Countries by the priests who fled thither from the persecutions at home. Be this as it may, we find James IV. granting a patent in 1507 to Walter Chapman, a merchant of Edinburgh, and Andrew Mollar, a workman, to establish a press in that city. According to bibliographers, the most ancient specimen of printing in Scotland extant is a collection entitled the *Porteus of Nobleness*, Edinburgh. In 1509, a *Breviary of the Church of Aberdeen* was printed at Edinburgh; and a second part in the following year. Very few works, however, appear to have issued from the Scottish press for the next thirty years; but from 1541, the date from which we find James V. granting licences to print, the art has been pursued with success in the metropolis. At present, and from the beginning of the present century, it is perhaps the most distinguished craft in the city, being conducted in all its departments of typefounding, printing, publishing, and, we may add, paper-making at the mills in the vicinity.

Printing was not known in Ireland till about the year 1551, when a book in black-letter was issued from a press in Dublin; but till the year 1700, very little printing was executed in Ireland, and even since that period, the country has acquired no celebrity whatever in this department of the arts, although possessing some respectable printing establishments. At present, Dublin and Belfast are the only printing and publishing stations in the sister kingdom.

#### PROGRESS ON THE CONTINENT AND IN AMERICA.

The progress of printing on the continent of Europe has been remarkably slow. Unless in the free states of Germany, where the art is pursued to an incalculable extent, the profession of the printer is almost everywhere under the severest restrictions, and little can be published without coming first under the scrutiny of censors appointed by the governments. The art is carried on in Brussels and Paris perhaps with a greater degree of freedom than usual in other continental capitals, and from the presses in the latter city some exceedingly elegant works have been issued. But at Paris, as everywhere else, there is a general inferiority in the mechanism of the printing-office, when compared with that now in use in England and Scotland, except in those cases in which the presses employed have been imported from Great Britain.

While the art of printing has been, by slow degrees, creeping through the despotically-governed states of Europe, and establishing itself at isolated spots in Oriental countries, everywhere creating distrust, and nowhere allowed to be exercised with perfect freedom, it has readily taken root and flourished among the civilised inhabitants of North America. The first printing-press established in the American colonies was one set up at Cambridge, in Massachusetts, in the year 1638, the era of the foundation of Harvard College of that place. It was only established by the exertions and joint contributions of different individuals in Europe and America; and there is no doubt that the mechanism and types were imported from England. The first work which issued from this press was the 'Freeman's Call,' and the second the 'Almanac for New England,' both in 1639; the first book printed was the New England version of the Psalms, an octavo

PRINTING.

volume of 300 pages. In 1676 books began to be printed at Boston; in 1686 printing became known in Philadelphia; and in 1693 in New York. In the year 1700 there were only four printing-presses in the colonies. Since that period, and especially since the revolution, which removed everything like a censorship of the press, the number of printing-presses has greatly increased. The mechanism of the press has likewise been much improved in that country; and the Americans have copied the patent steam-press of Cowper of London, and now possess machines of this description. In 1800 the number of presses had increased to 300; in 1830 they amounted to 1200; and we learn that they are still increasing in number and extending their influence. Boston, New York, and Philadelphia may be considered as the principal printing stations in the Union—from the presses of which have issued not only reprints of the majority of standard English works, but original volumes and series of volumes which do honour to American literature. In their style of typography and bookmaking the Americans are still inferior to the English, sacrificing beauty and durability to economy and despatch. Some years ago, the Cherokees, one of the tribes of native Indians, set up a press, and commenced a newspaper—a circumstance which may be regarded as an extraordinary proof of the growth of knowledge in America.

We shall now proceed to a description of the art in its various branches, though without entering into the more minute, and what would be tiresome, technical details of the profession.

OF THE TYPES.

Printers in early times made the letters which they used, but in process of time the necessity for a division of labour created the distinct trade of a manufacturer of types, and it is only in rare instances in the present day that printers supply their own letter. The preparation of types requires much delicacy and skill. The first step in the process is the cutting of a punch or die, resembling the required letter. The punch is of hardened steel, with the figure of the letter cut, the reverse way, upon its point. On this die being finished, it is struck into a piece of copper, about an inch and a-quarter long, one-eighth of an inch deep, and of a width proportionate to the size of the type to be cast. This copper, being so impressed with the representation of the letter, is called the matrix. The matrix is now fixed into a small instrument or frame, called the mould, which is composed of two parts. The external surface is of wood, the internal of steel. At the top is a shelving orifice, into which the metal is poured. The space within is of the size of the required body of the letter, and is made exceedingly true. The melted metal, being poured into this space, sinks down to the bottom into the matrix, and instantly cooling, the mould is made to open with the instantaneous movement of a spring, and the type is cast out by the workman. This process of casting types is executed with great celerity. Of course every separate letter in the alphabet, every figure, point, or mark, must have its own punch and matrix. In casting types, the founder stands at a table, and has beside him a small furnace and pot with heated metal, which he lifts with a small ladle. Type metal is a compound of lead and regulus of antimony, the latter giving hardness and sharpness of edge to the composition. The proper proportions of these metals is regulated by the size of the type, a greater quantity of antimony being employed for small than large letters.

When the type is cast from the mould, it is in a rough state, and as soon as a heap has accumulated on the caster's table, they are removed by a boy, who breaks off the superfluous tag of metal hanging at the end of each type. From the breaking-off boy the types are removed to another place, where a boy is constantly engaged in rubbing or smoothing their edges upon a stone. Being now tolerably well cleaned, they are next removed to a table, and set up in long lines upon

a frame, where they are polished and made ready for use. Whatever be the size of the types, they are all made of a uniform height, and must be perfectly true in their angles, otherwise it would be quite impossible to lock them together. A single irregular type would most likely derange a whole page. The height of a type is, or ought to be, exactly one inch; but founders, much to their discredit, do not act with uniformity in this particular, the letters of some founders being higher than those of others. But all the types of one class of any founder are always uniform in size and height; and to preserve their individuality, all the letters, points, &c. belonging to one class, are distinguished by one or more notches or nicks on the body of the type, which notches range evenly when the types are set. These nicks, as we shall immediately see, are also exceedingly useful in guiding the hand of the compositor. Types are likewise all equally grooved in the bottom, to make them stand steadily.

The varieties of size of types in the present day amount to forty or fifty, enlarging, by a progressive scale, from the minutest used in printing pocket Bibles, to the largest which is seen in posting-bills on the streets. Printers have a distinct name for each size of letter, and use about twelve sizes in different descriptions of book-work; the smallest is called *Brilliant*, the next *Diamond*, and then follow, in gradation upwards, *Pearl*, *Ruby*, *Nonspareil*, *Minion*, *Brevier* (the type with which this sheet is printed), *Bourgeois*, *Long Primer*, *Small Pica*, *Pica*, and *English*. The larger sizes generally take their names thus—*Two-line Pica*, *Two-line English*, *Four*, *Six*, *Eight*, or *Ten-line Pica*, &c. Other nations have adopted different designations for their letters, principally from the names of their inventors; for instance, the French entitle *Small Pica*, *Philosophic*, from the first maker of the letter. Some of these classes of letters have derived their names from having been first employed in the printing of the prayers of the Romish Church. Thus, *Pica*, from the service of the mass, termed *Pica*, or *Pie*, from the glaring contrast between the black and white on the page; *Primer*, from *Primarius*, the book of prayers to the Virgin; *Brevier*, from *Breviary*; *Canon*, from the *canons* of the church, &c.

All kinds of types are sold by weight by the founders, the price varying in amount according to the size of the letter. The smallest size, *Brilliant*, costs about 13s. per pound; *Diamond*, about 11s. per pound; *Brevier*, from 2s. to 3s.; *English*, from 1s. 6d. to 2s.; and so on in proportion for all intermediate sizes. Expensive as types thus are, their prices will not appear too high, considering the immense outlay in cutting the punches and the general manufacture. In the *Diamond* size, 2800 go to a single pound weight of the letter i, and of the thinnest *space* about 5000.

A complete assortment of types is called a *Fount*, which may be regulated to any extent. Every type-founder has a scale showing the proportional quantity of each letter required for a fount; and a peculiar scale is required for every language. For the English language, the following is a typefounder's scale for the small letters of a fount of types of a particular size and weight:—

a	8500	h	6400	o	8000	v	1300
b	1600	i	8000	p	1700	w	2000
c	3000	j	400	q	500	x	400
d	4400	k	800	r	6200	y	2000
e	15,000	l	4000	s	8000	z	200
f	2500	m	3000	t	9000		
g	1700	n	8000	u	3400		

It will be seen from this scale that the letter *e* is used much more frequently than any other character.

Types are nowhere manufactured so well as in Great Britain, and for their elegance and regularity of form they have been much indebted to the late William Caslon, letter-founder in London. Mr Caslon was originally an engraver of ornamental devices on the barrels of firearms, and a maker of bookbinders' tools. The neatness with which he executed his work brought

him into notice, and he was appointed to cut a fount of Arabic letters for an edition of the New Testament. This occurred about the year 1720, and from this period he entered on a successful career as a letter-founder. Hitherto the types used in England had been mostly imported from Holland; but Caslon's letters, by their decided superiority over those of all competitors at home and abroad, soon put a stop to the importation of foreign types, and were held in such estimation, as to be frequently sent to continental countries. From 1720 till 1780, few books were printed in England with the types of any other than this foundry, which still continues in existence in London.

The ingenuity and success of Caslon meet with a parallel in the case of the late Mr Alexander Wilson, typesfounder in Glasgow. This person, by a strong effort of perseverance under difficulties, began to cut punches for types at his native town, St Andrews, about the year 1740, and there opened a letter-foundry—the first established in Scotland—in company with an equally enterprising individual named Bain. In 1744, Messrs Wilson and Bain removed with their foundry to the neighbourhood of Glasgow, where it long flourished. The types produced by Mr Wilson were exceedingly neat, and even elegant, and became the real foundation of the fame of the Messrs Foulis, printers, whose editions of the Classics were printed from them. Branches of the Glasgow letter-foundry were afterwards established in the English and Scottish capitals. In Edinburgh, besides the foundry of the Messrs Wilson, grandsons of the first of the name, the principal establishment of the kind is that of Messrs Millar and Company, whose types we consider as standing in the first class in respect of neatness, beauty, and regularity. They are largely employed in the printing of Bibles, newspapers, and other works in which a small type is required; and it is with letter from this extensive foundry that CHAMBERS'S JOURNAL and the present publication are executed.

The large letters used in posting and handbills are manufactured chiefly at Sheffield. In this kind of types very great improvements have also been made in recent times; and the varieties are becoming yearly more numerous and ornamental in character. The letter used in printing in North America is made principally at New York; and the style of both typography and presswork in that country is rapidly improving, and now almost competing with the products of the English press.

COMPOSING.

All the types in use in the printing-office are sorted in cases, or shallow boxes, with divisions. There are two kinds of cases—the upper and lower case; the latter lying nearest the compositor upon the frame for their support. The annexed illustration exhibits the arrangement of the cases and position of the compositor—the lower case being immediately under his hand, the upper case directly above in a slanting position, and the under part of the frame stocked with cases of different founts. In the upper case are placed all the capitals, small capitals, accented letters, a few of the points, and characters used as references to notes. In the lower case lie all the small letters, figures, the remainder of the points, and spaces to place betwixt the

words. In the lower, no alphabetical arrangement is preserved; each letter has a larger or smaller box allotted to it, according as it is more or less frequently required; and all those letters most in request are placed at the nearest convenient distance to the compositor. By this ingenious and irregular division of the lower case, much time is saved to the compositor, who requires no label to direct him to the spot where lies the particular letter he wants. To a stranger in a printing-office, nothing appears so remarkable as the rapidity with which the compositor does his work; but habit very soon leads the hand rapidly and mechanically to the letter required. When *Italic* letters have to be introduced, they are taken from a separate pair of cases of the same fount.

The process of composing and forming types into pages may now be adverted to. Placing the copy or manuscript before him on the upper case, and standing in front of the lower case, the compositor holds in his left hand what is termed a composing-stick. Sometimes this instrument is of wood, with a certain space cut in it of a particular width; but more commonly it is made of iron or brass, with a movable side, which, by means of a screw, may be regulated to any width of line. In either case, the composing-stick is made perfectly true and square. One by one the compositor lifts and puts the letters of each word and sentence, and appropriate points, into his stick, securing each with the thumb of his left hand, and placing them side by side from left to right along the line. When he places a letter in the stick, he does not require to look whether he is placing it with the face in its proper position. His object is accomplished by looking at what is called the *nick*, which must be placed outwards in his composing-stick. (See adjoining representation of a type.) This is one of those beautiful contrivances for saving labour which experience has introduced into every art, and which are as valuable for diminishing the cost of production as the more elaborate inventions of machinery. When he arrives at the end of his line, the compositor has a task to perform in which the carefulness of the workman is greatly exhibited. The first letter and the last must be at the extremities of the line: there must be no spaces left in some instances, and no crowding in others, as we see in the best manuscript. Each metal type is of a constant thickness, as far as regards that particular size of letter; though all the letters are not of the same thickness. The adjustments, therefore, to complete the line with a word, or at anyrate with a syllable, must be made by varying the thickness of the spaces between each word. A good compositor is distinguished by uniformity of spacing: he will not allow the words to be very close together in some instances, and with a large gap between them in others. His duty is to equalise the spacing as much as he possibly can; and this is in some cases very troublesome. In composing poetry, or similar matter, where there is always a blank space at one of the ends of the line, spacing is very easily accomplished by filling up the blank with larger spaces, or *quadrats*. But whether prose or poetry, the matter of each line must be equally adjusted and *justified*, so as to correspond in point of compactness with the previously set lines. The process of composing is greatly facilitated by the compositor using a thin slip of brass, called a *setting-rule*, which he places in the composing-stick when he begins, and which, on a line being completed, he pulls out and places upon the front of the line so completed, in order that the types he sets may not come in contact with the types behind them, but glide smoothly into their places to the bottom of the composing-stick.

When the workman has set up as many lines as his composing-stick will conveniently hold, he lifts them out by grasping them with the fingers of each hand, and thus taking them up as if they were a solid piece of metal. He then places the mass in an elongated board, termed a *galley*, which has a ledge on one or perhaps both sides. The facility with which some compositors can lift what is called a *handful* of movable type with-

out deranging a single letter is very remarkable. This sort of skill can only be attained by practice; and one of the severest mortifications which the printer's apprentice has to endure, is to toil for an hour in picking up about a thousand letters, and then see the fabric destroyed by his own unskilfulness, leaving him to mourn over his heap of broken type, technically denominated *pie*.

Letter by letter, and word by word, is the composing-stick filled; and by the same progression the galley is filled by the contents of successive sticks. When the compositor has set up as many lines as fill a page, he binds them tightly round with cord, and removes them from the galley. The annexed cut is a representation of a small page of types tied up, and placed on a board:—

Sometimes, as in the case of newspaper and similar work, the *handfuls* of type are accumulated till they fill the galley, and are then removed in long columns. After the matter is thus so far prepared, it is the duty of the pressman to take an impression or *first proof* from the types, in order that the compositor may correct the errors which are sure to have been made. Proofs are usually taken by means of an old large press kept for the purpose. After the galley matter is corrected, and re-corrected by the compositor, it is divided into pages of the size wanted; and head-lines, or figures indicating the number of the page, being added, the pages are arranged upon a large firm table, and there securely fixed up in an iron frame or *chess*, by means of slips of wood and wedges, or *quoins*.

This process, which is called *imposing*, being completed, and the face of the types being levelled by a *plainer* and mallet, the *form*, as it is called, is proved, and prepared for press. Proof-sheets being taken, they are subjected to the scrutiny both of a *reader* employed in this peculiar function in the office, and of the author. These having made their marks pointing out words and letters to be altered or corrected, the compositor once more goes over the form, correcting the errors by lifting out the letters with a bodkin, and, when revised, the sheet is pronounced ready for working. It may be explained that the imposing table at which all these corrections are made is usually composed of smooth stone or marble, or cast-iron on the top, and requires to be a substantial fabric.

It need scarcely be told that the size of books greatly varies; but the sizes are all reducible to a standard determined by the number of leaves into which a sheet of paper is folded. The largest size is denominated *folio*, being simply a sheet folded into two leaves or folios; and the next *quarto*, or a sheet folded, as the name implies, into four leaves. The most common size is *octavo*, each sheet of which contains eight leaves, or sixteen pages; the next is *duodecimo*, containing twelve leaves, or twenty-four pages in the sheet; and the next *octodecimo*, or eighteens, containing thirty-six pages in a sheet. There are many other sizes, such as *twenty-fours*, &c. To know how to place pages of types in a form so as to produce, when printed, a regular series upon paper, is one of the branches of the art to be acquired by the young compositor.

PROGRESSIVE IMPROVEMENTS IN TYPOGRAPHY.

The following particulars, relative to the early productions of the press, will show how the style of book-printing was gradually improved:—With respect to their forms, they were generally either large or

small folios, or at least quartos: the lesser sizes were not in use. The leaves were without running title, direction word, number of pages, or divisions into paragraphs. The character itself was a rude old Gothic mixed with Secretary, designed on purpose to imitate the handwriting of those times; the words were printed so close to one another, that it was difficult and tedious to be read, even by those who were used to manuscripts, and to this method; and often led the inattentive reader into mistakes. Their orthography was various, and often arbitrary, disregarding method. They had very frequent abbreviations, which in time grew so numerous and difficult to be understood, that there was a necessity of writing a book to teach the manner of reading them. Their periods were distinguished by no other points than the double or single one—that is, the colon and full point; but they, a little after, introduced an oblique stroke, thus /, which answered the purpose of our comma. They used no capital letter to begin a sentence, or for proper names of men or places. They left blanks for the places of titles, initial letters, and other ornaments, in order to have them supplied by the illuminators, whose ingenious art, though in vogue before, and at that time, did not long survive the masterly improvements made by the printers in this branch of their art. Those ornaments were exquisitely fine, and curiously variegated with the most beautiful colours, and even with gold and silver; the margins, likewise, were frequently charged with a variety of figures of saints, birds, beasts, monsters, flowers, &c. which had sometimes relation to the contents of the page, though often none at all. These embellishments were very costly; but for those that could not afford a great price, there were more inferior ornaments, which could be done at a much easier rate. The name of the printer, place of his residence, &c. &c. were either wholly neglected, or put at the end of the book, not without some pious ejaculation or doxology. The date was likewise omitted, or involved in some cramped circumstantial period, or else printed either at full length or by numerical letters, and sometimes partly one and partly the other—thus, one thousand CCCC and lxxiii, &c.; but all of them at the end of the book. There was no variety of characters, no intermixture of Roman and Italic; they are of later invention; but their pages were continued in a Gothic letter of the same size throughout. They printed but few copies at once, for 200 or 300 were then esteemed a large impression; though, upon the encouragement received from the learned, they increased their numbers in proportion.\*

About 1469-1470, alphabetical tables of the first words of each chapter were introduced, as a guide to the binder. Catch-words (now generally abolished) were first used at Venice by Vindeline de Spira. Early printed books had no signatures. *Signatures* are those letters of the alphabet which are put at the bottom of the right-hand pages of sheets to distinguish their order. When the alphabet is finished, a second begins A a, or 2 A, instead of a single A; and when that is terminated, A a a, or 3 A, begin the third; and so on. In order to indicate more correctly the order of each sheet, printers add figures to the initial letter on the third, fifth, and seventh pages; the numbers of these figures, which do not pass the middle of the sheet, point out the size of the edition. Thus A 2 on the third page, A 3 on the fifth, and A 4 on the seventh, show a work to be in 8vo.; in the 12mo. size, A 5 on the ninth page, and A 6 on the eleventh page, &c.; but it is now customary to give signatures only on the first and third pages of 8vo., and on the first, third, and fifth pages of 12mo.

In some modern French works, figures are substituted for letters, and the other leaves are marked by asterisks. The invention of signatures is ascribed by M. Marolles to John of Cologne, who printed at Venice in 1474; the Abbé Rive attributes it to John Koelhof, a printer at Cologne, and a contemporary with the former, from whom we have a work dated in 1472. It is, however, of little consequence who was the origi-

nator, for, on the whole, signatures are rather a clumsy expedient, merely to direct the binder in folding the sheet, and are generally much too conspicuous upon the pages.

One of the chief improvements in the style of typography has been the dismissal of abbreviations and connected letters from the founts. Formerly abbreviations were very common: the word *the* was indicated by the letter *y* and a small *e* above it; the conjunction *and* was indicated by *g*, which is a contraction of *et*. There were many of this species of abbreviations in printing both the English and Latin languages, and these were not more unseemly than the connected letters: such, for instance, as the junction of the letters *c* and *t* by a curve stroke from the top of one to the other. In recent times, all these connected letters have been disused, with the exception of *H* and *h*, because the head of the common *f* would press against the *l*, and be broke. Another very great improvement has been effected in the dismissal of the long *s*, in the case of two of this letter coming together.

STEREOTYPING.

We may now offer a brief explanation of the process of stereotyping, which has been of immense service to literature. Stereotyping is the manufacturing of fictitious, or as the word signifies *solid*, pages of types, and the invention is generally attributed to a Mr William Ged, of Edinburgh, about the year 1725. When the art was properly made known, it was hailed with acclamation by the printing and publishing world; but as experience developed its powers, it was found to be strictly applicable only to a particular kind of work.

When a page is intended to be stereotyped, the same process of putting up the types is gone through that we have already described; instead, however, of being carried to the press, the page is plastered over with liquid stucco to the thickness of about half an inch, so that a level cake is formed on the surface of the types. As soon as the stucco hardens, which it does almost immediately, the cake is separated from the types, and, on being turned up, shows a complete hollow or mould-like representation of the faces of the types, and everything else in the page. There being no longer any use for the types, they are carried off and distributed. As for the cake, it is put into an oven, and baked to a certain degree of heat and hardness, like a piece of pottery. It is next laid in a square iron pan, having a lid of the same metal, with holes at the corners. At the bottom of the pan there is a movable plate, called the *floating plate*; and upon this plate, which has a smooth accurate surface, the mould is placed with its face downwards. The lid being now placed and held tightly on by a screw, the pan, by the assistance of a crane and other mechanism, is immersed in a pot of molten type-metal—a composition of lead, antimony, and block tin—and being allowed to fill by means of the holes, it is at length taken out and put aside to cool. On opening the pan, a curious appearance is presented. The metal has run into the mould side of the cake, and formed a thin plate all over, exhibiting the perfect appearance of the faces of the types on which the stucco was plastered. Thus is procured a plate, or fictitious page of types, not thicker than the sixth of an inch. When the plate comes out of the pan, it is in a somewhat rude state, and has to be carefully pruned at the edges, its little specks picked clean, and, if necessary, one or more bad letters cut out, and replaced by soldering in the heads of movable types. The plate is also planed upon the back, in order to reduce all the plates of a sheet to one uniform thickness, by means of an ingenious rotatory cutting machine upon which it is fixed.

The stereotype plates, so prepared, are next taken to the printing-office, and made ready for press. This is done by placing them upon iron or wooden blocks, so that both plate and block make up the exact height of a page of real types. They are fixed to the blocks by the aid of small metal catches at the sides, head, and foot, which catches are held fast by slips of furni-

ture properly wedged. Notwithstanding the great care taken in making the plates level, and of a uniform thickness, it is seldom that they are perfect; and to make them as accurate as possible for a fair impression, scraps of thin pasteboard or paper are placed betwixt them and the blocks at the thinnest parts. When the impression is completed, the plates are unfixed, packed up, and laid aside for future use. Now for the specific utility of stereotyping.

In all cases of common book-work, it is best to print from types to the amount of the copies required, and then distribute the types; but in most cases of books published in parts, sheets, or numbers, stereotyping becomes absolutely necessary. It is easy to perceive the reason for this. When books are published in numbers, it often happens that many more copies are sold of one number than of another; and unless the types be kept up to complete sets in the hands of the publisher, or to print copies according to the increased demand, a serious loss is sustained. The manufacture of stereotype plates is, therefore, simply a means of keeping up fictitious types to answer future demands, at an expense greatly inferior to that of keeping the actual pages standing, or of putting the types up anew.

Another important advantage of stereotyping is, that any number of sets of plates can be cast from the same types, and these plates sent to be printed in different parts of the world. Thus a work set up and stereotyped in Edinburgh, may be printed without the expense of recomposing in London, Paris, New York, or any other city to which the stereotype plates may be sent; and this without any risk of error or deviation from the original—a feature scarcely to be obtained by the use of movable types. In illustrated works this advantage is especially noticeable—casts of an expensive woodcut, for instance, being readily obtained for the use of several and simultaneous publications.

PROCESS OF PRINTING.

The duties of the compositor do not involve the process of printing. When the forms are duly prepared in the composing-room, they are carried into the press-room, where they come under the charge of the pressmen. The earliest printing-presses were exceedingly rude, and seem to have resembled the common screw press, with a contrivance for running the form under the point of pressure. This must have been not only a laborious and slow operation, but one exceedingly defective, from the difficulty of regulating the impression, and the risk of injuring the faces of the types. The defects in these original presses were at length remedied by an ingenious Dutch mechanic, Willem Jansen Blaew, who carried on the business of a mathematical instrument maker at Amsterdam. He contrived a press, in which the carriage holding the form was wound below the point of pressure, which was given by moving a handle attached to a screw hanging in a beam having

a spring, which spring caused the screw to fly back as soon as the impression was given. This species of press, which was almost entirely formed of wood, continued in general use in every country in Europe till

the beginning of the present century. With certain lever powers attached to the screw and handle, it is represented in the preceding column.

In connection with this representation of the old common press, the process of printing may be described. The form, being laid on the sole of the press (*e*), is fixed at the sides, so as to render it immovable from its position. There are two men employed: one puts ink on the form either by means of stuffed balls or by a composition roller—the other works the press. The latter lifts a blank sheet from a table at his side, and places it on what is called the *tympan* (*t*), which is composed of parchment and blanket stuff, fitted in a frame, and tightened like the top of a drum (and hence its name), and which, by means of hinges connecting it with the sole, folds down like a lid over the form. As the sheet, however, would fall off in the act of being brought down, a skeleton-like slender frame, called a *frisket* (*f*), is hinged to the upper extremity of the tympan, over which it is brought to hold on the paper. Thus the *frisket* being first folded down over the tympan, and the tympan next folded down over the form, the impression is ready to be taken. This is done by the left hand of the pressman winding the carriage below the *platen* (*p*) or pressing surface, and the impression is performed by the right hand pulling the handle attached to the screw mechanism. The carriage is then wound back, the printed sheet lifted off, and another put on the tympan, the form again inked, and so on successively. In the above engraving the press appears with the *frisket* and *tympan* sloping upwards, ready to receive the sheet, the *frisket* being sustained from falling backwards by a slip of wood depending from the ceiling. One of the greatest niceties connected with this art, is the printing of the sheet on the second side in such a manner that each page, nay, each line, shall fall exactly on the corresponding page and line on the side first printed. To produce this desirable effect, two iron points are fixed in the middle of the sides of the frame of the tympan, which make two small holes in the sheet during the first pressure. When the sheet is laid on to receive an impression from the second form, these holes are placed on the same points, so as to cause the two impressions to correspond. This is termed producing *register*; and unless good register is effected, the printing has a very indifferent appearance. Expert workmen perform these operations with surprising rapidity, though with considerable labour. Two men employed at a press take the process of pulling and inking for alternate quantities. After the forms are wrought off, they are washed in a solution of potash to remove the remains of the ink, which is of a thick oleaginous character, and then carried back to the composing-room to be distributed. This last operation is very speedily performed by the compositors.

To suit paper for printing, it is necessary to wet it some hours previous to its being used. This is done by dipping alternate quires in water, and afterwards pressing the mass with a heavy weight, or by the screw or the hydraulic press, till the whole is in an equably half-dry or damp state.

After the sheets are printed, they are hung upon poles in the printing-office to be dried—a process which is effected slowly or speedily according to the degree of heat applied. On being dried, they are individually placed between fine glazed boards, and in this condition subjected in a mass to the pressure of a powerful press. On removal, the indentations of the types are found to be levelled, and the whole sheet to be smooth and ready for the operations of the bookbinder. Latterly, a great improvement has been effected in the smoothing process, by employing the hydraulic or water-press, which gives an enormous pressure with little aid from manual labour. (See HYDRAULICS, Vol. I.)

#### INK AND INKING-ROLLERS.

Much of the beauty of good printing depends on the quality of the ink, which it requires considerable skill to manufacture. The ink used by the earliest printers

was of such excellent quality, that in many instances it remains intensely black to this day; but a long period afterwards elapsed during which very bad ink was employed. Within the present century, great improvements have taken place in the composition of printing ink, which is now produced of a good quality in London by several manufacturers; it is, however, still inferior to the finer kinds of ink used in Paris, the French having evidently surpassed the English in producing a pure and intensely-black ink which will preserve its colour. Printing ink is composed of genuine linseed oil, boiled to the consistency of a syrup, and then well mixed and ground with lampblack. The qualities desired in the composition are depth and durability of colour, and that it should be stiff without strong adhesion, and keep soft and mellow, but dry quickly after being put upon the paper. It is made of different qualities, from 1s. 6d. to 5s. and upwards per pound weight—the cheaper sorts being of an indifferent black, but working easily, and setting rapidly, while the higher-priced require both care and time in the working and drying. The colour of the work can be increased only by the quality of the ink, and the better the quality of the ink, the more time it will take the pressman to work it, and the better also may be the quality of the paper; for it is impossible to work good ink upon inferior paper. As the depth of colour depends greatly upon the degree of boiling to which the linseed oil has been subjected; and as some prefer a dead black, some a brighter black, and others a black with a little bloom on it, it is customary for parties to bring up their inks to the desired shade by the admixture of Prussian blue or indigo. In fact there is no branch of the art which has received so much attention as the inking, and, strange to say, there is none which affords more room for further improvement.

One of the greatest of recent improvements in the art of printing is in the mode of inking the forms. From the days of Guttenberg this had been done by stuffed cushions, or balls covered with skins, by which no regularity could be preserved, and no speed acquired. Earl Stanhope, when he invented his improvement on the press, attempted the plan of inking by means of rollers, but he could not discover any species of skin suitable for the purpose: all that this nobleman so anxiously desired was at length accomplished, in consequence of a chance observation of a process in the Staffordshire potteries, where rollers formed of a composition were used. A Mr Forster, employed at a bookseller's printing-office at Weybridge, was the first who applied it to letterpress printing, by spreading it in a melted state upon coarse canvas: the inventors of printing-machines soon caught the idea, and, by running the composition as a coat upon wooden cylinders, produced the perfect inking-rollers.

The composition is formed of treacle and glue, which, being heated and melted together, are poured into long iron moulds, in which the central rod has previously been inserted. The process resembles that by which moulded candles are made, the central rod being nearly in the same predicament in the one case as the wick in the other. When taken out of the mould, the roller is a cylinder of soft and elastic matter, resembling India-rubber. If required for the hand-press, it is connected with a handle after the manner of a garden roller. The ink being placed, in moderate quantity, at the back of a smooth metal table, the workman, grasping the handle, draws the roller backwards and forwards along the table, distributing a little ink equally all over its surface; and having thus diffused some ink all over the roller, he applies the same to the types, drawing it backwards and forwards over them, to make sure that all have been inked. By this plan the types are inked more equably than by the balls, and in less than half the time. As rollers formed of treacle and glue are easily injured, not particularly durable, and subject moreover to be influenced by temperature, attempts have recently been made to introduce vulcanised India-rubber and certain compounds of gutta percha, but with

what success it is yet too premature to determine. At present, the most useful rollers are those composed of glue and treacle—one part of the former to three of the latter, with the addition of about one-fourth part of Paris-white. Some persons, however, only use the simple glue and treacle, while others use a small quantity of isinglass or a few drops of sweet oil.

Within these few years a plan has been devised for moving the rollers over the forms by an apparatus attached to the press. Self-inking presses are now coming into use; the peculiar advantages of the invention being a more regular and uniform distribution of the ink, and the saving of manual labour.

IMPROVED PRINTING-PRESSES.

As already mentioned, the original printing-press, as slightly improved by Blaew, remained in general use throughout Europe till the beginning of the present century. Its defects were of such a nature, that it seems wonderful that no effort was made during so long a time to remedy them. The surface communicating the impression, or *platten*, was generally only the size of half a sheet, and so after one portion of a form was pressed, the carriage had to be still farther wound in, and the remaining portion pressed. The consequence was, that besides losing time, the impressions upon a single sheet were not always uniform—one part being perhaps harder pressed than the other.

At length, near the close of the eighteenth century, the celebrated Charles Earl of Stanhope applied his ingenious though eccentric mind to the improvement of the printing-press. His lordship's improvements did not go the length of altering the general form or construction of the press. He left the same plan to be pursued of winding the carriage below the *platten* by a handle and *rounce*, and of pulling the impression by the application of the right hand to the seat of power. What he accomplished was the constructing of the press with iron instead of wood, and that of a size sufficient to print the whole surface of a sheet, and of applying such a combined action of levers to the screw as to make the pull a great deal less laborious to the pressman; the mechanism altogether being such as to permit much more rapid and efficient working.

The *Stanhope press*, which is here represented, consists of a massive frame of iron cast in one piece. This is the body of the press, in the upper part of which a nut is fixed for the reception of the great screw, and its point operates upon the upper end of a slider fitted into a dovetail groove formed between the two vertical bars of the frame. The slider has the *platten* firmly attached to the lower end of it; and being accurately fitted between the side guides, the *platten* must rise and fall parallel to itself when the screw is turned.

The weight of the *platten* and slider is counterbalanced by a heavy weight behind the press, suspended by a lever which acts upon the slider to lift it up, and keep it always bearing against the point of the screw.

There are two projecting pieces cast with the main

frame, to support the carriage when the pull is made; to these rails are screwed, and placed exactly horizontal for the carriage to run upon, when it is carried under the press to receive the impression, or drawn out to remove the printed sheet. The carriage is moved by a rounce or handle, with leathern girths, very similar to the wooden press. Upon the axle of this handle a wheel is fixed, round which leathern belts are passed, one extending to the back of the carriage to draw it in, and two others which pass round the wheel in an opposite direction to draw it out. By this means, when the handle is turned one way, it draws out the carriage; and by reversing the motion, it is carried in. There is likewise a check strap which limits the motion of the wheel, and, consequently, the action of the carriage. The principal improvement of Earl Stanhope's press consists in the mode of giving motion to the main screw of it, which is not done simply by a lever attached to the screw, but by a second lever. The main screw has a short lever fixed on the upper end of it, and this communicates by an iron bar or link to another lever of rather shorter radius, which is fixed upon the upper end of a second spindle, and to this the handle or lever by which the press is worked is fixed. Now, when the workman pulls this handle, he turns round the spindle, and by the connection of the rod the main screw turns with it, and causes the *platten* to descend with it and produce the pressure. But it is not simply this alone, for the power of the handle is transmitted to the screw in a ratio proportioned to the effect required at the different parts of the pull; thus, at first, when the pressman takes the handle, it lies in a direction parallel to the frame, or across the press; and the short lever (being nearly perpendicular thereto) is also nearly at right angles to the connecting rod; but the lever of the screw makes a considerable angle with the rod, which therefore acts upon a shorter radius to turn the screw; because the real power exerted by any action upon a lever is not to be considered as acting with the full length of the lever between its centres, but with the distance in a perpendicular, drawn from the line in which the action is applied to the centre of the lever.

The obvious excellence of the Stanhopean improvement in gaining power for the handle, led a number of printers to apply this species of lever power to the screw of the common press, but we believe not with marked success. The improvements of Lord Stanhope were speedily followed by the attempts of other individuals in Great Britain and America to remedy the ancient defects in printing mechanism. So numerous, indeed, have these attempts been since the beginning of the present century, that it is quite out of our power to mention them in detail. With, we believe, one or two exceptions, all the modern improvers of the printing-press have confined their efforts chiefly to the process of communicating pressure to the *platten*, so as to modify labour, and procure greater rapidity of working. In these cases the screw has been generally dismissed, and power procured sometimes by the action of two or more inclined planes working against each other; in other instances by fulcrums and levers; and in others by the straightening of a joint. The latter is an exceedingly simple and beautiful form of power, and may easily be comprehended when we say that it resembles the bending and straightening of the knee-joint: when the knee of the upright bar of the press is bent, the *platten* is drawn up; and when the knee is forced by a lever into a perpendicular position, the *platten* sinks, and the pressure is communicated. This may be considered the most efficient mode of compressing the *platten* yet discovered, and it would be difficult to rival it in the properties of simplicity and rapidity of execution. Nevertheless, such is the number and variety of improved presses in the present day, that it would not be easy to decide upon which has the best claims to the notice of printers. Among those which have gained a large share of approbation may be mentioned the *Columbian press*, which is of American invention. This new press, a representation of which is

## PRINTING.

annexed, was brought to this country in 1818 by Mr George Clymer of Philadelphia, and made the object of a patent. The pressing power in this instance is procured by a long bar or handle acting upon a combination

of exceedingly powerful levers (*aaa*) above the platten; the return of the handle or levers being effected by means of counterpoises or weights (*cc*). For ease and facility of pull this press is preferred by most workmen, and certainly the powerful command which the leverage enables the workman to

exercise, is favourable to delicacy and exactness of printing—his arm feeling, as it were, through the series of levers to the very face of the types.

The various improved presses which we have noticed are, in most cases, made of at least three sizes; namely, *demj*, *royal*, and *super-royal*—that is, they are respectively able to print sheets of these sizes; and they accordingly vary in price from about £50 to £80 each. They are nearly all manufactured by the patentees in London and Edinburgh. In the present day, the old wooden press of Blaew is entirely discarded from use in printing, and it is only to be seen occasionally in an obscure corner of the printing-office, reduced to the humble character of a proof-press.

The only instance worth mentioning, in which an improved press was made of quite a new construction, was in the case of the ingenious invention of Mr John Ruthven of Edinburgh. This mechanic contrived a press in which the types stand upon a fixed frame or table, while the pressing part or platten is brought over the form by being hurred forward on wheels. On being brought over the form, a depending hook or notch at each end of the platten is caught and pulled down by the combined action of levers beneath the table, and

operated upon by the left hand of the pressman. This was an exceedingly meritorious invention, and many presses on this plan were manufactured and sold; but experience has evinced that the contrivance is only valuable when applied to small presses, not larger than foolscap size, and chiefly useful for executing jobs. Mr Ruthven makes his presses as small as quarto size; and

as they stand on a table, and can be easily wrought by any gentleman, no better press could be recommended to the notice of the amateur printer. The above cut presents a correct representation of Mr Ruthven's press, which, it will be perceived, is of an exceedingly compact and portable form.

### THE CHAPEL.

It is worth while to remark, that till the present day the phraseology used in relation to the mechanical details of the printer possesses certain traces of the early connection of the art with men of learning. A number of the technical terms, as may be seen from the descriptions we have given, are a corruption of Latin or words. We may instance *sympan*, from *tympanum*, a drum, and *stet* (let it stand), which is used as a mark in correcting proof-sheets. The name *brevier*, applied to a certain size of type, originated, as has been already mentioned, in that letter being first used in printing the Breviaries of the Romish Church. An exceedingly old practice prevails among printers of calling their office a *Chapel*, and under this title the compositors, pressmen, and all others engaged in the office, have been in the habit of meeting together, and forming a species of lodge, in order to settle affairs connected with the internal arrangements of the office, or any disputes which may occur among members. The general improvement in everything connected with printing establishments, and the advance of manners, have greatly modified the spirit which used to prevail in these confederacies; nevertheless, the appellation of *the chapel* remains, and is of traditional interest. It has been supposed by many writers that the title of Chapel originated in Caxton's exercising the profession of a printer in one of the chapels in Westminster Abbey; and it is exceedingly probable that it has an origin of this nature, for printing was at first carried on in many places in England in connection with religious houses. Hence in M'Creery's poem, entitled 'The Press,' the author has the following lines:—

'Oh, Albion! still thy gratitude confess  
To Caxton, founder of the British Press:  
Since first thy mountains rose, and rivers flowed,  
Who on thine isles so rich a boon bestowed?  
Yet stands the chapel in yon Gothic shrine  
Where wrought the father of our English line.  
Our art was hailed from kingdoms far abroad,  
And cherished in the hallowed house of God;  
From which we learn the homage it received,  
And how our sires its heavenly birth believed.  
Each printer hence, how'er unbless his walls,  
E'en to this day his house a CHAPEL calls.'

### LAWS AFFECTING PRINTERS.

The proprietors and printers of newspapers, though entirely free from the oppressive censorship which prevails on the continent, are nevertheless subject to various laws, enforcing the mode of publication, the use of stamps, and payment of advertisement duties; but printers of books, or any common species of work, are practically left at liberty to carry on their business in any manner or way that seems suitable to themselves. Each printer, however, by the act 2 V., c. 12, is required to print upon the front of any sheet, if printed on one side only, or upon the first or last leaf of every book consisting of more than one leaf, his name, place of abode, and business; penalty for omission £5, and the like penalty for dispersing any such publication without the imprint. But no actions for penalties can be instituted except in the name of the Attorney or Solicitor-General for England, or the Queen's Advocate in Scotland. On the whole, the allied businesses of printing, publishing, and bookselling in Great Britain may be regarded as altogether free—that is, as subject to no restriction which impedes the circulation of whatever a man chooses to write, provided it be not libellous, treasonable, or of a grossly immoral tendency, and even then such offences can only become subjects of after prosecution. Copyright,

as a matter of property, is very justly protected for a term of years; but otherwise, since the abolition of the royal prerogative to print the authorised versions of the Bible and Book of Common Prayer, there is no preventive to the freest and fullest application of the printing press, unless perhaps the duty on paper, which acts indirectly as a check and obstruction.

#### PRINTING BY MACHINES.

After all the ingenuity of Lord Stanhope and that of his successors had been lavished on the press, still the process of printing could not be executed but with considerable fatigue, and at a rate of speed seldom greater than that of throwing off 250 impressions, or 125 complete sheets, in an hour. It must appear evident that this was a state of things quite incompatible with the advancement of knowledge, and the necessity for producing a large quantity of impressions in a short space of time, particularly as regarded newspapers. It became apparent that an entire revolution was required in the structure of the press; that the flat printing surface should be discarded, and cylinders brought into use. We have now to describe how this great modern invention, applied to printing-machines, came to be adopted:—

In 1790, Mr Nicholson, the editor of the 'Philosophical Journal,' procured a patent for certain improvements in printing, which patent embodies almost every principle since so successfully applied to printing-machines; and although he did not carry his views into practical effect, little has been left for subsequent engineers to do, but to apply, in the most judicious manner, the principles he laid down in his patent. He may therefore be justly considered as the originator of the great modern improvements in printing machinery; for with him originated the idea of taking the impressions from types by means of cylinders, and of inking the forms with rollers instead of balls, which constitute the two most essential parts of all effective modern printing-machines.

Whether Mr Nicholson's ideas were known to Mr König, a German, is now uncertain; but to him is due the distinguished merit of carrying steam-printing first into effect. Mr König, conceiving it possible to apply steam-power to produce accelerated speed with the common press, after various unavailing efforts to obtain assistance from the printers on the continent, came to England. Arriving in London about 1804, he submitted his scheme to several printers there with no better success, until introduced to Mr Bensley, senior, who, attracted by Mr König's plans, entered into arrangements with him. After persevering for some time in various attempts to accelerate the speed of the common press, and at the same time render the attendance of the man who inks the types unnecessary, his exertions resulted, to use his own words, 'in discovering that they were only employing a horse to do what had been before done by a man.' He, in consequence, gave up all idea of his projected improvements of the common lever press, and turned his attention to CYLINDRICAL PRINTING.

After continued experiments for some years, a small machine was made, in which the two leading features of Nicholson's invention were embraced (the cylinders and the inking-rollers), which he exhibited to Mr Walter, proprietor of the 'Times' newspaper; and on showing what further improvements were contemplated, an agreement was entered into for the erection of two machines for printing that journal. Accordingly, on the 28th November 1814, the public were apprised that the number of the 'Times' of that date was the first ever printed by machinery, steam-propelled. At this period but few persons knew of any attempts going on for the attainment of this object; whilst among those connected with printing, it had often been talked of, but treated as chimerical.

After the utility of cylindrical printing had been thus proved, it was thought highly desirable that the principle should be applied to printing fine bookwork,

where accurate register is indispensable. This was, to a certain extent, attained by using two large cylinders, the sheet of paper being conveyed from the bottom of the first cylinder (where it had received the first impression) by means of tapes, leading in a diagonal direction to the top of the second cylinder, round which the sheet was carried till the second side was printed. The first machine of this description was erected at Mr Bensley's office, where it continued at work for some years, till more modern machines superseded it.

So sanguine were the patentees (Mr König, Mr Bensley, and Mr R. Taylor) that no further improvement could be effected, that in March 1817 they issued a prospectus, offering three kinds of machines at high prices, and requiring a considerable annual premium; but we believe these offers were not embraced.

In the course of 1818, Mr Napier and Messrs Applegath and Cowper took out patents for improvements in cylindrical printing machinery. Mr Napier's invention consisted principally in using grippers instead of tapes, as in König's, for seizing hold of and leading the sheet of paper round the cylinders. Ingeniously as this machine was constructed, the principles upon which it worked caused it to give way in general estimation to those of Applegath and Cowper. These mechanics' patent, which expired in 1832, referred principally to the application of two drums placed betwixt the cylinders to insure accuracy in the register, over and under which the sheet was conveyed in its progress from one cylinder to the other, instead of being carried, as in König's machine, in a straight line from the one cylinder to the other; and the mode of distributing the ink upon tables instead of rollers—two principles which have secured to machines of this construction a decided preference for fine work. Machines of this construction were made by Applegath and Cowper for the principal printing establishments in London, Paris, Edinburgh, and many other cities; and it is nearly upon the model of their machines that other manufacturers now construct their steam-presses for the execution of ordinary bookwork.

Printing-machines are now made of various kinds, adapted to the peculiar descriptions of work for which they are required. These descriptions of work may be classed under two distinct heads: namely, the printing of newspapers, one side at a time, and the printing of a better kind of sheets, or bookwork, both sides at a time. There can be nothing more easy than to make a machine capable of first printing one side of a sheet of paper, and afterwards the second, by the removal of one form, and the introduction of another; but this process will not produce register: the second side may or may not be on the back of the first, and the work is therefore of a very inferior appearance, though suitable enough for newspapers, in the working of which despatch is chiefly required. This kind of press is therefore the best adapted to gain that end; for the first side of the paper may be printed deliberately, and the second side be made up to the last moment of time, and then thrown off. To produce a machine to print both sides at a time, and with perfect register, no small degree of mathematical accuracy, and no small share of ingenuity in the mechanician, are required. The great and important object to be attained in this kind of machine is to cause the sheet, after it has received its first impression, to travel along the sides of the cylinders and drums at such a rate as to meet the types of the second side at the exact point which will cause the second side to fall with perfect accuracy upon the back of the first. To accomplish this exceedingly desirable end, the cylinders and drums must revolve at precisely the same speed as the carriage underneath; and therefore any inaccuracy in the turning of the axles, the cutting of the teeth of the wheels, or any other deficiency, however slight, will produce ill-registered sheets, and create an enormous degree of vexation to the printer. With these explanatory remarks, we pass on to a notice of four different machines, calculated to produce register

and non-register sheets, under various modifications and rates of speed:—

1. A machine with one cylinder, called a single machine, generally used for printing newspapers; it throws off from 900 to 1200 an hour on one side, requiring two boys—one to lay on the paper, and another to receive it when printed.

2. A machine with two cylinders, called a double machine, but only printing from one form of types, at the rate of from 1600 to 2200 an hour, requiring two boys to lay on the sheets, and two to take them off, exclusively used for newspapers. It consists of two small cylinders, about ten inches in diameter, placed about five inches apart, and suspended from a beam at each end. A camb, or eccentric, causes the beams to vibrate, and with them the cylinders to rise and fall about one-half of an inch. The cylinders turn in opposite directions, and as the machine only prints one form at a time, that cylinder only which is turning in the same direction as the types is permitted to rest upon the form, and take the impression, so that a sheet is printed by each cylinder alternately every time the type-carriage goes backwards or forwards. Two boys feed the paper into the machine, at two drums placed about three feet above the carriage, and the sheet is led down to the cylinders by tapes, which also convey it, after being printed, to the end of the machine, where two boys receive the sheets, and lay them straight in a heap, ready to be again put through the machine when the second form is placed on the type-carriage to print the other side. There is a distinct and complete apparatus for inking the types at each end, similar in principle to that which is mentioned in the account of the book machine. Many of the largest-sized and best newspapers are printed by machines of this construction. They are generally moved by manual labour, two men turning a winch, which operates upon the mechanism and fly-wheel.

3. A machine similar to that used by the 'Times,' with four printing cylinders, requiring the attendance of eight boys, and throwing off about 4000 impressions an hour. To attempt to describe this machine without diagrams is difficult, but a general idea may be conveyed of its principle, by its being considered as two double machines placed in contact. There are four printing cylinders, about nine inches in diameter each, placed close together in pairs, but with a space of about seven inches between the centre ones, in which space there are two inking-rollers. Each pair of cylinders is secured to the ends of two strong beams by means of adjustable connecting rods; to these beams a slight vibrating motion is given by means of cambs, so as to cause the alternate cylinders to rise and fall about one-fourth of an inch. The type-carriage and inking-tables have a reciprocating motion, and the movements are so adjusted, that those two alternate cylinders shall be depressed, and press upon the types, whose motion coincides with the carriage, and of course the other two alternate cylinders are by the same means raised sufficiently to permit the types to pass free under them, till the carriage changes the direction of its motion, when the position of the cylinders is reversed, and the pair which formerly took the impression from the types are in their turn raised. Thus every time the form of types moves backwards or forwards, two sheets of paper are printed. The paper is fed into the machine over four drums, placed in pairs over each other, at a considerable height above the machine, by four boys. The sheets are led down from the drums to their respective cylinders by means of broad tapes, and by other tapes they are conducted out to the ends of the machine, where they are received by four other boys, when printed, ready to be again passed through the machine to receive the impression on the second side.

This ingenious machine has only two inking apparatuses, one situated at each end. There are three pairs of inking-rollers, one pair at each end, close to the two outer cylinders, the remaining pair being placed between the two centre cylinders. The inking-tables are about

three feet wide, and the motion of the carriage is sufficiently long to bring each table not only under its respective pair of inking-rollers, but also to enable each table alternately to ink the centre pair. Thus the form is first inked by one of the outer pairs of rollers; the first cylinder is raised; in passing under the second, an impression is given, and of course the ink is taken from the form, but it immediately becomes inked anew by the centre pair of rollers; the third cylinder is raised; the form passes to the fourth cylinder, where another impression is taken; and the motion of the form being continued a little farther, it gets again inked from the outer pair of rollers at the opposite end of the machine from whence it started. In its return, the two cylinders which had just taken the impression are raised; the other two now print in their turn, the inking process going on as before; and two sheets are again thrown off. Machines of this complex description are only used where extraordinary despatch, in the production of a large number of copies, is required. Few, besides those employed by the London daily papers, are in use. The only one in Scotland, as far as we know, is that used for printing the 'North British Advertiser,' and which was made by Morton and Son, machine-makers, Leith Walk.

4. The fourth kind of machine is called a book or perfecting machine, printing both sides of the sheet in register before it leaves the machine. The machine from which the annexed engraving is taken is one of this description, and bears a resemblance to that of Applegath and Cowper. It is about fifteen feet long by

five broad, and consists of a very strong cast-iron framework, secured together by two ends and several cross bars. To this frame all parts of the machine are fixed. In external figure, as seen in the cut, it is a large apparatus, of imposing appearance. On approaching it when at work, we perceive two cylinders, as large as hogsheads, revolving on upright supports; two smaller cylinders or drums revolving above them; and beneath, within the framework, a table on which lie the types at both ends, going constantly backward and forward. A belt from a steam-engine, acting upon a shaft in the frame, gives motion to the whole apparatus. It will further be observed that a boy, marked *a* in the cut, is standing on the top of some steps feeding in sheets of paper, each of which, on being delivered, is swept round the first cylinder *b* (being held on by tapes), gets its impression below from the types, is carried over and betwixt the drums above, and then brought round on the second cylinder *c*; now it gets its second side printed, and issuing into the space between the cylinders, is seized by the boy *d*, who lays it on a table completely printed. The whole operation is accompanied with a loud noise, from the revolving of the cylinders, the working of the notched wheels, and the driving of the table to and fro by a rack beneath, but without any strain on the mechanism, or risk of injury to the attendants. On minutely examining the parts, we observe that at each end there is an apparatus of rollers taking ink from a ductor or reservoir of that material, and placing it upon a portion of the moving table beneath; here other rollers distribute it, while others take it off and roll it upon the pages of types, ready for each impression.

The two printing cylinders are nearly nine feet in circumference each, and are placed about two feet apart. They are accurately turned, so that the surfaces of the type-carriages and the cylinders may be perfectly parallel. The axis of each cylinder works in brass bearings in the upright framework, where, by means of screws, the degree of pressure with which the cylinders are allowed to rest upon the types may be regulated to any degree of nicety. Over about two feet of the circumference of each cylinder which forms the printing surface, two folds of cloth, called blankets, are stretched by means of rollers placed inside the cylinder. The lower blanket is seldom changed, but the upper one, on the second cylinder (which stands in the stead of what are called slip-sheets in hand-press printing), must be shifted as soon as the ink which it has absorbed from the printing on the first side of the sheet begins to set off, or soil the paper when receiving the second impression. This shifting is speedily effected, by unrolling a sufficient quantity of the cloth off one roller, and winding it up on the other, to present a clean portion to the printing surface.

The cylinders have a continuous rotatory motion towards each other, given by two large toothed wheels, whilst the type-carriages move backwards and forwards under them. The movements are so contrived that the type-carriages shall have gone and returned to the same point during the period that the cylinders have made one entire revolution; consequently, each successive impression is taken from the types by the same part of each cylinder; and thus, in order to bring the impression level, the same facility for patching or overlaying is afforded as at the hand-press. The two drums placed between the cylinders are for the purpose of causing the sheet of paper to pass smoothly and accurately from one printing cylinder to the other.

To preserve the sheet in its proper place on the cylinders, and carry it forward through the different parts of its journey from the hand of the one boy to that of the other, there is an extensive apparatus of tapes, some of which are observable in the cut. These tapes are half an inch broad, and are formed into series of endless bands, arranged at certain distances apart, so as to fall into the interstices and margins of the forms, and therefore escape being crushed between the types and cylinders. The machine may be stopped at any instant by turning the handle of a lever, which shifts the belt from the fast to a loose pulley, without stopping the engine.

To produce an impression with a flat surface from a large form, requires a force of about from forty to fifty tons; and even with a cylinder, where a line only is impressed at a time, the pressure is little short of a ton. But, in the machine, to prevent any undue pressure of the cylinders upon the forms, there are wooden bearers, of the same height as the types, screwed upon the sides of the carriages under the ends of the cylinders; thus effectually shielding the types from the enormous and injurious pressure which a cylinder might, through accident or otherwise, be caused to exert.

Seven machines such as has been described are constantly employed printing the works of Messrs Chambers at Edinburgh, the whole, together with three flat-pressure machines, and two self-inkers, being moved by a steam-engine of twelve-horse power. At the large printing establishment of Messrs Clowes and Son in London, we believe at least twenty machines of this kind are to be seen daily at work.

Besides those various descriptions of machines above alluded to as being principally in use, there are others calculated to execute work of a more peculiar nature. Perhaps the most wonderful of those ingenious pieces of mechanism is a machine which has been made to print two colours by only one impression—a lower form charged with one colour being caused to rise through and come upon a level with another form, so that both may be printed at once. Hitherto the work which has been executed by this machine has consisted chiefly of

the stamp-duty marks for the Excise, and for bank-notes, fancy labels for druggists, and other similar jobs.

A machine for printing newspapers (on one side at a time) has also come into use, constructed by Carr and Smith of Belper, on the plan of an advancing and retreating cylinder, while the table for the types is stationary. It is more easily turned than the other kinds of newspaper machines, and is said to be exceedingly suitable for printing newspapers of a limited number of impressions, such as are issued in many country towns.

Another cylinder machine which we may here notice is one invented by Mr Cowper, intended to print from convex stereotype plates. The plates, instead of being fixed flat upon blocks, as will shortly be described, are fastened upon the cylinders, so as to give them a bent form, and the printing is effected with the face of the plate or type-surface downwards; whereas the paper is placed underneath instead of uppermost, as in all other printing. We have never heard what are the peculiar advantages of this fanciful contrivance.

Among recent inventions of this kind may also be noticed Hill's patent printing-press, by which it is said from 1200 to 1500 impressions per hour can be worked off with less labour and exertion than are required by the common hand-press to work off 300 impressions. This machine is on the cylinder principle; the supply and distribution of ink are effected by the table and types running under the rollers in the ordinary manner, and the chief novelties in construction consist—*first*, in the arrangement for moving the type table; and *second*, in the apparatus for taking off the sheets when printed. When the machine is small, motion is given by means of a treadle, which the pressman works with his foot, whilst his hands are employed in laying on the sheets; in presses of larger dimensions hand-wheels may be used; and in establishments where steam-power is employed, any number of these presses may be driven by an overhead shaft. The manner in which impressions are taken is as follows:—The form of types being fixed and made ready for printing, and motion being given to the wheel, the pressman connects the motion of the wheel to the axis of the printing cylinder by a sliding clutch; he then lays a sheet on the register-plate, with its front edge and one of its ends in contact with a guide, and on the printing cylinder arriving at a certain position of its revolution, the front edge of the sheet is secured to the cylinder by claws, which carry it round to meet the types and receive the impression. By the time the impression is completed, the cylinder has brought the front edge of the sheet within the claws of the removing-arm, which claws then close and secure the sheet; and simultaneously beneath, the cylinder claws open, and allow the sheet to pass from the cylinder by the removing claws, and to be deposited on a shelf ready for being removed by hand. On the end of the cylinder spindle outside the frame there is a crank-iron, which pushes back the type-table after an impression has been taken; and on its arriving at its most backward position, the crank-arm quits its connection with the table, and a connection takes place between the end of the printing cylinder and the edge of the type-table, by which means a firm contact takes place between the two surfaces, which produces the forward motion of the tables and types to produce the impression. In both of these respects the simplicity of construction and working efficiency of the machine are such as apparently to leave nothing more in the shape of improvement to be desired.

#### Extra-fast Machines.

Astonishing as the powers of any of the above machines may appear, they are infantile in comparison with what has been exhibited by more recent inventions. Among these inventions—successful and partially successful—we may point to those of Messrs Little and Applegath:—To explain the advantages of Mr Little's *Double-Action Machine*, it must be remembered that by the 'Fast Machine,' such as is used for printing the daily newspapers, the impression is obtained by

four cylinders, two of which revolve constantly in one direction, and the remaining two constantly in an opposite direction: thus only two sheets of paper can receive an impression from the "form" of type with each passage of the table—the cylinders, when giving the impression, necessarily travelling in the same direction as the table; hence although the form passes under the four cylinders, two of these are alternately idle, and the machine consequently produces only two printed sheets with every backward and forward motion of the type.

'The Double-Action Machine'—we abridge from the *Mechanics' Magazine*—works with *eight cylinders*, six of which have a reversing motion, and it produces seven printed sheets with every transverse motion of the type. Thus in the "Fast Machine," only half the cylinders actually print alternately, whilst in the latter, seven out of eight of the cylinders are constantly at work; so that, supposing both machines to have the same number of cylinders, the Double-Action Machine would, from this circumstance alone, produce nearly twice the quantity of printed sheets; but on comparison it will be seen that considerably more than twice the number can be produced.

The surface of the type, it is known, rests on a horizontal table, which is moved backward and forward by a pinion working in a rack beneath the table. This rack, terminating at each end in a semicircle of a certain diameter, has consequently, besides its traversing motion, a lateral motion, at the time of which the progress of the table may be considered as neutral, or, in other words, the operation of printing is at a "standstill" until the pinion has passed round the end of the rack, causing a considerable loss of time during several thousand revolutions. Thus to print *twenty thousand* sheets by the present Fast Machine, the pinion must pass *five thousand times* round each end of the rack, which, with a rack of six inches diameter, is equal to a space of 15,000 feet. To print *twenty thousand* sheets by the Double-Action Machine, it is evident that, as seven sheets are produced from each passage of the table, the pinion will have to pass round each end of the rack only *fourteen hundred and twenty-eight* times, equal to a space of 4284 feet, or 10,716 feet less than in the Fast Machine. Another source of gain in the Double-Action Machine arises from the cylinders being diminished in size, and by working them as closely together as possible, the present four-cylinder machine requiring a rack of *six feet*, whilst the Double-Action Machine, with twice the number of cylinders, requires a rack of only eight feet, which, multiplied into the number of revolutions required to work *twenty thousand* copies, is about equal to 5712 feet.

It has been stated that the Double-Action Machine has eight cylinders, and that seven printed sheets are produced from each passage of the types. Of these eight cylinders, six only have a reversing motion, or revolve backward and forward; each of the end cylinders lifts and revolves constantly in one direction, like the cylinders of the present Fast Machine. The reason why the end cylinders differ from the other six is this: in consequence of the reversing motion of the six cylinders, it is necessary that a certain interval of time should elapse to allow the sheet in work to get clear off before the next sheet can be allowed to enter. To effect this, the table must traverse a certain distance beyond the extreme vibrating cylinder; and advantage is taken of this space to place a lifting cylinder, which does not require the type to pass beyond its centre—thus giving one sheet more from each end of the machine, amounting to 2856 during the working of 20,000 sheets. This will explain how seven sheets only are produced from eight cylinders, each of the end cylinders producing only one sheet, whilst the remaining six produce two each, from one revolution of the rack or table.

The advantages of Mr Little's machine are said to be—1. Rapidity of action, being capable of yielding 15,000 impressions an hour, with eight cylinders; 2. An improvement in the quality of printing, since the rate of

going may be diminished, and yet the numbers thrown off exceed those by the common Fast Machines; 3. More perfect register, since six out of eight cylinders are not disturbed by lifting; 4. Better inking, as the rollers, from the increased length of table, have more time for distribution; and, 5. More certain feeding of the sheets, since at each drum arrangements are made for double laying-on.

With regard to Mr Augustus Applegath's new machine which has been constructed for the 'Times,' we abridge the following notice from that paper, 29th December 1848:—'The great improvement which has now been effected by Mr Applegath, is the substitution of a uniform rotatory motion for the horizontal reciprocating motion of the old machines. It is the change from a plane to a circular "table." Instead of being laid on a table traversing a railroad, the types are now built up, as it were, on the face of a cylinder revolving on a perpendicular axis. This cylinder is a drum of cast-iron, about 5 feet 6 inches in diameter. The "forms," or pages of type, are made segments of its surface, just as a tower of brick might be faced with stone. Eight printing cylinders, forty inches in circumference, are arranged round the drum. Instead of the four impressions taken by the old machine in its double journey, eight sheets are now printed in every revolution. Any one who knows the immense weight of metal type, and the impossibility of giving it any hold upon the "form" besides weight and pressure, will at once perceive the extent of the obstacle overcome by giving the central drum a vertical position. In the vertical disposition there is the same centrifugal impulse as in the horizontal, but it does not operate in the direction of gravity, and therefore is more easily neutralised. This is done chiefly by means of the "column rules," which make the upright lines dividing the columns of the page. These "column rules" are usually long strips of brass, and in this instance they are so screwed to the sides of the iron frame, or "chase," as to become powerful tension ties; and being made with a wedge-like section—that is, thicker towards the outer surface of the type—they keep it in its place, like the keystone of an arch, or the stone ribs of a rubble vault.

Without the aid of drawings it is difficult to convey an idea of a machine so different from those on the horizontal principle. On entering a large room, the first thing that strikes the eye is a circular gallery about 25 feet in diameter, and 6 feet from the ground, surmounting eight large and complicated fabrics radiating from a central tower or drum. Each of these fabrics is the feeding apparatus attached to one of the eight printing cylinders. On the gallery are seen eight men at so many "laying-on-tables," feeding the machine, by carefully pushing successive sheets into its eight mouths, each man at about the rate of one sheet in four seconds. Directly under those men are eight others on the ground, employed in taking-off and piling the printed sheets thrown out by the machine. The eye soon detects the four forms or chases of type fixed on the face of the drum, and accommodated to its shape, and vainly attempts to follow numerous sheets of paper in rapid and inexplicable motion. The printing cylinders surrounding the central drum, and in occasional contact with it, bear about the same visible proportion to it as the pillars of the temple of Tivoli to the circular wall within. The framing which supports the central drum also carries the bearings of the eight printing cylinders, which all revolve in perfect correspondence. The type only covers a small portion of the circumference of the drum, and in the interval there is a large inking-table fixed, like the type, on its circular face. This table communicates the ink to upright inking-rollers, placed between the several printing cylinders—the rollers, in their turn, communicating the ink to the type. So far the arrangement is perfectly simple, the machine being in fact composed of the parts in ordinary use, only made circular, and placed in a vertical instead of a horizontal position.

The great problem for the inventor was the right mode of "feeding," or supplying the sheets of paper to the printing cylinders in their new position. The reader will easily understand by spreading out a sheet ("The Times newspaper"), the difficulty of changing it in less than four seconds from a horizontal to a perpendicular position, and back again; and through still more changes of direction. No alteration has been made in the manner of "laying on" the paper, which is carried from a plane table in the usual way, downwards between two sets of endless tapes in rapid motion. But when the sheet has travelled down to a certain point, it is suddenly stopped by thin pieces of wood placed edgewise, and brought into contact with the paper on both sides at once; it is at the same moment released from the tapes, and, being now at rest, is held in a vertical position between the thin pieces of wood, or "stoppers;" these stoppers are then withdrawn, and the sheet hangs for a moment suspended between two small pulleys called finger rollers; a set of vertical rollers (between the stoppers), revolving rapidly, are immediately brought into contact with the sheet, and impel it horizontally between two new sets of endless tapes, which convey it round the printing cylinders. It there meets the type, receives the impression, and is led out under the feeding-gallery into the hands of the "taker off," who draws it down and lays it on a table before him.

It now only remains to explain how an even and clear impression is obtained from a segmental surface of type. The printing or impression cylinders are 40 inches in circumference, and each cylinder always touches the type at the same corresponding points, the surfaces moving with equal velocity. The blanket or cloth round the printing cylinders is underlaid or packed out with slips of paper; and by this simple means, and the use of a type cylinder of large diameter, an impression is obtained, to use the words of the patent, "not discernible from that given by a flat form of type." The rate at which this machine has hitherto been worked is about 1000 revolutions per hour, or 8000 impressions. This rate will be gradually increased until it is ascertained how far it may be urged without injury to the impressions, and danger to the delicate and complicated fabric. The horizontal machines, with four cylinders, have been driven up to 6000; and it is probable that this machine with eight cylinders will be ultimately worked to 12,000 copies an hour.

#### Flat-Pressure Machines.

We have now described the advantages of cylinder printing, and it is but proper that we should mention certain drawbacks to its universal use. The pressure by a round or cylindrical surface is less perfect than that given by an even surface. The cylinder has the effect of pressing partly on the edge of the type, both in coming up to the impression and in leaving it; therefore the impression, in technical language, is not clean; it has a slight blurring, or wants that degree of sharpness and fairness that is required in fine bookwork. Cylinder printing, from the same cause, wears down types much more quickly than flat presses. A fully more important defect is the time required to prepare a sheet of types, or forms, for the machine. A sheet, such as the present, seldom requires less than four hours to make ready, and a sheet of stereotype plates two hours longer. The pressure of the cylinders is so searching, that the smallest defect in the levelness of the forms or of the blanket and printing surface is observable, and must be remedied by putting patches beneath the outer blanket. So much time is thus consumed in preparing a sheet for the cylinder machine, that it would be a positive loss to print anything at it, unless a very considerable number of copies were wanted. In other words, cylinder machines are only suitable for long impressions, and where a moderate fineness of work is sufficient.

These deficiencies of the cylinder machine have led to numerous and expensive attempts to apply steam-

power to machines with flat printing surfaces. The most successful of these attempts has been one by an American, and another by a gentleman in London, whose machines have been working for some years in Mr Spottiswoode's printing-office. The latter is by far the best, and is now coming into general use. It consists of an upright frame and printing platten, resembling the common hand-press, with a type-carriage at each side. The type-carriages go below the platten alternately; so that, in point of fact, the apparatus is two presses with one printing surface to serve both. The movements to and fro of the type-carriages, and the pull downwards of the platten, are effected by machinery beneath. The forms are also inked by an apparatus for the purpose. This machine requires a layer-on and taker-off of sheets at each end, besides a superintendent, and works about 700 sides per hour, or 350 complete sheets. Since the expiry of the patent,

machines of this kind have been made by J. Brown and Co., engineers, Kirkcaldy. The mechanism is very beautiful and effective, answering every purpose of bookwork in ordinary demand. Three machines of the Messrs Brown's construction are employed in the establishment from whence this sheet proceeds: the preceding illustration represents the latest and most approved form of arrangement—the type-tables travelling horizontally, as in the cylinder machines, and the platten rising and falling with undeviating accuracy at the return of each table.

By the introduction of the steam-presses which we have now described, the profession of the printer has within these few years undergone a most extraordinary revolution; and although perhaps fewer hand-pressmen are now employed than formerly, the increase of employment to compositors, engineers, bookbinders, booksellers, &c. must be very great. The principal advance in the profession has been since the year 1832, when the printing of cheap literary sheets rose into importance; and, by a fortunate coincidence, the patents of various machines having about the same time expired, a new impulse was given to the trade. Hardly a newspaper is now anywhere printed with a hand-press, and few or no periodical publications. The making of printing-machines has in itself become a great business. One maker in London some time ago mentioned to us that he produced a machine regularly every three weeks upon an average all the year round, each at a price of about £400. Other manufacturers in London, and also now in Scotland, are similarly engaged; the machines being sent not only to all parts of Europe, but to America, Australia, and India. In a few years there will not be a civilised country of any consequence on the globe which does not possess these powerful distributors of human knowledge.

It will readily be supposed that the introduction of a steam-press such as we have described has caused a very extensive alteration both in the dimensions of many printing-offices and in their organisation. Printing is now a manufacture. The printing-office is a factory; and the interior of one of these concerns usually presents a remarkable spectacle of industry, animate and inanimate, which to a stranger leaves a lasting impression on the memory.

## ENGRAVING—LITHOGRAPHY—PHOTOGRAPHY.

In the preceding sheet we endeavoured to describe the process of producing impressions from movable types, generally known as *letterpress-printing*: in the present, we direct attention to the allied, but more difficult and delicate arts of producing impressions from engravings on wood, copper, steel, and other metals, from drawings on stone, and by the action of the sun's rays on chemically-prepared substances.

### WOOD-ENGRAVING.

The method of taking impressions, or printing from woodcuts, being precisely the same as that followed in ordinary letterpress, we commence with a brief account of the art of Wood-Engraving, or, as it is sometimes more learnedly termed, from Greek and Latin compounds, Xylography and Lignography. In doing so, our aim will be to afford such information as may serve at once the purposes of the general reader, and of the individual who may be desirous of acquiring some skill in the practice of the art.

During the last twenty years, it will have been observed how great has been the increase of works containing wood-engravings, either for the purpose of illustration or embellishment. The illustrations throughout the present work belong to this species of engraving, and few publications of a cheap class are now issued without them. Usually less delicate and minute than engravings on copper or steel, woodcuts possess a peculiar value from the comparative ease with which they can be printed. While plate embellishments require to be produced by a process so tedious, that a man can with difficulty execute 250 impressions in a day, a wood-engraving can be printed with great rapidity by a machine to the extent of many thousands daily. The chief value of the woodcut, however, consists in its being adapted for printing along with letterpress. It is inserted among the types by the compositor, and impressions come from it along with the letterpress which it is intended to illustrate. Hence a woodcut is to be described as a *type*—a thing which produces

No. 96.

representations by being stamped on paper, after having been inked for the purpose. The reason why wood-engravings possess these qualities over metal plates is, because the figures or marks to be shown in print are left raised on the wood, the parts not to be printed being cut away. This is the reverse of the principle of metal-plate engraving, in which, as will hereafter be seen, the figures or marks are sunk, and hence the difficulty of effecting impressions with any degree of rapidity. Another peculiar advantage arises from the fact, that stereotype casts can be obtained from woodcuts as readily as from movable types, thus giving the printer the power to multiply them indefinitely.

The art of carving figures in relief on the face of a piece of wood, and then stamping the figures, blackened with ink, on paper, or some other light fabric, is of great antiquity. The Chinese have for ages stamped or printed books in this rude manner. In Germany, the first attempts at printing with a press were effected by wooden blocks, which, however, were soon abandoned, in consequence of the invention of printing by movable types. Previously, the subjects stamped in Germany were for the greater part of a devotional kind, such as representations of saints, for distribution by the clergy as aids in devotion. The earliest print from a woodblock of which we have any certain date is, or was lately, in the collection of Earl Spencer: it is the representation of St Christopher carrying the infant Saviour across the sea, bearing the date 1423. It was discovered in one of the most ancient convents in Germany—the Chartreuse of Buxheim, near Memmingen—pasted within one of the covers of a Latin manuscript of the year 1417. It has an inscription at the bottom, which has been thus translated:—

'In whichever day thou seeest the likeness of St Christopher,  
In that same day thou wilt, at least, from death no evil blow  
incur.—1423.'

A reduced fac-simile of this curious engraving forms the illustration at the head of the present article. Besides being employed to illustrate devotional subjects, wood-engraving was used in Germany for marking the figures on playing-cards; and, what is somewhat remarkable, the rude figures of these early times are represented with little or no improvement of taste on the playing-cards of the present day.

As stated in the preceding sheet, immediately before, and also after the invention of printing, the practice of issuing small books composed entirely of woodcuts, representing Scripture subjects, was common in different continental countries. The people not being able to read, were in this manner impressed with glimmering ideas of sacred history. Remarkable incidents mentioned in the books of Moses, the Gospels, and the Apocalypse, were thus made known to the less-instructed classes, but generally in connection with legends of the Middle Ages. Some works of this class were called '*Biblia Pauperum*'—('Poor Men's Books'); and copies of them are now extremely rare. By such devices was the piety of our unlettered forefathers excited: the instruction being communicated to the understanding through the eye, as it is now more generally conveyed through the ear.

Wood-engraving, for the sake of illustrating printed copies of the Scriptures, was brought to extraordinary perfection by Albert Durer at the end of the fifteenth century. Instead of hard outlines, the figures were now finely shaded, and an elegant picture produced. Throughout the sixteenth century the art flourished in Holland, Germany, and Italy, and had many eminent professors. As printing advanced, it may be said to

721

have declined; the eye and the feelings were less appealed to than formerly; the intellect of the people was opening, though, it may be admitted, their taste was not correspondingly improved. Towards the conclusion of the seventeenth century, the art of wood-engraving had fallen into neglect; but in the eighteenth century it began to revive in France and England, and some good illustrations were produced. It remained, however, not in a brilliant condition, till it was taken up by Thomas Bewick of Newcastle-on-Tyne—an extraordinary self-taught enthusiast in the art. Bewick began a series of illustrations for a history of quadrupeds about 1785, and the work, when issued in 1790, attracted much attention. This work, and others on natural history, executed by Bewick, were remarkable for possessing an order of small engravings on wood called *tailpieces*, from being given at the terminations of chapters. Many of these sketches abounded in dry humour, and were highly relished by the increasing body of general readers. Here, for example, we give a copy of one of these tailpieces—a poor ewe, in the starvation of winter, or rather anticipated spring, picking at an old broom in front of a ruinous cot—a scene,

trifling as it seems, which tells a woful tale of suffering. Wood-engraving was now raised to the rank of a regular profession in England, and was greatly advanced by Nesbit, Harvey, Branston, and Thomson, both as respects elegance of design and delicacy of execution. In France and England its professors have latterly been numbered by hundreds.

Practice of Wood-Engraving.

*The Wood.*—The pieces of wood employed in wood-engraving are usually termed *blocks*. These are invariably of the box-tree—a species of wood exceedingly fine in the grain. The tree is cut across in slices with a fine saw, and the slices, after being planed smooth on the surface, are cut into square blocks of the required size. The blocks must be exactly one inch in depth—such being the height of the printing-types in which they are to stand. When a block of more than from six to eight inches square is wanted, it is necessary to join two or more pieces together, as the box-tree is too limited in diameter to furnish blocks of a large size. Blocks ready for use, of any required size, are to be had from the carpenters who supply printers with furniture for their presses, likewise from turners of fine wood, and other tradesmen. The price of a block of medium quality and size may be purchased for tenpence or a shilling per pound—a pound of wood yielding a printing-block about six inches square.

As in every other article, there are good and bad qualities of wood: that which is preferable ought to be as smooth on the surface as the finest paper, perfectly level, perfectly dry, and of a uniform yellow colour, without knots or flaws. When the tint is a darkish-red, the wood will most likely prove brittle; and when very light, it may be spongy, and will absorb ink when the cut comes to be printed. Some of the light-tinted wood has the appearance of satin-wood. Upon this no attempt should be made to engrave, it being utterly useless. Wood of various colours—as, for instance, that which is dark in the middle of the disk, and gradually getting light towards the edges—if not well-dried or seasoned, is also not good; when of this kind,

the cuts will warp, and be useless to the printer. After being used, the printer, for his own sake, should carefully wash and dry the blocks, and lay them safely aside for another occasion.

*Tools.*—The following are the articles required by the engraver on wood:—

1. A round flattish pad, made of leather, and filled with sand, on which to rest the block while engraving it. 2. Gravers.—A graver is a tool about four inches long, made of steel, with a small head or handle of wood. One side of the handle is flat, to allow the tool to rest steadily when set down. The blade, or steel part of the tool, is various in shape; some blades are thin, others are thicker. As it is the point of the blade which cuts, the sharper the blade is, so

may the edge be ground fine in proportion. Six or eight degrees of fineness are usually employed; the finest being for the more delicate lines and markings, and the broader-pointed for cutting broad and bold lines. One or more of the gravers require to be slightly bent in the blades, as shown above, to permit excavating hollowed parts. The shape of the point of this tool, as seen on its upper side, is here represented (a).

3. Tint-tools.—These are tools of various degrees of fineness, suitable to the fineness or coarseness of the tint required to be cut. While it is the object of gravers to cut lines in various directions, and of various lengths, also markings of a miscellaneous kind, tint-tools are chiefly employed to cut parallel lines close together, representing the tints of the sky. The tint-tool has a thinner blade than the graver, and, as is shown in the annexed cut (b), is much more tapering and sharp at the point.

4. A flat or gouge-tool, for cutting away blank spaces at the edges, and trimming the cut. 5. A hone or Turkey stone, on which to sharpen the various tools, and bring their edge to any required degree of slope. 6. A steel burnisher. 7. An inking slab, a dabber, and a small quantity of fine printing ink, as afterwards specified. 8. India paper, on which to take proofs. And lastly, two or three fine and hard black-lead pencils.

A sufficient stock of the above-mentioned apparatus, of fair quality, for an amateur learner, need not cost above twenty or thirty shillings.

*Drawing the Subject.*—Equipped with the proper tools and a few small blocks, the learner is ready to begin his operations. There is, however, something to be done preliminary to engraving: this is the drawing of the figures to be engraved on the wood. The ability to draw with neatness and precision, also a knowledge of effect in light and shade, are indispensable in the amateur wood-cutter, or any one who desires to rise in the profession. There are indeed wood-engravers who do not ordinarily draw, the designs being put on the blocks by artists of celebrity, but to this class we do not address ourselves. We are solicitous that no one who wishes to instruct himself in wood-engraving should think of making the attempt till he can draw on the wood the subjects which he intends to execute. This degree of skill is not alone necessary for the purpose of rendering wood-engravers independent of artists; it is also requisite to enable them to give effect to the designs which artists put on the wood. Sometimes the designs are not made by black-lead pencils, but by various shades of India ink, laid on with camel-hair pencils; and the effect of these various shadings requires to be brought out by lines and marks of different kinds—all the invention of the engraver.

Besides mere drawing, modern improvements have added another branch to this department of the art, which is called 'lowering.' The surface of the block being perfectly level, it is obvious that, while being

## ENGRAVING.

printed at a press equally true and even, every line left standing on the cut receives an equal degree of pressure. The finest lines forming a sky, for instance, receive an equal weight and impress with the deepest and broadest shadow. Now this is manifestly not as it should be; for fine lines ought to be printed lightly, and dark ones heavily. To obviate this, in printing the commoner class of cuts, the pressman lays small patches of paper below his sheet, opposite the spots to be printed more darkly than others; but this mode of patching fails to a considerable degree in making fine work, and a surer plan for bringing up the effect at press, consists in slightly lowering certain parts of the surface of the block. This may be effected as follows:

—Sketch the design on the block, and then scrape away with the scooper those parts to be printed lightly; for example, the sky, and the edges of trees, the whole in various degrees, according to the degree of required lightness. We desire to add, that beginners should not trouble themselves with this process, as it applies only to an advanced class of exercises. If lowered, the designs will require to be re-sketches on the wood; but whether lowered or not, the surface of the block must be prepared in the manner now to be described:—

The surface of the block being too smooth to receive the markings of a pencil, it is roughened, and at the same time delicately whitened all over with moistened powder of Bath brick and flake white, and the palm of the hand is afterwards passed over the block, to remove from it any gritty particles. When dry, it is ready for the drawing, which is now put upon it, care being taken that nothing is marked which is not to stand in relief. On being finished, the drawing appears to be a minute and perfect sketch on a white ground.

Besides being able to draw, the learner should be acquainted with the practice of copying and reducing from prints. For example, a wood-engraving 3 inches long by 2 inches broad is required to be made from a print 12 inches long and 8 inches broad. In this, as in all other cases, it is necessary to copy everything in exact proportion. A square frame, on which threads are stretched lengthwise and crosswise, leaving square openings, is laid on the print. Small squares to the same number are now lightly traced on the wood, and whatever parts lie within any opening in the frame are copied within the corresponding opening on the wood: thus a copy in exact proportion is obtained.

As pencil-drawing is very apt to be blurred or partly effaced by touching with the hand, it is necessary to cover the block, while working upon it, with a piece of paper. A slip of smooth, hard writing-paper is the best for this purpose: it should be neatly folded over the edges, and tied firmly round with a thread. On beginning to cut, tear off a piece of the paper from the part to which the tool is to be applied; and so remove the paper as the work proceeds.

*Engraving.*—Persons with weak sight use a strong magnifying-glass when engraving, or when closely examining the appearance of their work. We would recommend beginners to avoid using a glass, if possible, for it injures the sight with the naked eye. Persons with ordinary eyesight require no glass in wood-cutting. The work may be best executed with a strong steady northern light. In cutting by lamplight, a shade should be employed to throw the light down; and the light may be concentrated by being made to shine through a globe of water, the rays coming to a focus on the block.

The engraving is done at a table or bench of convenient height, placed below or near the light just mentioned. The engraver, seated on a chair, holds and moves about the block on the pad with the left hand, while he operates with the tool in the right, as is represented in the following cut. Great steadiness of hand is of the utmost importance, for the least cut in a wrong direction may mar, if not ruin, the effect to be produced. Until the learner becomes familiar with his tools, he should proceed gently and patiently, pushing

the graver cautiously forward at a uniform depth, and clearing out small chips or threadlike parings.

In picture-painting, innumerable tones, tints, lights, shades, nearness, and distance, are produced by apply-

ing a variety of colours, and any error can be rectified by a new touch of the brush. In wood-engraving, every kind of effect must be produced by a mere variation in the marking, first with the pencil, and afterwards with the graver; the result in printing being a variety of dark marks and lines on a white ground. The skill of the wood-engraver is therefore tested to no mean degree. On the careful and judicious disposition of his lines, and the lightness and strength of his masses of darkened parts, depend the entire effect of his labours. In executing a woodcut, the parts drawn upon remain, and the blank spaces which the pencil has not touched are cleared away.

The first lessons of a learner should consist in engraving straight parallel lines with a tinting-tool, as are here exemplified. The degree of darkness is

regulated by the thickness of the lines, and the spaces cut out between them. Take care that the lines are cut smooth and clean, free of ruggedness or breaks.

Not till pretty well grounded in the art of cutting straight parallel lines, should the learner proceed to the next steps in advance, which will consist in cutting bent and waving lines. The following cuts exhibit the nature of this progression. Having cut one or more

of these early exercises, the parts of the block not to be printed must be lowered with a flat or gouging-tool, so as to leave no parts so high as the lines. The depth to which the blank-spaces or 'whites' must be cut is regulated chiefly by their extent—the larger the space, the deeper the gouging.

Perfectured in the art of cutting lines straight, bent, and waved, the learner may proceed to cross-hatching, which consists in cutting lines at different angles, and of different lengths, across other lines, with the view of expressing graduated depths of shade. The varieties of hatching are endless, from light tones up to the darkest shadows. The annexed figure of a hand represents a familiar variety of cross-hatching.

These specimens are given more for the purpose of showing what cross-hatching is, than of inducing learners to prosecute this kind of engraving. Cross-hatching should always be sparingly employed, and in no case when an effect can be attained by simple lines; for it introduces complexity, and often too much minuteness

of detail. 'A good engraving,' as Jackson observes, 'viewed as a work of art, is not good in proportion, as many of its parts have the appearance of fine lace.' With this caution, it should be mentioned that if cross-hatching is found indispensable, the learner will require to execute it with particular care; for there is a difficulty in cutting out the whites, so as to leave continuous lines sweeping across, as in the above figure. If possible, rest the tool on the whites afterwards to be cut away; and when nothing remains as a fulcrum, a small piece of card may be laid on the block as a protective. Take care, also, not to undermine any already cut lines; for if undercut, they may break off in printing; and what is equally objectionable, will not admit of sound stereotype casts.

Apparent faults in wood-engravings can with great difficulty be remedied; and it is better for them to remain, or to execute another engraving, than to attempt improvement. Experienced engravers are sometimes able to correct errors in their cuts by what is technically called 'plugging.' A small piece of wood is dexterously drilled out of the block, and a new piece is inserted in its stead, and glued, to prevent shifting. On this new piece the correction is executed.

**Taking Proofs.**—When an engraving is finished, the workman will be gratified by seeing how it looks on paper; and this gratification he can afford himself without the aid of the printing press. The materials necessary for this operation are, as already stated, a small quantity of the finest printing ink; a smooth stone or slab to distribute it on (the back of a large strong earthenware saucer will, however, answer the purpose); a dabber, composed of wool, tightly tied up in white leather or fine silk; some India or Chinese paper; a burnisher; and a piece of card. Having smeared a small quantity of ink on the dabber, beat it for some time on the stone, that it may be distributed equally over the surface. Holding the cut steadily on the sand-bag, strike it gently with the dabber, taking care not to use any pressure whatever; the ink will thus be imparted evenly upon the surface of the lines without descending to their sides. Having cut a piece of India paper to the required size, breathe upon its smoothest side, lay it on the block, place the card on the back of the paper, and commence rubbing the back of the card with the burnisher. A very steady hand is requisite to do this effectually; for if the India paper be allowed to move, the lines will be blurred or doubled. When every part of the object on the block has been sufficiently rubbed, the operation is finished, and the proof may be removed.

A precaution may be necessary in taking proofs by the above plan—which is, to leave a border of the whites standing round the edge of the block, as something for the hand and the burnisher to bear upon. To prevent the black mass (which will of course be inked with the rest) from appearing on the finished proof, a rough one must be taken first, and the subject of the engraving cut out of it with scissors. After inking the block for the clean proof, the black border must be covered with what is left of the first impression, which protects the former from the ink during the burnishing process. Of course the border on the block must be cut away in finishing the woodcut for press.

After using, the slab should be cleaned with lye of potashes, or turpentine, and the dabber must be kept clean and soft. If these precautions are not attended to, the proofs will soon become coarse in appearance, and the cuts will be clogged. The most perfect dabber is the ball of the hand; but few will choose to soil their hands with printers' ink. Cuts are cleaned most effectually with turpentine, and they should be carefully dried before being put aside.

**Outline Figures.**—In commencing to cut figures and scenes, it is advisable to copy from wood-engravings of a simple and expressive kind. Almost all beginners commit a serious mistake in attempting to imitate the finer class of wood-engravings, which abound in minute marking. They should learn to bring out an effect in

light and shade with as few lines and hatchings as possible, never making two or more small marks where one of a bolder stretch would answer. The earliest exercises attempted should only be in outline, as is exemplified in the annexed engraving of the leaves of a plant. In this instance it will be observed what effect

is produced by a few thin and thick lines, with a very slight degree of shading.

Outline figures, or such as have but a few touches of shading, as in the annexed, may also at this stage

of advancement be engraved. In this example the lines are few, firm, and distinct, and the effect vastly superior to what could be produced by elaborate, but indifferently-executed shading. In proceeding to execute figures with shading, it is advisable to begin with those possessing few details, and as little complicated in subject as possible. Perhaps something like the following might be copied with advantage:—

Another class of exercises consists in cutting sketches of round and oval objects, in which there are strong

and sudden depths of shadow and strong and sudden lights, as in the preceding figure of the acorn.

## ENGRAVING.

It will be observed in these examples, as well as in other cuts of a simple class, that three gradations of shade require to be studied. After the pure white comes the lightest shading, consisting of only a few scratches: next we have the gray or middle tone: lastly, we have this mid tone shading down to the pure black. Pure blacks are portions of wood scarcely, if at all, touched by the graver.

About this stage of advancement the learner may exercise himself in drawing and cutting foliage of different kinds. As is well known to the draughtsman, foliage is represented differently, according to the nature of the tree. In the accompanying sketch, the

willow is represented by perpendicular markings, terminating in a point, to give the idea of its pendent foliage. A broad mass of light is usually preserved, and an increase of markings is given to one side of each subdivision of foliage, with considerable power of characteristic markings on the shade-side of the tree, besides an occasional repetition of touch for effect.

*Advanced Exercises.*—After outlined and shaded figures, the learner may proceed to figures with shadings and backgrounds, requiring a variety of light and dark lines. In beginning figures or objects with backgrounds, it is necessary to cut an outline round it, as a boundary to other lines coming against it; but this outline should not be seen in the impression of the engraving. This outlining prevents the figure from appearing to adhere to the background, and is indispensable.

In this department of study the learner may engrave human figures, animals of different kinds, and rural and street scenes with skies; beginning, for example, with such as have few objects, and little complexity of light and shade, as in the following sketch:—

After some practice with sketches of this nature, he may proceed to others of a more complicated kind, and in which the contrasts of light and shade are bolder, and require more delicate handling. In this, however, as in many other things, much must be left to the taste, the patience, and the skill of the engraver. Beyond this it is unnecessary to offer any hints in this brief and rudimentary description. Those who wish to pursue the profession of wood-engraving, will find it advantageous to consult the elegant and elaborate treatise of Mr Jackson. (C. Knight, London, 1839.)

### Wood-Engraving as a Profession.

Wood-engraving is carried on as a profession chiefly in London, where there are some extensive establishments devoted to this line of business. In these, as in all other large concerns, it is not unusual to have a division of labour: a cut being made to go through several hands, from the drawing to the finishing. By such means cuts can be produced with surprising rapidity; but it may be doubted if this wholesale system of production is advantageous to art. The too-common failing of woodcuts is their want of character and truth. They may be neat, elegant, and highly-finished, but not striking for their fidelity, and too ambitiously imitative of steel or copper-plate engravings. Woodcuts should possess a character of their own, which cannot be mistaken; and to attain this character for his productions ought to be the aim of every artist.

Another, and perhaps more serious fault of many woodcuts, is their not being adapted to the kind of printing for which they are intended. There are now two kinds of letterpress printing, very different from each other—printing by flat pressure with the hand-press, and printing with cylinder machines, moved by steam power. At the hand-press, cuts can be worked off with the greatest possible deliberation and care; and if inked by means of soft balls, any degree of colour can be imparted to them. At the printing-machine, no such pains can be taken: a common or easily-working ink must be employed; the rollers run over the *forms* with uncompromising speed; and the cylinders, turning out ten or twelve sheets per minute, give a depth of impression which is fatal to delicacy of lines. Now the misfortune is, that wood-engravers do not sufficiently study these distinctions. In sending home their cuts to their employers, they give along with them proofs on India paper, which look exceedingly beautiful; and if the cuts were to be printed on India paper with fine ink, the work would be quite answerable. Such, however, is not the case. Perhaps as many as nine-tenths of all the cuts executed are for machine-printing, with which it is impossible to do them on all occasions justice. Hence the many blurred and ineffective cuts which are seen in books, all the tones being confounded, and often only a gray haze pervading the work. Not that these cuts are badly executed, but that they are suited to an entirely different process of working.

We mention these circumstances with the view of doing all in our power to inspire amateur learners with a correct idea of the deficiencies as well as the excellencies of wood-engraving in its present state of advancement. We wish to show them not only what they should attain, but what they ought in prudence to avoid. Already it has been stated that, without a knowledge of drawing, all attempts to prosecute wood-engraving successfully must prove fruitless. Let us repeat and impress this fact on the mind of every one who thinks of taking a graver in hand. Let all who are deficient in this qualification procure instruction; and we know of no better seminaries than the Schools of Design now generally established throughout the country. Learn, we say, to sketch with fidelity from nature, to copy from prints and paintings, to acquire taste in grouping, and disposition of light and shade, and to design subjects in illustration of passages in stories, &c. Having acquired a certain proficiency in these departments, which involve much miscellaneous knowledge, the amateur may proceed to wood-cutting, *but not till then.*

The surmounting of so many preliminary impediments will no doubt require time and trouble; but no attainment of any value can be acquired without industry and patience. The attainment in the present instance is worthy of more than the usual degree of labour. It is the acquiring of an art which may be turned to most important uses. To those in easy circumstances, it may be a delightful and elegant exercise. To others less fortunate in worldly condition, it

may become a ready means of subsistence. There are few things on which human labour raises the value so highly as wood-engravings. A small piece of wood, worth no more than two or three shillings, may, by a few days of skilful industry, become worth as many pounds. Surely, to be able to impart this high value to an object next to worthless in its raw state, must be deemed no mean talent.

The ease with which wood-engraving can be executed within the domestic circle, peculiarly adapts it as an occupation for ladies. On this point we cannot do better than offer the following passages from an article on wood-engraving in the 'London and Westminster Review' for 1838:—"To that large portion of educated gentlewomen of the middle-classes who now earn a subsistence chiefly as governesses, we wish to point out this art as an honourable, elegant, and lucrative employment, easily acquired, and everywhere becoming their sex and habits. We have already done honour to the exquisite delicacy and elegance of the engravings of Mary Ann Williams; we venture to say that few women of taste, whatever their rank in life, can look on "Le Jardin du Paria au lever de l'Aurore" without envying the artist her power of producing a scene so beautiful, and of exciting in thousands the pleasing emotions inseparable from it. Apart from all pecuniary considerations, to be able to do it is an elegant accomplishment; and the study of the principles and details of taste which it implies, is a cultivating and refining process to every mind. All that can be taught of the art may be learned in a few lessons, and thus an acquirement made which will afford no slight protection against misfortunes to which, in this commercial country, even the richest are exposed—and a means of livelihood obtained which, without severing from home, without breaking up family assemblies, is at once more happy, healthy, tasteful, and profitable, than almost any other of the pursuits at present practised by women. The lady we have named is not alone in the practice of this art: we might name also Eliza Thomson, and Mary and Elizabeth Clint, who have furnished excellent engravings for the "Paule et Virginie;" and we have heard of several daughters of professional and mercantile men, not likely to be dependent on their own exertions for support, who have wisely, by learning this art, acquired both an accomplishment and a profession. The occupations, we may also add, are few, indeed, to which gentlewomen of this class can more worthily devote themselves, than to an art which is peculiarly fitted to enhance the enjoyments and refinements of the people, by scattering through all the homes of the land the most beautiful delineations of scenery, of historic incidents, and of distinguished persons."

#### ENGRAVING ON COPPER AND STEEL.

In the printing of letterpress or woodcuts, as has been already noticed, the impressions are effected by the raised faces of the letters, or marks, in the manner of a stamp. Printing from engraved plates is performed on a principle directly the reverse: in this case the face of the metal, cleared of the ink daubed upon it, gives no representation—the printing is effected from the sunk lines. While wood-engravings may be printed along with type-matter, engravings on plates of metal require to be printed by themselves.

The discovery of the art of engraving on metal, for the purpose of making impressions on paper, is generally ascribed to Finiguerra, a goldsmith of Florence. He excelled in an art then much practised in Florence called *niello*. It was the custom with jewellers, in those times, to engrave the outlines of Scripture subjects upon the vessels which they made for the use of the church. When this engraving was completed, they filled the lines with a black substance composed of a mixture of lead and silver, in solution with borax and sulphur; and impressions were taken from this in clay or sulphur. The black substance used was called *niello*, and hence the name of the art. The same process was

also used when pieces of armour, household plate, and other articles, were engraved for the purpose of being inlaid with metals, wood, or ivory.

German writers claim the honour of the invention for a citizen of Antwerp, Martin Schoengaur, asserting that he practised the art before Finiguerra. It seems probable that it appeared nearly simultaneously in both countries. The earliest distinguished engravers, after the discovery of the art, however, were Italians.

It does not appear that Finiguerra pursued his invention any further than to take impressions on paper instead of clay. A contemporary, of the same profession and city, Baccio Baldini, improved upon the invention by engraving on plates for the express purpose of taking impressions on paper. He was greatly assisted by a distinguished painter, Antonio Pollajuolo, who furnished him with designs for his engravings, and also by another artist, Sandro Botticelli, who made a set of drawings, from which Baldini engraved plates for an edition of Dante, published in 1488, and supposed to be the first book ever embellished with copperplate engravings; though this notion has been proved false by a German writer. The works of Baldini attracted the attention of a Roman engraver, Andrea Mantegna, who had already become distinguished as one of the most successful of the *niellatori*. This artist not only assisted Baldini with original designs, but also turned his own efforts to the promotion of the newly-discovered art, in which he soon became a proficient.

In our notice of the early days of the art, we must not omit mentioning Albert Durer, one of the earliest Dutch engravers. Some knowledge of the art seems to have been previously possessed in Holland by Martin Schoengaur, who is thought by some German writers, as we have seen, to have invented it, and who was certainly a contemporary of Finiguerra. The works of Martin, and his disciple Wolgemuth, inspired the genius of Albert Durer, who did much for the improvement of the art, excelling equally on copper and on wood. Marc-Antonio Raimondi, an Italian artist, having seen Durer's prints, improved upon them, and became at Rome a master in the art. Thus the profession was spread simultaneously over Holland and Italy. Although there have been various improvements in the art since this early period of its history, the mode of etching the plates remains substantially the same. At present there are several kinds of engraving practised, each effected in a different manner, and of these we shall now offer a short account:—

*Line-Engraving.*—This is the principal as well as the most ancient species of engraving. When not executed entirely with the graver and dry point—that is, when the lines are not cut mechanically and finished with the scraper and burnisher—it is commenced by a chemical process called *etching*. The plate is first cleaned on its polished surface, and heated sufficiently to melt a composition of asphaltum and Burgundy pitch, called *etching-ground*, which is rubbed upon it, and rendered equal all over, by dabbing with a ball of wool covered with silk. The plate is then held up for the surface to receive the smoke of a wax taper, until it is rendered black and glossy, into which state it comes on not being suffered to cool during the process. These preparations being effected, and the plate becoming cold, the *etching-ground*, which is not thicker than a coat of varnish, is found to be of a hard consistence, and ready to receive the tracing of the subject intended to be etched. The previous preparation of the subject is a very important step in the process. The subject is drawn upon transparent paper with a black-lead pencil, and being laid with the face downwards on the *etching-ground*, the lines or marks of the drawing are pressed upon it with such force, that they are left on the ground on removing the paper. This is called 'transferring;' and of course the excellence of the representation to be produced depends on the excellence of the drawing. Engravers, therefore, in copying paintings, require to possess a degree of skill in the art of delineation hardly inferior to that of the original artist.

## ENGRAVING.

The drawing being transferred in the manner described, the engraver applies his tool, or etching needle, over the lines, carefully removing the ground, at the same time pressing sufficiently hard to scratch the surface of the copper. When any error has been committed, the objectionable lines may be stopped out by working a little of the ground over them with a hair-pencil dipped in turpentine. When set, the parts so treated resist the aquafortis. A wall of wax is now placed round the margin of the plate, and into the enclosure so formed aquafortis is poured, to the depth of half an inch. This aquafortis decomposes or bites into the copper where the etching-ground has been removed. During this process, globules of air arise from the decomposition, and these are carefully removed with a feather, to allow free scope to the biting liquid. The length of time employed in biting the plate is regulated by the depth required, also by the state of the atmosphere; in ordinary cases, the operation may be performed in about an hour. When it is ascertained that the plate is properly acted upon, the aquafortis is poured off, the wall of wax removed, and the ground cleared with spirits of turpentine. The plate is now said to be etched, and when printed from in this state, exhibits the appearance of a pen-and-ink sketch. To this state of etching, but regulated by the nature of the subject, professional engravers bring the plates to be finished in the *line* manner. Different gradations of power are given by the aquafortis, and parts are rebitten to the depth required; after which, the light parts are put in with a sharp needle. Other parts are then cut with gravers of various sizes and forms, suited to the lines which will best express the respective objects. The engraver, in thus finishing his work, rests the plate on a small cushion, so that it may be conveniently turned with the left hand, while the incisions are cut with the graving tool by the right. These lines are re-entered, crossed in various directions, or cut in the spaces between the diagonal crossings, until the desired effect is produced. Landscapes and architecture are generally executed with the needle and aquafortis: portraits and historical subjects are chiefly cut with the graver or burin, without the use of aquafortis. Where a series of parallel lines are wanted, as in backgrounds, &c. an ingenious machine, called a *ruler*, is employed, the accuracy of whose operation is exceedingly perfect. This is made to act on etching-ground by a point or knife connected with the apparatus, and bit in with aquafortis in the ordinary way.

As etching has become somewhat fashionable, and is now pretty freely cultivated by amateurs, either as an amusement, or with a view to illustrate discoveries in natural science, it may be well to mention that the art can be learned in a few lessons. Those who reside in large towns, will most readily acquire it under the direction of some copperplate-engraver; those who have no such opportunity, may teach themselves by attending to the directions given in Mr Alken's 'Art and Practice of Etching,' published by the Messrs Fuller, Rathbone Place, London, who also supply the entire apparatus. The apparatus is by no means costly, and consists of a few copper-plates, etching-needles, a hand-rest, a ball of etching-ground, a dabber, oil-rubber, a little rottenstone, a smoking-taper, bordering-wax, some varnish for stopping out false lines, tracing-paper, and a phial of aquafortis. The great advantage of etching to the amateur consists in the opportunity it affords him of multiplying impressions of his work. A sketch in oil or in water-colours remains single, and a copy can only be obtained by repeating the process; whereas a sketch once etched can yield hundreds of impressions, all precisely the same in every line and feature. Those who can draw in reverse proceed at once to delineate on the etching-ground; but in general it is safer to draw on paper, and transfer. Etching with a *dry point*, as it is called, is performed entirely with the point without any ground, the burr raised by the graver being taken off by the scraper—a steel instrument with three sharp edges. Engraving or etching in

*soft ground* is used to imitate chalk or pencil-drawings. For this purpose the ground is mixed with a portion of tallow or lard, according to the temperature of the air. A piece of tissue-paper being attached to the plate at the four corners by some turners' pitch, and lying over the ground, the drawing is made on the paper, and shadowed with the blacklead pencil. The action of the pencil thus detaches the ground which adheres to the paper, according to the degree to which the finishing is carried; the paper being then removed, the work is bit, as in etching with the hard ground.

*Stippling* is a style of engraving in which dots of various sizes and depths in the copper, instead of lines, express the forms and shades of the subject. They are first made in the etching-ground with the needle, or with a toothed-wheel called a *roulette*, then bitten, and some parts stopped out, to prevent the further action of the aquafortis on them; while other parts receive additional bitings, till the subject has the power required. After this the plate is cleaned, dotted up with the needle, stippled with the graver, or rebitten, until all the gradations of force are communicated.

*Mezzotinto* is in a great measure a reversal of those styles already described, being the reducing of a darkened surface of copper to one that is light. The operation is generally commenced by grounding or puncturing the plate with a circular-faced tool, called a *cradle*, on the edge of which are a number of points; this instrument, by being rocked regularly over the surface of the copper in every direction, covers it so completely with marks, that, if it were printed from, the impression would be perfectly black. On this dark ground the subject is traced, directing where the various gradations of light and half-tint are to be scraped and burnished out, until the proper effect is produced. This style of engraving is used chiefly for portraits and historical subjects. It has a pleasing soft appearance, but it is understood that the copper soon fails in producing strong impressions, and it is therefore not well adapted for subjects of which great numbers are required.

*Aquatinto* engraving is an exceedingly complicated style of producing pictorial effect; but being executed at a lower price than that of the kinds previously mentioned, it is commonly resorted to for embellishing books of travels, or other works requiring illustrations of a simple nature. In appearance it resembles tinting with Indian ink, and the prints are susceptible of being finished with water-colours. In commencing the process of aquatinto engraving, the plate must be cleaned with an oil-rubber, which is a strip of woollen cloth rolled up hard, to about two inches in diameter; this, with a little impalpable crocus and sweet-oil, will give to the copperplate, when perfectly cleaned from the oil, a proper surface to receive the ground, which is made with pulverised sifted rosin and spirits of wine, incorporated by gentle heat, till it appears like a varnish. This composition is poured over the plate while placed in a slanting position, so as to permit the superfluous liquid to run off. The operation must be so managed as to preserve an equal surface. As soon as the granulation, or drying of the grain, appears, the plate must be placed horizontally, when the spirit will evaporate, and the particles of rosin will adhere to the copper. When dry, the surface appears evenly covered, as with a diminutive honeycomb, and perfectly smooth. On this the subject is traced, and the highest lights painted out with a sable pencil in a mixture of turpentine-varnish and lampblack, so as to prevent the aquafortis acting on those parts. The margin is also covered, and on it a wall of wax is fixed, with a spout at one corner. The aquafortis is regulated in its strength by the temperature of the weather and the hardness of the copper. Being poured on the plate, it remains until the first gradation of tint is bitten—the aquafortis having acted on the copper between the particles of rosin which adhered to the plate. The aquafortis is then taken off, the plate dried, and this first degree of tint stopped out or covered over with the blackened varnish. When hard, the aqua-

fortis is again poured on, to bite the second degree of tint; and so on until all the tints have in succession been bitten in. The copper must then be cleaned, and a proof taken and compared with the original. A similar or rebiting grain must then be laid on the plate as before; when cold, a composition of treacle and lamp-black, well mixed, must be used to paint the projections of foliage on lights, or other touches which the masses of tint may require. When these are dry, the whole of the plate must be washed over with a thin coat of varnish reduced with turpentine, which will adhere to the untouched parts of the work. The wall of wax must then be replaced, and clean water poured on; in a short time the water will mix with the treacle touches, and loosen them. When all appear to be removed, the water is taken off, and aquafortis poured on, and allowed to remain until a sufficient degree of power is given to the touches, and the subject completed. This mode of engraving was invented by a Frenchman of the name of St Non, about the year 1662. He communicated the process to Jean Baptiste le Prince, who died in 1781, from whom it was acquired by Paul Sandby, who introduced it, through the medium of Mr Jukes, into this country. It has been practised in England with much greater success than anywhere else, but latterly has been superseded in many instances by lithography.

*Plate-Printing.*—Copperplates, engraved in any of the above styles, are ready for press as soon as they are finished by the engraver. The method of printing from them is very simple. Their engraved surface is daubed over with a thick oleaginous ink, so that the lines are effectually filled. As this dirties the whole face of the plate, it is necessary to clean it, which is done by the workman wiping it first with a piece of canvas, and then with the palms of his hands, rubbed on fine whiting. It may be calculated that a hundred times more ink is thus removed than actually remains in the indentations; however, such is necessary. The plate being thoroughly cleaned, it is laid on a press (see fig.), with a piece of damped paper over it, and

being wound beneath a roller covered with blanket stuff, it is forced to yield an impression on the paper. The plate requires to be kept at a moderate warmth during the operation. The frequent rubbing of the plate with the hand to clean it, as may be supposed, tends greatly to wear it down; and such is the wear chiefly from this cause, that few copperplates will yield more than a few thousands of impressions in good order. The earliest, called *proofs*, are always the best, and most highly prized.

In consequence of this defect in copper, the practice of engraving steel plates, for all subjects requiring long numbers, has now become very common. This process was introduced by the late Mr Perkins of London, who originally softened the plates, engraved them, and then rehardened them—a practice now abandoned, as ordinary steel plates can be worked upon by the burin, dry-point, scraper, and burnisher with perfect facility. Etching on steel plates is executed much in the same way as in the process on copper. The plate is bedded on common glaziers' putty, and a ground of Brunswick

black is laid on in the usual way, through which the needle scratches. The biting menstruum is then poured on, and managed in the manner already detailed. An engraving on a steel plate may be transferred in relief to a softened steel cylinder by pressure; and this cylinder, after being hardened, may again transfer the design by rolling it upon a fresh steel plate; and thus the design may be multiplied at pleasure.

SEAL AND GEM ENGRAVING.

This is a branch of the profession altogether distinct from that of engraving on metallic plates. While the hardest metals are susceptible of being cut by a tool wielded by the hand of the artist, the different kinds of stone required to be operated upon by the seal-engraver are so extremely hard, that a much more powerful instrument than the hand has to be resorted to. The cutting-tool is fixed into a turning-machine or lathe, and is made to operate while in a rapid rotatory motion. The lathe is of a light and miniature construction, erected on an elevated bench or table in front of the artist, and is moved by a foot-board beneath. The engraver of metal-plates sits while at his work, but the seal-engraver in general stands, in order to have greater command over his operations. He likewise requires to be exceedingly steady in the hand, for the slightest error would perhaps be irremediable; therefore, with both his elbows resting on cushions on the bench, and the palm of his left hand leaning on the top of an erect roundish-shaped bolt or pillar, his fingers of both hands are busy in pressing the stone to the edge of the whirling-tool, or guiding it so that it may receive the appropriate indentations. One tool, however, cannot execute all parts of the device. The cutter possesses from one to two hundred tools, usually of soft iron or copper, varying from a large to a small size. It is also necessary to explain that the cutting part of each tool is shaped so as to present to the stone a sharp thin edge like the rim of a wheel. (By sticking a small wafer on the point of a pin, and conceiving the edge of the wafer, when turning round, to be the cutting part, a good idea may be obtained of this curious instrument.) As the tool projects horizontally, the artist, by holding the stone beneath it, with its surface to be cut uppermost, is thus enabled to watch the progress of his operation from beginning to end.

Sharp as the cutting tools of the seal-engraver are, they would entirely fail in perforating the gems to which they are applied by the lathe, unless they were given an additional sharpness by means of a foreign material occasionally applied to them while in rapid motion. This material is usually diamond dust, or the powder of the ruby and other hard stones. The diamond is so expensive an article, that the particles used by the seal-engraver are those which have been rejected as waste by the lapidary. These being placed in a hollow steel tube, having a tight-fitting rammer of the same material, a few smart blows on the upper extremity of the rammer reduce the particles to powder. A small portion of this dust is then mixed with a little olive oil, and being held to the tool in a state of motion, it is attached to or forced into the metal. If a powerful magnifying-glass were taken to examine the tool after its absorption of the diamond dust, its edge would be observed to resemble a rasp or saw, the particles being partly imbedded and fixed in the steel; hence, properly speaking, it is not the tool, but the diamond dust upon it, which cuts the surface of the stone.

To cut an elaborate device, such as a bust or a coat of arms, upon the surface of a cornelian or other gem, a vast deal of care is necessary on the part of the artist. The precise depth of every turn and indentation is matter of serious study, and a momentary heedlessness might have the effect of ruining the work of several days. The operator, however, exercises caution in his ingenious labour. The stone being dimmed by friction, is drawn upon with a brass point, to show the subject, which is of course reversed: the artist first traces the outlines of his figures, next opens them with

## ENGRAVING.

the bolder tools, and gradually proceeds to the details with finer and finer instruments, frequently stopping to take impressions on wax, to see the effect which has been produced, before he gives the finishing stroke to his workmanship; lastly, the surface is repolished, and the seal completed.

It will thus be seen that gem-engraving requires not only great ability and skill, but a degree of patience and perseverance beyond what is required in most other professions. To cut a metallic seal or die is comparatively an easy task—the instruments as well as material being thoroughly under the control of the artist; but to engrave on the hardest gems, whose nature cannot be altered, and which, if destroyed, cannot be replaced—to carve the most minute and delicate figures, and to produce them in such a manner as to yield a distinct and smooth impression—is altogether an art of the highest order.

### ENGRAVING AND ETCHING ON GLASS.

The name of *cut glass* is given in commerce to glass which is ground and polished in figures with smooth surfaces, appearing as if cut by incisions of a sharp instrument. This operation is chiefly confined to flint-glass (see No. 21), which, being more tough, soft, and brilliant than the other kinds, is more easily worked, and produces specimens of greater lustre. An establishment for cutting glass contains a great number of wheels or disks, seldom exceeding a foot in diameter, which are made to revolve with great rapidity by steam or other moving power. Against the circumferences or edges of these revolving wheels the glass to be ground or figured is held by the hand of the workman. The thickness of the cutting disks, and the forms of their edge, are varied considerably; some being broad, others narrow; some convex, others concave; some flat-edged, others wedge-shaped; and so on, according to the shape of the vessel and the figures to be produced. Even forty or fifty disks with different-shaped edges may be found in the same workshop. Materials of very different degrees of hardness, from cork to wrought-iron, are employed in the formation of these disks. Those made of wrought-iron, which are very thin, are used to cut grooves in glass, by the aid of sand and water, which are caused to drop on the circumference of the disk from hoppers placed above. Cast-iron disks are also sometimes used in the roughest part of the operation; but the coarse work is usually done by a disk of fine sandstone wetted with water. When ground down to the proper shape, the glass is polished by exposure to softer disks, the action of which is generally assisted by various powders applied in a moist state to the circumference. Thus a copper disk is used with emery and oil; a disk of block-tin with peroxide of tin or tatty; a disk of willow-wood with fine pumicestone, colcothar, or putty; and a cork disk having an edge of hat-felt with putty or colcothar. By such simple instruments is all that variety of design—flower, fruit, foliage, arabesque tracery, initials, armorial bearings, &c.—produced which now adorns so abundantly the most familiar articles of domestic utility.

The art of *etching on glass* is altogether different, being akin to etching on plates of copper and steel. 'The art,' says Parnell in his 'Applied Chemistry,' 'may be practised on all kinds of glass; but the most proper description is good crown-glass. The facts on which this art is founded are, that the vapour of hydrofluoric acid (see No. 19) acts energetically on glass, corroding it as aquafortis does a sheet of copper, and that certain parts of the glass may be easily protected by a resinous varnish, on which the acid exerts no action except at a high temperature. The varnish usually employed by artists for this purpose is either common turpentine varnish mixed with a little white-lead, or a strong aqueous solution of isinglass. In performing the process on a small scale, purified bees'-wax will be found to form a convenient varnish.

The piece of glass to be etched is first of all warmed in a convenient manner, and one of its surfaces is then

rubbed over with wax, the temperature of the glass being high enough to cause the wax to melt, and be distributed uniformly over the entire surface. The glass is then set aside to cool; and when the wax has become quite solid, the design may be traced with a pointed, but not very fine instrument, such as a bodkin. A carpenter's bradawl is a convenient tool for this operation, since, from being flattened at the end in one direction, it may be made to trace lines of different degrees of fineness, according to the position in which it is held. Care must be taken to cut through the entire thickness of the wax, so as to lay the glass quite bare through the whole length of the line.

The next part of the process consists in the application of the hydrofluoric acid. The vessel employed for this purpose is a shallow basin, either of lead or of Wedgwood's ware (no glazed vessel should be employed), large enough to include within its area every part of the design, when the prepared glass is placed upon its edge. The materials for generating hydrofluoric acid—consisting of one part of powdered fluor spar, and about two parts of highly concentrated oil of vitriol—are introduced into the basin, and well mixed; the glass plate is then laid on the edge of the basin, with the waxed side undermost, and a moderate heat is applied, to disengage the vapour of hydrofluoric acid. A spirit-lamp will be found a convenient source of heat, from the facility it affords of increasing or decreasing the temperature at pleasure. Care must be taken to prevent the heat becoming so powerful as to melt the wax-ground.

After being exposed to the acid fumes for a few minutes, the glass plate may be removed and cleaned. The lines where the wax had been removed are found to be covered with a white powder, which consists of silico-fluorides of the metallic bases of the glass. The greater part of the wax may be removed by scraping with a common table-knife, and the remainder by warming the glass before the fire, and wiping it with tow and a little oil of turpentine. The design will then be found to be perfectly etched upon the surface of the glass, the depth of the lines being proportional to the time the glass was exposed to the acid vapour. In conducting the operation, care should be taken not to allow the hands to become exposed to the acid fumes, as the vitality of the parts would be instantly destroyed by the action of the acid. According to the authority now quoted, a dilute aqueous solution of hydrofluoric acid may be substituted for the vapour in the above process with a similar result.

Glass plates engraved upon in this manner are not adapted for printing, or yielding impressions upon paper, on account of their brittleness; but even this has been partially obviated by a German invention, wherein the glass, of considerable thickness, is cemented to blocks of wood—the plates so mounted enduring sufficient pressure to produce a fair impression without fracture.

### GLYPHOGRAPHY.

An important addition to our means of producing pictures or impressions consists in the glyphographic process of Mr Palmer. The peculiar advantages of this invention—so named from its combining two distinct operations of drawing and engraving—are thus detailed by the patentee:—'The term glyphography is derived from two Greek words (*glypho*, I engrave, and *graphein*, to draw), and signifies that art by which an engraving is produced by the simple mode of drawing; or, in other words, drawing and engraving, which have hitherto been two distinct operations, are here combined in one. Hence its merits, and importance to every artist, seeing that by its aid he becomes the engraver of his own work, as much as he would by the practice of etching; but with this vast difference, that here his effect is as immediately conspicuous as though he were using a black-lead pencil on paper; whilst, on the contrary, effect is obtained in etching in the same manner as in line-engraving—namely, by depth; and that depth the etcher produces by the action of acid on

the copper, called *biting*; nor has he any means of ascertaining the real effect thus produced but by taking a proof on paper, and of course he must repeat this as often as he makes any alteration in his plate. Another material advantage which glyptography possesses over etching and wood-engraving is, that in the former the artist draws his subject as he intends it to appear, without reversing it, as is requisite in both the latter, and which is extremely difficult and perplexing, at least to beginners. And last, though by no means least of its peculiar merits, and that which makes it of the highest importance to every true lover of the fine arts, is the freedom afforded to the artist, and consequent scope for the exercise of his talent, and multiplication of fac-similes of his own work. Every connoisseur in the arts knows what sort of comparison to make between etchings and any other kind of prints, although they may be the productions of the same hand; and why? Simply on account of the stiff formality and studied regularity of the latter, which, though perhaps pleasing to the eye, are by no means natural; consequently the same facilities are here afforded as in etching, without that tediousness associated therewith, and the other disadvantages already enumerated. So tied and fettered is the wood-draughtsman, that he is obliged to leave the tints entirely to the engraver's taste and skill, contenting himself with staining with India ink, &c. that part of the block to the desired colour or tone; nor is his outline secure, unless in the hands of a clever cutter, and even then its freedom and beauty are sometimes entirely spoiled from a variety of causes; but in glyptography, on the contrary, any sort of work, whether sketchy or finished, free or formal, is introduced with equal ease (according to the skill and experience of the artist); and, moreover, what may seem strange to those unacquainted with the nature of the after-process, the more elaborate and complicated the drawing, the less time and trouble is required in its conversion into a surface-printing block, as hereafter described.

If anything further needs observation here, regarding the many advantages that this new art possesses, it is, first, the durability of the blocks, seeing that, with care, the number of proofs taken therefrom may be multiplied almost *ad infinitum*, upwards of 70,000 having been taken from one without altering in the least degree its sharpness; and next, in a commercial point of view, is its extreme cheapness, which of course is worthy of consideration.

Such are the proffered advantages of the invention; let us now glance at the process so far as divulged by Mr Palmer:—'A piece of ordinary copper-plate, such as is used for engraving, is stained *black* on one side, over which is spread a very thin layer of a *whites* opaque composition, resembling white wax both in its nature and appearance: this done, the plate is ready for use.

In order to draw properly on these plates, various sorts of points are used, which remove, wherever they are passed, a portion of the white composition, whereby the blackened surface of the plate is exposed, forming a striking contrast with the surrounding white ground, so that the artist sees his effect at once. The drawing being thus completed, is put into the hands of one who inspects it very carefully and minutely, to see that no part of the work has been damaged, or filled in with dirt or dust; from thence it passes into a third person's hands, by whom it is brought in contact with a substance having a chemical attraction or affinity for the remaining portions of the composition thereon, whereby they are heightened *ad libitum*. Thus by a careful manipulation the *lights* of the drawing become thickened all over the plate equally, and the main difficulty is at once overcome; a little more, however, remains to be done. The depth of these non-printing parts of the block must be in some degree proportionate to their width; consequently the larger breadths of *lights* require to be thickened on the plate to a much greater extent, in order to produce this depth. This part of the process, however, is purely mechanical, and easily accomplished.

It is indispensably necessary that the printing surfaces of a block prepared for the press should project in such relief from the block itself as shall prevent the probability of the inking-roller touching the interstices of the same whilst passing over them; this is accomplished in wood-engraving by cutting out these intervening parts, which form the lights of the print, to a sufficient depth; but in glyptography the depth of these parts is formed by the remaining portions of the white composition on the plate, analogous to the thickness or height of which must be the depth on the block, seeing that the latter is in fact (to simplify the matter) a cast or reverse of the former. But if this composition was spread on the plate as thickly as required for this purpose, it would be impossible for the artist to put either close, fine, or free work thereon; consequently the thinnest possible coating is put on the plate previously to the drawing being made, and the required thickness obtained ultimately as described.

The plate thus prepared is again carefully inspected through a powerful lens, and closely scrutinised, to see that it is ready for the next stage of the process, which is, to place it in a trough, and submit it to the action of a galvanic battery, by means of which copper is deposited into the indentations thereof, and continuing to fill them up, it gradually spreads itself all over the surface of the composition, until a sufficiently thick plate of copper is obtained, which, on being separated, will be found to be a perfect cast of the drawing which formed the *dichée*.

Lastly, the metallic plate thus produced is soldered to another piece of metal to strengthen it, and then mounted on a piece of wood, to bring it to the height of the printer's type. This completes the process, and the glyptographic block is now ready for the press. It should, however, have been stated previously, that if any parts of the block require to be lowered, it is done with the greatest facility in the process of mounting.

What progress Mr Palmer's process may be making as a substitute for wood-engraving we have no means of knowing. Very delicate and beautiful specimens of glyptography have appeared in the Art Journals; but in volumes which have been illustrated throughout by the process, and printed in the usual manner—such as Dr Lindley's botanical works—while the drawings have undoubtedly considerable breadth and freedom, the impressions are vastly inferior in delicacy and clearness to those from ordinary woodcuts.

#### LITHOGRAPHY.

Lithography (Gr. *lithos*, a stone, and *graphein*, to draw) is the art of printing from a peculiar kind of stone, and generally in a style which resembles the more ordinary kinds of engravings. It was invented at Munich in Bavaria, between the years 1795 and 1798, by Aloys Sennefelder, a person of literary ability, who, being too poor to pay for the printing of books in the usual manner, endeavoured to fall on a method of executing his productions from the surface of various metals. 'He found'—we quote the 'Encyclopædia Americana'—'in the course of his experiments that a composition of soap, wax, and lampblack formed a good material for writing on his plates; that, when dry, it became firm and solid, and that it resisted aquafortis. Wanting facility in writing backwards on the plates, he got some pieces of Kilheim-stone, as cheap materials on which he could practise after polishing their surfaces. One day, being desired by his mother to take an account of some linen about to be sent to be washed, and having no paper at hand, he wrote the account on a polished stone with his composition ink, intending to copy it at his leisure. When he was afterwards about to efface this writing, it occurred to him that he might obtain impressions from it; and having eaten away the stone with acid for about the hundredth part of an inch, he found that he could charge the lines with printing-ink, and take successive

## LITHOGRAPHY.

impressions. This new mode of printing appeared to him very important, and he persevered through all difficulties in applying his discovery to practical purposes, and in improving it. In the course of many experiments, he found that it was not necessary to have the letters raised above the surface of the stone, but that the chemical principles by which grease and water are kept from uniting, were alone sufficient for his purpose. This point obtained, lithography may be said to have been fully discovered. The first essays to print for publication were some pieces of music, executed in 1796: afterwards he attempted drawings and writings. The difficulty he had in writing backwards led him to the process of *transfer*; and the use of dry soap, which was found to leave permanent traces, which would give impressions, naturally led to the mode of chalk-drawings.

Having made considerable improvements, Mr Sennefelder obtained, in 1799, a patent privilege for Bavaria, when he made known his process, and afterwards entered into partnership with Mr André of Offenbach, who proposed to establish presses, and take out patents in London, Paris, and Vienna. For this purpose Sennefelder went to London with a brother of André's; and the invention having been much spoken of, under the name of *polyautography*, most of the principal English artists made trials of it. Unfortunately, however, the art of printing from the stones was not then fully understood, and the difference between the materials of Germany and those of England, used both for the purposes of drawing and printing, caused constant failures; and the artists, in succession, abandoned the practice of it. In August 1800, Sennefelder, who had separated from André, went to Vienna, where, after much difficulty, a patent was obtained, and extensive preparations were made for applying his process to print cottons; but bad management, and some unfortunate circumstances, prevented his success, and he returned to Munich in 1806, leaving the establishment in other hands. Mr Mitterer, professor of drawing at the public school of Munich in 1806, practised lithography to multiply copies for the pupils, and is said to have invented the chalk composition in its present form, or at least to have improved it greatly. From this period the practice of the art was improved and extended; from Munich it shortly spread over Germany; and from thence to France and England.

The stone employed for lithography is a species of limestone, resembling in appearance a smooth yellow hone, and is found in quarries in Bavaria; it is likewise found in France and England; but no stones have as yet been found to surpass those of Solenhofen in Bavaria. Any stone which effervesces with an acid, which imbibes water with facility, and is easily penetrated by greasy substances, is fit for lithographic purposes; the nature and quality of the work requiring a stone of corresponding quality and fitness. The best for general purposes is that which breaks with a conchoidal fracture; is of a homogeneous texture, and of a uniform yellowish white; and emits, when breathed upon, an aluminous or clayey odour. The stone, when prepared, usually varies in thickness from an inch to four or five inches; those which are large requiring the greatest thickness, in order to endure the severe pressure to which they are subjected. Of whatever dimensions, the stones require to be perfectly flat, and of uniform polish on the printing surface. For this purpose, they are sawn into blocks, polished with sifted sand and water, till they acquire the necessary *grain* or surface, if for chalk-drawings; and if for ink-drawings, they must be polished with pumicestone till they are perfectly free from grain or scratches. Stones which have been printed from must be polished afresh, to remove the old drawing; and in addition to the usual rubbing with sand and pumice, must be washed with a mixture of aquafortis and water.

The ink to be employed in making the drawings for the stone varies in composition according to the precise nature of the work, and whether the drawing is made

direct on the stone, or transferred to it from paper. One kind, of a good quality, consists of dried tallow-soap, mastic, subcarbonate of potash, Chinese or table-varnish, and lampblack; the varnish being the principal ingredient. The materials are incorporated in a close vessel over a fire, and when prepared, are cast into moulds. The substance taken from the moulds forms a chalk, which may be pointed like a pencil, or it may be dissolved in water to form an ink. Hullmandel recommends an ink composed of the following ingredients:—2 ounces tallow-candle, 2 ounces virgin-wax, 2 ounces shell-lac, 2 ounces common soap, and lampblack enough to bring it to the colour required. This composition is prepared and incorporated as the preceding. As it is more difficult to work with chalks than with inks, greater care is required in the preparation of the former; hence the proportions of the mixture may be varied so as to produce a mass sufficiently firm, without being dry, and also without having a tendency to clog to the stone. The ink used by the printer is generally composed of burnt oil or varnish, and lampblack, with a small proportion of indigo to bring up the colour.

The drawings, we have said, are either executed at once on the stone, or are taken from transfer paper. In the former case, the drawing is reversed; in the latter, it is done in the natural order, and appears reversed when transferred to the stone. In either case, the drawings are made by the pencil of chalk, or by ink and a fine pen or camel-hair pencil. 'To render the lithographic process intelligible'—we quote the 'Penny Cyclopaedia'—'let it be supposed that the artist now completes a drawing with the chemical chalk just described, upon a grained-stone. If, while in this state, a sponge filled with water were passed over the face of the stone, the drawing would wash out, the chalk with which it is made being, as we have seen, soluble in water, by reason of the soap which it contains. Before, therefore, it is capable of yielding impressions, a weak solution of nitrous acid is poured over it, which unites with and neutralises the alkali or soap contained in the chalk, and renders it insoluble in water. After this, the usual course is to float a solution of gum over the whole face of the stone; and when this is removed, if a sponge and water be applied to its surface, as before supposed, the drawing is found to be no longer removable, because the chalk with which it is executed is now no longer soluble in water. In this state the work is ready for the printer, who obtains impressions by the following process:—Having thrown with the ends of his fingers a few drops of water on the stone, and spread them with a sponge, so as to wet, or rather damp, the whole surface equally, the printer finds that the water has been imbibed by the stone only on those parts not occupied by the drawing, which, being greasy, repels the water, and remains dry. A roller properly covered with printing-ink is now passed over the whole stone, which will not even be soiled where it is wet, from the antipathy of oil and water. But the parts occupied by the drawing being, as we have seen, dry and greasy, have an affinity for the printing-ink, which therefore passes from the roller, and attaches itself to the drawing. In this state it is said to be charged or rolled in. Damped paper is then put over it, and the whole being passed through a press, the printing-ink is transferred from the stone to the paper, and this constitutes the impression. By repeating in this manner the operations of damping the stone and rolling in the drawing, an almost unlimited number of impressions may be obtained. Now, as we have said, the modes of lithography are various, but the illustration just given will explain the principle of them all. It consists in the mutual antipathy of oil and water, and the affinity which the stone has for both—that is, in its power of imbibing either with equal avidity.' The art, in whichever way pursued, requires great delicacy and dexterity. In drawing on the stone, the slightest mark of the hand will fasten on the surface, and appear in the impression. The execution of the impression in an

equally clear and dark manner is evidently a matter of difficult accomplishment, there being nothing more common than to see lithographic impressions light at one part and dark at the other. One of the chief disturbing causes is variation of temperature; and it is always prudent to make a few trials before proceeding to regular work; as the stone and ink which worked well in the morning, may in the afternoon produce nothing save intolerable blotches.

The process of printing differs from that of letter-press or copperplates. The stone, properly inked, and with paper over it, lies in a box on the table of the press, covered by a piece of leather (*l*), and is drawn beneath a hard edge or scraper (*s*), the mechanism being assisted by a lever power (*l*), as is shown in the accompanying figure. As in other kinds of printing, it is

necessary that the pressure be equally distributed; and for that purpose the edge of the scraper requires to be smooth and true, and the leather of uniform thickness.

*Etchings upon stone* are executed much in the same way as etchings upon other material. The stone having been previously polished, is washed in a solution of acid and water, and dried; a very small quantity of gum-water and black is laid on the stone with a rag, so as to form a thin coating. When this is dry, the drawing must be traced with red chalk, or taken in transfer, as the case may be, and executed with etching-needles. It must be remembered that these lines or scratches, which of course appear white, will seem much thicker when filled with printing-ink; this arises from an optical deception, proceeding from their change of colour from white to black. Great care must be taken not to breathe on the stone, as this would dissolve the coating of gum. When the etching is finished, the entire surface of the stone must be rubbed with a rag and linseed-oil, and afterwards the whole coating must be washed off with water. These etchings may be printed either with the roller, or, like copper-plates, with rags.

As an art, lithography has steadily worked itself into favour, partly on account of its cheapness and facility of operation, and partly owing to the numerous modes in which it may be applied. It is true that it can never equal the finer styles of engraving, but for a thousand ordinary purposes it affords a ready and not inelegant substitute. All those specimens of penmanship now so common in cards and circulars, of cheap maps and plans, of chalk-drawings, &c. are the products of the lithographic press; and so also those fancy placards, book-covers, and the like, which we find in various coloured inks and in gold and silver bronzes. The facility with which transfers from drawings, from letter-press, and from engravings, can be worked at the lithographic press, is another of the peculiar advantages of the art; thus increasing impressions without limit from one engraving. In fine, it is not too much to assert that, but for the invention of Seneffelder, the greater proportion of the appliances of calligraphy, drawing, and ornamental embellishment now so common, could never have been called into existence.

ZINCOGRAPHY.

We may here briefly allude to this art, as it is similar in principle to lithography—the surface of the

plates of zinc on which it is executed being bit away, leaving the design prominent in relief. A well-executed zincograph is little inferior to a lithograph; but though the process is simple and the material cheap, there are certain disadvantages inseparably connected with such a soft and brittle metal, that are likely ever to prevent its general adoption.

PHOTOGRAPHY.

The art of photography, or the method by which pictures or impressions of objects can be produced by the action of light,\* is comparatively of recent origin, and consists mainly of two separate and distinct processes—one of which is of French, and the other of English invention.

It is scarcely possible to decide to which nation the merit of priority is due, for both discoveries were made about the same time; and the announcement was almost simultaneous in France and England, that the beautiful but hitherto fleeting images of the camera-obscura could be fixed and retained in all their delicacy and truth, and had actually been presented as permanent pictures.

The French art depends in principle upon a fact scarcely known until this discovery, that the chemical action of light upon some bodies imparts to them an increased power of condensing certain vapours on their surface. Thus if light be allowed to fall upon part of a polished plate of silver which has been exposed to the fumes of iodine until it has acquired a coating of that substance, and the plate be then placed in the vapour of mercury, the mercurial vapour will be deposited upon that part of the plate where the light has fallen, and will cause a dimness or white appearance, forming a strong contrast with the remainder of the polished surface. If the picture of a camera-obscura be allowed to rest a sufficient time upon such a plate, it can be made visible upon it in a similar manner. The brightest parts of the picture will be shown by the greatest whitening effect of the mercury, as it is condensed most copiously where the action of the light has been strongest: intermediate tints will be brought out by degrees of whiteness varying according to the amount of light, while deep shadows or dark objects will be marked by the black or resplendent surface of the metal which remains untarnished.

The English sister art, though more difficult in practice, is apparently simpler in theory. It depends upon the blackening effect of light upon certain salts of silver spread upon common writing-paper. In the camera-obscura, when properly managed, the light part of the picture makes a dark impression upon the prepared paper, the degree of darkness varying in intensity with the amount of light. It thus happens that the picture, unlike the impression made by mercurial vapour upon a silver-plate, is in shade the reverse of the object before the camera, and it has been styled a *negative* impression. At first sight this appears to be a defect, but it is, in reality, a great advantage; for it gives to this branch of photography the power of multiplying its impressions indefinitely. The negative picture, preserved from the further action of light, or *fixed*, in photographic language, is placed above a sheet of paper prepared by an easier though similar process; and being exposed to the direct light of the sun, it soon gives upon the paper below a reverse copy of itself, in which the lights and shades are the same as in the object originally depicted. This has been called a positive picture, and they can be produced in any number from a single negative.

In all these pictures it will be observed that they have one great defect, inasmuch as the actual colour of

\* The term Photography is derived from two Greek words—*phos*, *photos*, light, and *graphia*, to write or draw; hence also *phototype*. The synonymous terms Heliography, from *helios*, the sun, and *graphia*—and Photogenic Drawing, from *photos* and *gignomai*, I generate, are occasionally, but less frequently, used.

## PHOTOGRAPHY.

the object is not given—they exhibit light and shade only; and although attempts have been made, with some degree of success, to give variety of tints to a chemically-prepared surface by the solar ray divided into its primitive colours by a prism, and even by coloured pictures in the camera-obscura, we fear it is highly improbable, from the very principles of the art, that a coloured object can ever be depicted in its natural aspect. Still, the sun-pictures are very beautiful, and no less surprise and delight by their remarkable minuteness and fidelity. In the following description of the photographic arts, which, from its brevity, will admit of little notice of their history or scientific principles, we shall chiefly attempt to supply a practical guide to the artist; and although many new processes have been proposed, we shall not advert to them, as the original arts, though now somewhat modified and altered, are still unequalled in the perfection of their results.

In the first place, the photographer should know that the sun's ray—the active agent in his hands—is not a simple element, but a compound of several parts. When it is made to pass through a triangular glass instrument called a prism, it undergoes a bending or refraction from its straight course; and as its elements are not all equally refracted, they can be exhibited apart from each other by receiving the dissected beam upon any reflecting surface. The white ray of light is thus divided into red, orange, yellow, green, blue, indigo, and violet rays—those colours, namely, with which we are so familiar in the rainbow. Of these, the red ray is the least refracted, and the violet the most.

In addition to the visible coloured rays, it is possible to detect at least two other elements of the original ray which have been also unequally refracted: these are heat and the power of chemical action. The heat is found to be greatest in the neighbourhood of the red, or least refrangible, and it diminishes rapidly towards the more refrangible rays; while the power of causing chemical action is greatest near the blue and violet, and diminishes as rapidly towards the red. It thus happens that a surface reflecting red or orange gives little of the chemically-acting element; while a blue or violet colour abounds in it. If the light is transmitted through a coloured medium, it obeys the same law. Red, by obstructing the blue and other rays, obstructs much also of the chemical power; while a blue medium allows it to pass freely.

The camera-obscura, which is so essential to the photographer, has been already described under OPTICS (No. 16); and it is sufficient to state at present, that for photography any kind of instrument may be used: from a common spectacle-glass, fixed in a hole in the end of a box of the simplest construction, to the more expensive apparatus made with one or more achromatic lenses by an expert optician. The valuable properties for this art are sharpness or minuteness of the image, with a large admission of light—that is, a bright, as well as a clearly-defined picture; and these can only be obtained by the use of carefully-made lenses, corrected for the imperfections of the ordinary magnifying-glass. If a common lens or spectacle-glass be employed, the light should be admitted through a very small aperture or *diaphragm* in front of it; and whoever uses such an instrument, should recollect that the chemical rays of light which produce the photographic picture are more refrangible than the principal light rays, and he should accordingly place his sensitive plate or paper a little nearer the lens than the sharpest visible image. This distance can be found by a few trials; and a tolerable picture may thus be obtained by a very inexpensive instrument. Where success is more desirable than economy, a camera should be procured which has been adapted for this art by a good optician; and they are now manufactured with glasses corrected for the defects of the common lens, as carefully as in the telescope, and provided with all the means for securing the best focus, and for introducing the prepared plate or paper so as to correspond with it. The following diagram represents the construction in common use. A is

a sliding tube in front, by which the lens can be adjusted to the proper focal distance; the other end of the box is provided with grooves, so as to admit a thin wooden frame, or pane of glass at will; B is one of

those slips or frames for receiving and inserting the prepared plate or paper.

In the practical working of this instrument, when the object to be taken is immovable—as a building, or a landscape—a very small aperture should be used, whereby greater sharpness is given to the picture; but if the light is feeble, or rapidity is of consequence—as in the taking of portraits—the aperture should be as large as is consistent with moderate distinctness. Some cameras are provided with a piece of plate glass, on which the sensitive paper is laid; and it is thereby supposed that it can be more accurately placed in the focus. Excellent cameras can be obtained on the continent from Voigtländer of Vienna, Graff of Berlin, and Chevallier and Lerebours of Paris. In this country, the best cameras we have met with have been made by Mr Thomas Davidson of Edinburgh.

### THE DAGUERRETYPE.

The method of fixing the images of the camera-obscura upon metallic plates is due to M. Daguerre, a painter in Paris, from whom the art takes its name. It was discovered by him while engaged in a series of experiments, at one time carried on along with M. Niepce of Chalons, a gentleman who had even attained some success by another but very inferior process before he became acquainted with the experiments of his partner. It was divulged by Daguerre in 1839. Since that time the art has been simplified, and rendered greatly more rapid by the employment of a substance not known to Daguerre; yet the beauty of the original pictures of fixed objects made by him has not yet been surpassed. It may be divided into the following stages or operations:—Polishing the plate; giving the sensibility to light; taking the impression; rendering it visible by mercury; removing the iodine, &c.; and lastly, fixing the impression.

For these processes certain chemicals and articles of apparatus are requisite; namely—highly-polished plates of silverised copper: they are manufactured at Sheffield and Birmingham, as well as imported from France. Three or more boards of half-inch deal, 2 feet in length, and 4 or 5 inches broad, covered on one side with cotton velvet, applied above a layer of cloth or flannel: these are termed buffs, and are for polishing the plates; one is dusted with finely-powdered tripoli or rotstone, and another with calcined lampblack, placed in a muslin bag. Two deep glass troughs, a little larger than the plates to be used: they are enclosed in wooden frames, and have carefully-ground plate-glass covers: one of them is charged with a layer of powdered iodine, mixed with arrowroot, and the other with a preparation of bromine, made by either of the following methods:—1st, One part of a saturated solution of iodine in spirit of wine is added to six or eight parts of water, a saturated solution of bromine in water is then poured into it, until the whole becomes of the colour of Madeira wine; and a small quantity of this liquid is poured into the glass when required. 2d, The bottom of the glass is covered to the depth of a quarter of an inch or more with arrowroot, moistened with water, acidulated with ten or twelve drops of sulphuric acid, eight or ten drops of bromine being mixed with it when required, and renewed as often as the reddish-brown colour becomes faint by the evaporation of the bromine. A camera-obscura, provided with the necessary frames or slides for receiving the

prepared plates. A deep box, with an iron cup at the bottom, holding two or three ounces of mercury, and with a lid opening at the top of the box, and slanting to its hinges, with an inclination of 45 degrees. A solution of one part of hyposulphite of soda in ten parts of water. A solution of chloride of gold, &c. made as follows:—thirty grains of hyposulphite of soda are dissolved in twenty ounces of distilled water, to which is added, drop by drop, a solution of ten grains of chloride of gold in a small quantity of pure water, the mixture being well stirred all the while.\*

Having, if necessary, cut the plate to the size of the camera slide by a sharp-pointed knife, or pair of strong scissors, it is polished by briskly rubbing it upon the polishing buff, beginning with that which has been dusted with the rotstone, then on that which is covered with lampblack, and finishing with the clean velvet.

When it is perfectly bright and resplendent, it is placed (in a nearly-darkened room) over the glass containing iodine, where, in a few minutes, it receives a coating from the iodine fumes, which should appear of a golden-yellow colour over the whole surface. Care must be taken to avoid too long exposure to the iodine, by which the yellow will speedily pass into purple, when it will be necessary to repolish the plate. In this state it may be used for taking bright and stationary objects; but an exposure of several minutes in the camera is necessary. When rapidity is required, the plate, after attaining the golden-yellow colour, is transferred from the iodine box to the other dish containing the bromine preparation, where it speedily receives a coating from the bromine vapour, and assumes a violet hue. It is now much more sensitive to light, and the amount of bromine may be so managed that a picture can be taken in a single second. Some manipulators, after giving this coating of bromine, replace the plate for an instant over the iodine, and thereby imagine they prevent spots, and produce pictures of a finer tone.

In some cases it is expedient to carry the first application of iodine as far as a reddish hue, and then to apply the bromine until a blue shade is produced. Even bromine alone may be used; and this gives the greatest sensitiveness of all. In practice, however, this extreme sensitiveness is not desirable, from the difficulty of catching the exact time to stop the action in the camera, when the whole exposure is so short. If it is an instant too long, the gradation of shades is lost, and the whole picture may become of a uniform white when subjected to the subsequent process: it is then said to be solarised. In reality, the exact quantities of the sensitive coatings, and the time for exposure in the camera, are only to be learned by practice. They vary according to the clearness of the sky, and the colour of the object to be taken: so much so, indeed, that even the most expert Daguerreotypists are often obliged to make a few experimental trials in commencing their operations for the day. In practice, the best portraits are usually taken when the sensitiveness is such that eight or ten seconds are required to make the impression; and this degree is attained with a good camera, when the plate, after being iodised to a yellow, has been brought to a violet by the bromine.

The plate, as soon as it is made sensitive, is placed in the frame or slide by which it is carried to, and exposed in the camera-obscure; and when the impression is taken, it is again removed to a dark room, where it is fixed, by an appropriate contrivance, on the inside of the lid of the mercury-box, so as to rest with its prepared side towards the mercury, and sloping at an angle of 45 degrees. The mercury being now heated by a spirit-lamp, the vapour rises, and the image is gradually unfolded; when it is sufficiently distinct (care being taken that it is not too much mercurialised, by which its whole surface would be dimmed), it is laid in a plate or shallow trough, and the hyposulphite solution is poured upon it, to dissolve off the iodine

coating. This should take place very rapidly, and the solution may be poured back into the bottle through a filter for further use.

The picture is now partially fixed, and it would remain for a long time unchanged if protected by glass. It can be remarkably improved, as well as rendered more permanent, by a process discovered by M. Fizeau, by which metallic gold is precipitated upon the plate, and uniting with the molecules of mercury, augments their brightness, and consequently the strength of the picture. The process of M. Fizeau is as follows:—The plate taken from the solution of hyposulphite of soda, and very carefully washed by pouring a stream of water over its surface, is placed upon a horizontal support, and covered with as much of the gold solution as will remain upon it. The flame of a strong spirit-lamp being now applied, the improvement is seen to take place rather suddenly, just as the liquid begins to boil. If this is carried too far, a film of metal will start from some part of the surface of the picture, and the whole will come off so easily that the impression is utterly spoiled. The plate is now quickly thrown into water; water is freely poured over its surface; and it is dried by holding it with forceps, in a slanting position, over the flame of a spirit-lamp, so placed that the drying shall begin at the top, and pass rapidly downwards, the last drops of water being blown off by the mouth.

The picture will now admit of being coloured, if it be thought desirable, and it is done very simply by dusting or laying over it any metallic pigment of the required tints. When the picture is unsatisfactory, it should not be subjected to the fixing process, but be carefully repolished on the velvet buff; and if it be much soiled or scratched, it must undergo a previous friction with tripoli powder and oil, and be strongly heated by a spirit-lamp. The same plate may thus be made to undergo many trials.

The finished picture must be protected in a glass frame.

#### THE TALBOTYPE.

The other branch of the photographic art, by which the pictures of the camera are retained upon common writing-paper, is the discovery of Mr Fox Talbot, and was styled by him the Calotype (*Gr. kalos, beautiful*). Depending in principle upon the blackening effect of light upon the salts of silver—a fact which had long been known to chemists—the idea of taking impressions of objects by this means was not new, although no one had met with much success in its practice. As early as 1802, Mr Wedgwood published a method of making profiles by the action of light upon paper or leather which had been coated with a solution of nitrate of silver; but his experiments were attended with little success, and he was unable to preserve his pictures from the further action of light after he had made them. Mr Talbot himself, in a process communicated to the Royal Society on the 21st February 1839, so far anticipated his own greater discovery; another step towards it was soon after made by the Rev. J. Reade, who employed the infusion of the gall-nut to increase the sensitiveness of the argentine preparation; and finally, Mr Talbot divulged and patented the Calotype in February 1841.

It is this art, now usually called the Talbotype, which we propose to describe. It has been improved in some respects with the experience of eight or nine years, and it now differs materially from the original patented process in its details, although in principle it is still the same. The substances employed in it are—nitrate of silver, iodide of potassium, commonly called hydriodate of potass, gallic acid, pure and crystallisable acetic acid, and hyposulphite of soda—all of which may be obtained in a state of sufficient purity at the shop of any respectable chemist. It is very much otherwise, however, with the paper on which the picture is to be taken; and we believe that many incipient photographers have thrown up the art in despair, because they did not happen to use good paper, and were not

\* The above-described apparatus may be seen or obtained at Watson's, cabinet-maker, Earthen Mound, Edinburgh.

## PHOTOGRAPHY.

aware that their want of success could be owing to this cause. It is to be hoped that ere long the trials, now in the hands of more than one experimentalist, will result in the use of glass plates, or some fabric more perfect than any paper at present in use. The desirable qualities in paper are a smooth, fine, and uniform texture, with a sizing so strong, that the paper is not bibulous when put into water, and especially the absence of all chemicals, sometimes employed in its manufacture. These requisites have usually been found, in a tolerable degree, in a yellow post, bearing the watermark, 'Whitman, Turkey-mill,' and better in old than in new specimens. Until some fabric of better qualities is produced, the photographer should examine all the varieties of paper he can find, in which he will be assisted by dipping them in water; and having selected and marked the most perfect specimens, he should subject them to a comparative trial of the whole process, to discover the best. The paper, before it is subjected to any of the preparations, should be cut into pieces a little less than the camera slide, as it expands when wet; and being marked to distinguish the side, each portion is to be coated with iodide of silver, by the following process proposed by Mr William Furlong in 1844:—25 grains of nitrate of silver are dissolved in one ounce of distilled water, to which about  $3\frac{1}{2}$  drachms of iodide of potassium is then added, and shaken until the copious yellow precipitate is re-dissolved. This solution is to be freely brushed over the marked side of the paper by a clean and dry camel-hair pencil, or with a little cotton wool. The paper is then allowed to dry spontaneously, or at a fire; and when dry, it is immersed in a basin of tepid (not hot) water, when it speedily assumes a yellow colour by the precipitation of the iodide of silver into its texture. It may be placed in cold water, but then the yellow colour is longer in appearing. It is now to be well washed in several changes of water, or allowed to lie in it for an hour or two, when it may be again dried on clean blotting-paper, or at a fire, or pinned up to dry spontaneously. It is called by photographers iodised paper, and it may be kept for years. The following solutions are required for the next steps of the process, which should be conducted by the light of a candle, or in a room from which daylight is nearly excluded by a red curtain:—1. A saturated solution of gallic acid in distilled water; 2. A solution of 50 grains of nitrate of silver in 1 ounce of distilled water, to which is added 2 drachms of pure crystallisable acetic acid; 3. The preceding solution diluted with eight times its bulk of distilled water.

When a picture is to be taken, the dilute solution No. 3 is freely brushed over the surface of the iodised paper by means of a camel-hair pencil, of the kind called 'swan quill,' or by a bit of cotton wool, which is more economical; and by the use of a fresh quantity for every application, is *always clean*. The superfluous solution, after about half a minute, is blotted off by one or more applications of clean white blotting-paper; and the paper, now sensitive to light, is carefully placed in the slide, to be conveyed to the camera-obscura. When the operation in the camera is concluded—which will occupy from twenty seconds to three or four minutes—the slide containing the paper is reconveyed to the darkened apartment; and a mixture being made of equal parts of solutions Nos. 1 and 2, it is very freely brushed over the face of the paper as before, and allowed to remain upon it so as to be wet, until the picture, which soon appears, is sufficiently strong, or till the whole surface begins to turn brown. It is now to be immersed in clean water, where it may remain excluded from light for many hours, until it is convenient to fix the impression.

The above process admits of some variations: for example, a few drops of the gallic-acid solution may be mixed with the dilute solution No. 3, for application to the iodised paper, and it will make the impression come out sooner. If the sensitive paper must be kept some time, as an hour or two, before it can be

used, then the solution No. 3 may be made more dilute, even to three times the extent directed, with advantage. If the picture unfolds itself of a reddish hue, more gallic acid should be immediately applied; and if the whole surface darkens before the picture is sufficiently strong, it is often an indication that there is a want of acetic acid in the sensitive solution No. 3. In this case an additional quantity must be added; care being taken, however, not to use an excess, which impairs the sensitiveness of the paper. If the picture still appears of a dusky hue, the iodised paper should be exposed to the sun for ten minutes, which often improves it; and if, after all, a good picture cannot be obtained, the fault in all probability lies in the paper itself. Some artists do not use the dilute solution No. 3, but make the paper sensitive by No. 2 undiluted, and bring out the picture by No. 1 alone.

The weather most suitable for the photographer is a bright day, with a clear blue sky and sunshine, if the object be to take buildings or views; for portrait-taking, however, a clear day without sunshine is preferable. Great success cannot be attained in foggy weather, or in the smoky atmosphere of a large town; and some coloured objects, particularly such as are of a reddish or tawny hue, always make a comparatively feeble impression. We were once long puzzled on finding the portrait of an individual invariably covered with blotches corresponding to white spots on the negative, until at last it was seen to depend upon a multitude of freckles, scarcely otherwise perceptible! It is for the same reason that many paintings cannot be well copied by the Talbotype; the reddish or yellow colours, which may be the brightest parts of the picture, reflect the chemical ray feebly, and are dark in the finished positive, while every tint of blue which reflects it strongly is in the same degree too bright.

The negative, after being immersed in water for an hour, to be freed from all undecomposed nitrate of silver, may be preserved from the further action of light, or fixed, by simply wetting it thoroughly with the solution of hyposulphite of soda, when it is to be again immersed for some hours in clean water; but it may be fixed, and the yellow coating of iodide of silver removed by one operation: thus—place it in a common earthenware dish of sufficient size, pour over it a few ounces of the solution of hyposulphite of soda, and then heat the dish over a fire until the yellow colour is removed, which will happen before the liquid approaches a boiling temperature. Another negative may be then whitened by the same solution. The hyposulphite of soda should now be removed, by placing the negative in water for twelve hours, or by repeated washing. When the impression is not too faint, the negative may be improved by waxing it, which is accomplished by placing it on blotting-paper over any surface sufficiently hot to cause the wax to melt when rubbed upon the picture—an excess of wax, if any, being wiped off with blotting-paper. Black spots on any part of a negative may be obliterated by touching them with a solution of 20 grains of cyanuret of potassium in 1 drachm of water, care being taken to prevent it from spreading. The same solution is useful for removing the black stains from the fingers, so characteristic of the Talbotypist.

Positive impressions are obtained from the finished negative in the following manner:—To a solution of 50 grains of nitrate of silver, in 1 ounce of distilled water, add strong liquid ammonia until the precipitate which is at first formed is re-dissolved. This liquid will form a sufficiently sensitive coating on some kinds of paper, which may be discovered by trial. It acts well on a thick post by *Nash*. Brush it freely over the paper; dry it thoroughly, either before a fire, or slowly in a room nearly dark; and place it upon a flat board, which is covered with a layer of cloth or several plies of paper. Lay the negative over it with the picture-side downwards, and cover the whole with a thick glass plate, screwed down to keep the negative closely applied. When now exposed to

daylight or sunshine, the light passes through the negative, which gives a reverse impression of itself on the paper below, the lights and shades of the picture being now in their natural state. A convenient positive apparatus may be made by fixing the plate-glass in a frame, which is hinged upon the flat board, and secured by a catch or buckle. Some specimens of paper do not blacken readily with the above preparation, and in that case the paper must be salted, by dipping it in a solution of a teaspoonful of common salt in half a gallon of water. When dry, it will be found to answer. A solution of nitrate of silver alone may be used with salted paper; and by varying the strength of the nitrate of silver from 40 or 50 grains to 80 or 100 for each ounce of water, and exposing the positive frame to diffused daylight, or to strong sunshine, a variety of tints may be obtained for the positive pictures. The time necessary to make a positive impression varies with the transparency of the negative and the amount of light. In bright sunshine, a light waxed negative will be copied in two or three minutes; while, in other circumstances, a whole day may be required. It is advisable to make the positive rather too dark at first, as it may be revived to any degree of brightness by the fixing process it has afterwards to undergo. It is now immersed in water for an hour, or washed in a weak solution of salt and water, to decompose any remaining nitrate of silver, and then laid in a dish in the solution of hyposulphite of soda. If the impression is not too dark, it should be soon removed; but if otherwise, it may be allowed to remain in it for some hours, or even a day or two, until it be reduced to the proper shade. The hyposulphite must now be carefully removed, by allowing the positive to remain not less than twelve hours in water, frequently changed, and, finally, it should be immersed in hot water for half an hour, to insure the complete removal of the salt. If this is not done, the impression may become gradually weakened after many months. It may now, if desirable, be fixed on Bristol-board, by means of isinglas, gum water, or weak glue.

The positive process may be employed to copy lace, leaves of plants, manuscript, or printing on one side; etchings, engravings, or drawings, the first impression being of course a negative. A collection of valuable etchings may thus be copied without injury, and from each of the negative impressions so obtained any number of fac-similes of the original may be multiplied at a very trifling cost.

It is a singular fact in the history of photography, that the first methods—namely, these which we have now described in detail—should have been given to the world almost perfect from their origin. Discoveries so remarkable could not fail to attract many experimenters into the same field; and the chemical action of light has now been minutely investigated in its relations to numerous substances. Such inquiries have naturally produced many new processes for the delineation of the images of the camera-obscura, as well as the less delicate methods by superposition; yet none of these, as far as we know, has rivalled its progenitor either in the certainty or perfection of its results. It seems, therefore, sufficient to mention, that most of the new processes, as well as much information on the science of photography, are to be found in a series of papers by Sir John Herschel in the 'Philosophical Transactions of the Royal Society of London,' commencing in 1840, and in a work entitled 'Researches on Light,' by Mr Robert Hunt.—(Longman and Co., London.)

The amateur and professional artists employ almost exclusively the Daguerreotype and Talbotype, to the comparative qualities of which we shall now shortly allude, for the guidance of those who would attempt the practice of the art, but are uncertain to which process they should give the preference. The peculiar characteristics of the Daguerreotype picture are its extreme delicacy and minuteness, which are sometimes even too minute for the unassisted eye to appreciate. By the aid of a magnifying-glass, objects have actually

been seen most faithfully depicted, which, in the original view, required the use of a telescope to be observed. This extraordinary finish of detail, causing no detriment to, but rather adding to the harmony of the general effect, imparts an inexpressible charm to these pictures; for they actually seem to be the reality itself, and not an imitation.

The portraits from the life which were first taken by this process had many faults: their hue was pale and leaden, and the length of time required for an impression was such that no features could retain their expression: the movements inseparable from a long sitting impaired also the sharpness of the form and outlines; and though still extraordinary in this respect, the picture had always a stiff and death-like aspect. Now, however, by the increased rapidity of the process, by which a sitting of a few seconds only is necessary, and that in a light which can be borne without effort or pain, the Daguerreotype portrait seems to be the most perfect approach to the living reality which can be imagined—the passing smile, the very softness of the skin of youth, are faithfully recorded.

In the Talbotype picture the effect is different, and it has a value also peculiar to itself. Its delicacy in a landscape or building is far inferior to the Daguerreotype, yet still the impression is as minute as paper can receive; and while the tone can be varied to almost any shade of reddish-brown or black, a good impression, once obtained, can be multiplied without limit, and at a cost which enables the amateur to distribute his works as widely as he may desire. For this last reason also the Talbotype is continually available, and affords a perpetual source of amusement.

It has been said that a common incident, graphically narrated, excites as great an interest as a wonderful adventure; and so also do we derive pleasure from the graphic delineation which the Talbotype gives us of even a common object: a bush, a stone, or an effect of light, may exhibit as much of the beautiful and picturesque as a study of much pretension. To the painter, such subjects are invaluable—they show him how nature should be viewed; and we could name those in the highest rank in that profession who have taken lessons in this school, and have not been ashamed to avow their master.

Many portraits by the Talbotype are not good or pleasing likenesses, from imperfection in the paper employed, or from a look of distress, or total want of animation, sometimes unavoidable in a process still too long. Individuals whose habitual appearance depends more on the expression than the form of their features, may also fail to obtain a good resemblance. But many people dislike these pictures from inability to appreciate their beauties. A glaring daub may be more prized by the vulgar than a valuable painting by the hand of a master; and the Talbotype of rare beauty is sometimes despised because it has not the brilliant colouring or the open eyes of a commonplace portrait or miniature. It is worthy of remark, that those who are acquainted with the works of Titian, Rubens, Rembrandt, and other great painters, are no less surprised than delighted to trace the resemblance in their pictures to the impressions of the Talbotype, proving in this manner the true observation of nature by the ancient masters. And when the skill of the artist in arranging the subjects is combined with dexterity in the photographic manipulation, no painter's hand can compete with these productions of nature herself in the fidelity and power of their expression. We have seen Talbotypes produced jointly by the late Mr Robert Adamson and Mr D. O. Hill of Edinburgh which warrant these remarks, and have obtained this tribute from the greatest among the painters of the present day.

Specimens of this art have been published by the inventor himself in a work entitled 'The Pencil of Nature' (Longman, Brown, and Co., London); and may be obtained from Messrs Hanneman and Malone, Regent Street, London; and from Mr Alexander Hill, Princes Street, Edinburgh.

## MUSIC.

It is the object of the following pages to exhibit such a view of the principles and practice of music as may be calculated for popular information. The path to musical knowledge has for the most part been rendered rugged and toilsome by the interposition of many needless difficulties. Things really plain and simple have been invested with an air of mystery; and the great principles of the art, though in themselves easily explained, and easily understood, have been buried beneath a mass of useless technicalities. The conviction that this is the case has sometimes led to the opposite extreme; and the study of music has been apparently simplified by short-hand methods and mechanical contrivances, devised to diminish the labour of reflection and memory. But there is no 'royal road' to music any more than to mathematics. Skill in its practice is to be gained only by a clear understanding of its principles. All that the instructor can do is to divest those principles of unnecessary obscurity, and to present the rules of practice in their simplest and most comprehensive form.

The musical artist, whether as a composer, a singer, or an instrumental performer, requires a very different degree of knowledge and skill from the amateur, who cultivates the art as an elegant accomplishment and as a refined and intellectual pastime—an innocent and salutary relaxation from the severer cares and occupations of life. In this point of view, there is no station or degree of society in which music may not be cultivated with advantage. And the experience of the present day has shown, and is showing more and more, that even the classes who earn their daily bread by the sweat of their brow, may find in music a recreation within their reach, full of innocent enjoyment, and pregnant with moral and social benefits. It has been found that the highest pleasures which it can impart—pleasures derived from the knowledge of its noblest productions—are accessible to the humblest as well as the highest; and that it is to the toil-worn artificer and labourer that music dispenses its best and dearest blessings.

Those, however, whatever may be their station in society, who are to derive such benefits from music, must acquire a knowledge of it *as an art*, whose principles and rules afford exercise to the intellect, and whose lofty and beautiful productions exalt and purify the mind. Many tribes, in a very rude state of society, exhibit much sensibility to music, and derive much pleasure from the simple strains in which, taught by nature alone, they give expression to their feelings; and there is no doubt that even to their untutored minds music, such as they possess, is a source of much higher and better enjoyment than the mere gratification of sense. But it is only, we repeat, where music has become an art, and where its exercise is invested with the dignity of an intellectual pursuit, that its effects as an instrument of civilisation and moral improvement become evident and striking.

It is of course to the more wealthy and educated classes of society that the attainment of scientific knowledge and technical skill in music has been hitherto confined. At this day, even these classes in this country have little to boast of in this respect; much less, indeed, than they had two or three centuries ago. In the sixteenth and seventeenth centuries, the music chiefly cultivated in England consisted of *vocal harmony*, and the performance of the inimitable *madrigals* of the Italian and English masters of that age was regarded as a most elegant pastime, in which every one who had pretensions to the habits and manners of good society was supposed capable of participating. Every musical student, as far as his means and opportunities permit, ought to follow the example set in these times, and study both the theory and practice of harmony; for it is impossible either to acquire a respectable

degree of proficiency in the practice of music, or to derive real pleasure from it as a liberal and intellectual pursuit, without that expansion of mind which is derived from a knowledge of its principles.

This study ought to be conjoined with the practice of singing, or performance on some instrument. Great facilities will be afforded by being able to play ever so little on the pianoforte; to do which, in so far as to realise to the ear the effect of successions of chords and combinations of harmony, is a matter of no difficult attainment. People will prosecute the study in different ways, and carry it different lengths, according to their different dispositions, opportunities, and views. But we may say in general that a familiarity with the principles which we shall attempt to develop, combined with moderate skill and readiness in singing or playing on an instrument, will produce that enlargement of view which is requisite for the full comprehension and enjoyment of the noblest productions of the art. We may add, that the study of harmony will be more pleasantly and successfully followed as a domestic and social pastime than as a solitary pursuit. Members of a family may follow it together; or a circle of friends and companions may form themselves into a little class for the purpose. Supposing them to have profited by the methods of instruction, now so easily accessible, so as to be able to sing from the notes vocal passages of the simplest kind (if with a pianoforte, so much the better), they will find little difficulty in mastering the contents of the following pages.

### THE SCALE.

Music is composed of sounds produced by the human voice, or by instruments constructed for that purpose, varying in pitch according to certain fixed and determinate degrees. The gradation of these sounds, from the lowest, or most grave, to the highest, or most acute, forms what is called the *musical scale*, a scale evidently derived from nature, since, though it has been found to be more or less complete in different times and places, it is the same in its principal degrees in all parts of the world. By using the different sounds or notes of this scale in succession, in such a manner as to give pleasure to the ear, *melody* is produced; by using two or more of them at the same time, in such a manner as to be agreeable, *harmony* is formed. Melody, in its simpler forms, is immediately dictated by nature, as no people or tribe, however rude, seems ever to have been destitute of it. Harmony—though its effects, as well as those of melody, must be founded in nature—has never been found to exist unless where music has received a considerable measure of artificial culture.

The natural scale of musical sounds, though its extent is limited only by the bounds of the human voice, or of the different instruments, consists only of seven notes; for it is found that if, after singing or playing these seven notes, we continue the series, we repeat another scale similar to the first, and so on, as far as the extent of the voice or the instrument will go.

To express these sounds by means of notation, various expedients, in the progress of music, have been resorted to, which have been gradually improved, till that now in use has been adopted. It consists in drawing five parallel lines, and in placing on them, and in the spaces between them, marks representing the notes of the scale. At the same time the notes have received distinguishing names, either letters of the alphabet, or syllables used for that purpose. Thus:—

There are only seven letters, because, as already mentioned, there are only seven notes in the scale. In the above figure, the last note bears the same name as the first; and if the series of sounds is carried further, the same names will be repeated. The last of the above notes, C, being the eighth from the first, is called its *octave*; and the whole series, of which it forms the beginning and the end, is called an octave. The intermediate distances or intervals are named according to the number of notes contained in them: thus, from C to D, or G to A (counting upwards), a *second*; from C to E, a *third*; G to C, a *fourth*; D to A, a *fifth*; E to C, a *sixth*; C to B, a *seventh*; and so on between any two notes of the scale. The reason of these terms will be evident by counting, for example, from E to C, a sixth; because it contains the space occupied by E, F, G, A, B, C—six notes.

In examining the above series of sounds or octave, from C to C, it will be found that the steps of the scale are unequal; the distance between the third and fourth notes, E and F, and between the seventh and eighth, B and C, being smaller than the others. In singing the scale, this is at once felt to be the case. While, therefore, the interval between C and D, D and E, E, F and G, G and A, and A and B, is called a *tone*, the smaller interval between E and F, and between B and C, is called a *semitone*.

The scale, therefore, to whatever extent it may be carried, from the gravest note that can be produced, to the shrillest or most acute, consists of a series of octaves; and in each octave, the interval between the third note and the fourth, and between the seventh

and eighth, is a *semitone*, while the other intervals between a note and that next it are *tones*.

It is easy to perceive that the five lines (or *staff*, as it is called) above described can comprise but a small portion of the musical scale, which is of indefinite extent, and limited only by the capacities of the human voice, or of instruments. The explanations now to be given are applicable to the voice, the original musical instrument, from which all others are derived.

The voices of women and boys are more acute, higher in pitch, than those of men. If a man or a woman sing the same tune, they will, if untaught, suppose that they are singing the same notes, or in unison, whereas the one is singing an octave above the other. It is for this reason that a note and its octave are designated by the same letter or syllable.

The great divisions of the voice, then, are into the *male* and the *female*. But males, as well as females, differ in the pitch of their voice; and this difference produces a subdivision. The male voice of the highest pitch is called the *tenor*; of the lowest pitch, the *bass*. The female voice of the highest pitch is called the *treble* or *soprano*; of the lowest pitch, the *contralto*.

Persons possessed of each of these varieties of voice have, generally speaking, pretty nearly the same range or compass of notes. Each voice, at an average, may be said to contain eleven or twelve notes, some more, and some less. Were we to draw a staff of eleven lines, placing the notes upon the lines, and in the spaces between them, we could comprehend the whole extent of the ordinary vocal scale, from the lowest note of the bass to the highest note of the treble, thus:—

But it is evident that this would be cumbrous, and that the number of lines would produce confusion to the eye. It is found that five lines are generally sufficient for the extent of any one voice, by adding the simple expedient, when a note happens to go either above or below the five lines, of drawing an additional little line for that note, which is called a *leger* line. By this means the staff, when necessary, may be increased to six, seven, or more lines; but too many leger lines must be avoided, as they render the notation confused.

Five lines, therefore, are taken out of the above eleven to form a staff for any one voice; but each voice will require a different set of lines. The two great divisions of voice are the bass and the treble; for the bass we take the five lowest lines, for the treble the five highest. In order to distinguish these staves

from each other, we employ two arbitrary marks, the one for the bass, and the other for the treble; thus—

The first is called the *bass*, or F clef, because it is placed on the line which has the note F. The other is called the *treble*, or G clef, because it turns on the line which has the note G, as seen in the above eleven lines.

Of these eleven lines, the five lowest being used for the bass staff, and the five highest for the treble staff, one line remains in the middle, which is common to both, and may be represented by a leger line above the bass staff, or below the treble staff.

This is precisely the same as the above diagram of eleven lines, except that the middle note, C, is placed on a leger line instead of a line prolonged like the others.

The above are the two clefs most generally used in music; and were there no other than bass and treble voices, no other clefs would be necessary. But we have seen that there are also *tenor* and *contralto* (or *counter-tenor*) voices: the range or compass of the tenor being four or five notes higher than the bass, and the compass of the counter-tenor being about an octave higher than the bass. The *tenor* part might be written on the bass clef, but the notes would not be spread over the five lines. The lower lines and spaces

would be left empty, while the higher notes would require leger lines. The same inconvenience would arise from writing the counter-tenor part on the treble clef. Two other staves, or sets of five lines, therefore, are occasionally used for the tenor and counter-tenor parts. Both of them are distinguished by a mark called the C clef; but this mark, for the tenor, is placed on the fourth line, and, for the counter-tenor, on the third line; thus—

MUSIC.

The C, in both these staves, is the same; and it is, moreover, the C which stands on the ledger line between the treble and bass staves.

The following diagram will show the relation in which the different clefs, the treble, counter-tenor, tenor, and bass, stand to each other:—

This, we apprehend, explains itself. The notes which are perpendicular to each other express the same sound. As, for example, the middle C, according to the clef used, may be written in any of the following ways:—

will find it a useful exercise to write out these examples in as many staves as there are parts, giving to each part its proper clef.

It is requisite to observe, however, that though the above clefs are necessary for the clear and correct notation of music for different voices, yet in music printed for popular use, the use of the *tenor* and *counter-tenor* clefs is now very generally dispensed with, the parts for these voices being written in the treble clef, an octave above the real notes intended to be sung. But the learner should not neglect the knowledge of these clefs, as they are always used in music of a high class. In the examples of harmony given throughout the following pages, the treble and bass clefs only are used, the harmony, even when in four parts, being written in two staves. But the learner

TIME.  
Thus much for the notation of sounds in relation to their pitch. But musical notes are not only high and low, they are also *long* and *short*; and their relative proportions to each other in this respect are expressed by differences in the form of the notes. The longest note in modern use is represented by a circle, as in the previous examples, and is called a *semibreve*. A note of half its length is called a *minim*; a quarter, a *crotchet*; an eighth, a *quaver*; a sixteenth, a *semiquaver*; and a thirty-second, a *demisemiquaver*. They are written as under. Certain marks, called *rests*, are also used to indicate pause or silence in the music. They are represented in the subjoined table—their form and position being expressive of their duration. The simple rule respecting them is, that a rest indicates silence for so long a time as the note beside it may be sung—a *minim* rest being equal in duration to a *minim* note, and so on.

Semibreve and Rest.	Minim and Rest.	Crotchet and Rest.	Quaver and Rest.	Semiquaver and Rest.	Demisemiquaver and Rest.
---------------------	-----------------	--------------------	------------------	----------------------	--------------------------

A dot placed after a note is a mark of prolongation. A dotted semibreve is equal to three minims instead of two; a dotted minim to three crotchets; a dotted crotchet to three quavers; a dotted quaver to three semiquavers; and a dotted semiquaver to three demisemiquavers.

*Measure, or rhythm,* is one of the essential attributes of music. Everybody knows the meaning of *beating time* to a tune. By beating time, the tune or melody is divided into a number of equal parts, which in musical notation are marked by lines or bars drawn across the staff; and hence each of these divisions of the air is called a *bar*.

Each portion of the melody, comprised within the limits of a bar, is also divided into *equal* parts. Sometimes the bar is divided into *two* equal parts, and sometimes into *three*. In the former case the melody is said to be in *common time*; in the latter, in *triple time*. This division of the music is primarily intended to correspond with that measure or alternation of accented and unaccented syllables which occurs in language, particularly in poetry.

There are various kinds of *common* as well as of *triple time*. The first kind of common time consists of *one semibreve* (or shorter notes equal to one semibreve) in each bar. It is marked C; thus—

The second kind of common time consists of one *minim* (or shorter notes equal to one minim) in each bar. It is marked  $\frac{C}{2}$ ; meaning, that it contains two fourth-parts of a semibreve (or two crotchets) in a bar:—

The third kind of common time is marked  $\frac{C}{4}$ . It consists of six crotchets in a bar: but these are divided into two equal parts, each of which is equal to a *dotted minim*, or what is called a *triplet* of three crotchets.

CHAMBERS'S INFORMATION FOR THE PEOPLE.

These six crotchets are divided into two triplets by *accenting* the first note of each triplet, or sounding it a little more strongly than the others. This species of time is now rarely used.

The fourth kind of common time is marked  $\frac{6}{8}$ . It consists of six quavers in a bar, divided into two equal parts, each of which is a dotted crotchet, or a triplet of three quavers.

Triple time consists, first, of a *dotted semibreve*, divided into three equal parts, each of which is a minim, or two crotchets, or four quavers. This is now seldom used.

Secondly, of a *dotted minim*, divided into three equal parts, each of which is a crotchet, or two quavers, or four semiquavers, and marked  $\frac{3}{4}$ .

Thirdly, of a *dotted crotchet*, divided into three equal parts, and marked  $\frac{3}{8}$ .

Lastly, of *three dotted crotchets*, and marked  $\frac{9}{8}$ .

Although the dot is used for indicating the division of a note into three (instead of two) equal parts, yet it is common to divide notes into triplets without the use of the dot. Thus, in common time of a semibreve in a bar, it may be divided thus—

And in  $\frac{3}{4}$  time—

In these cases, the notation of C time is similar to  $\frac{1}{2}$ ; and  $\frac{3}{4}$  to  $\frac{3}{8}$ . When a note, without being dotted, is thus divided, the triplet is frequently marked with a small figure 3, but this is not always done.

An individual bar may have parts of different value in it; thus in common time may occur—

And in triple time—

Each of these triplets may be divided into six semiquavers.

The last kind of common time is marked  $\frac{1}{2}$ , and consists of four dotted crotchets, each of which may be divided into a triplet of three quavers. The bar of  $\frac{1}{2}$  is just two bars of  $\frac{3}{4}$  thrown into one.

DIVERSITY OF KEYS.

It has been already shown that the scale consists of a series (more or less extended) of *octaves*; and that in each octave the intervals between the third and fourth note, and between the seventh and eighth, are *semitones*; all the other intervals between two adjoining notes being *tones*. It is this inequality in the intervals which produces the tune or melody of the scale.

In singing this scale, we may begin upon any note at pleasure; and this note, whatever it may be, is called the *key-note*. But on whatever note we begin to sing the scale, we must, in order to preserve its tune or melody, place the *semitones* in the positions already mentioned—that is, between the third and fourth notes, and between the seventh and eighth. We have already exemplified the scale, as commencing on the note C. Take it now upon another note—suppose G.

But one of the intervals in this scale is not in its proper place. The interval from E to F, which (as we have

MUSIC.

seen) is a semitone, is here between the sixth and seventh, instead of being between the seventh and eighth; while the interval between the seventh and eighth is a tone, instead of being (as it ought) a semitone. The other semitone, from B to C, is in its right position. To correct this, it is only necessary to raise the pitch of the note F, so as to make it a whole tone higher than E, and consequently a semitone lower than G. A new note is thus obtained, called *F sharp*, which is distinguished by a particular mark, as under—

Again, commence the scale on the note D—

Here two of the semitones are out of their proper places, as may be seen at a glance. But we correct the position of the first semitone by raising the pitch of the note F, as in the previous example, and we correct the position of the second semitone by raising the pitch of the note C. Thus—

The mark prefixed to the last D is called a *natural*. When the pitch of a note has been raised or lowered by a sharp or a flat, this mark indicates that the note so altered is restored to its natural pitch.

By thus dividing every tone into semitones, a new scale may be formed, consisting entirely of semitones. In the first place, it may be formed by raising the pitch of each note, excepting where semitones already exist—

Or it may be formed by depressing the pitch of each note—

In both these scales, the intervals between E and F, and between B and C, being semitones at any rate, undergo no alteration.

The scale which thus proceeds entirely by semitones is called the *Chromatic* scale, to distinguish it from the natural, which is called the *Diatonic* scale.

The chromatic scale, formed by sharps, is not precisely the same as that formed by flats, as the interval called a semitone is not the exact half of a tone. But the difference is so minute as to be in some measure disregarded in practice; and on keyed instruments (the organ and pianoforte) the two chromatic scales are played in the same way; the C sharp and D flat, D sharp and E flat, &c. being considered the same sounds. But though these sounds may seem the same to the ear, it is evident, from the preceding account of the formation of the scale, that they must not be confounded in musical notation.

By the formation of the chromatic scale, we obtain twelve notes in each octave; and upon every one of these notes a scale may be formed; or, in other words, every one of these notes may be taken as a key-note. Moreover, as several of the notes appear in a double aspect, though identical in sound (as C sharp and D flat, D sharp and E flat, F sharp and G flat, G sharp and A flat, and A sharp and B flat), each of these double forms of the same note gives rise to a different scale or key, which, though consisting of the same sounds, must be differently noted. Each scale or key is distin-

guished by a *signature*, pointing out the notes which have been altered from the natural scale, by means of sharps or flats. The scale commencing on G, for example, contains one altered note, F sharp; and the signature placed at the beginning of a piece of music in the key of G, shows that wherever F occurs, it is sharp. The signature of the key of D shows that F and C, wherever they occur, are sharp. The signature of the key of F shows that the B is always flat; and so on.

Take now the note F as the key-note or foundation of a scale.

Here the first semitone is misplaced, being between the fourth and fifth, instead of the third and fourth. The other semitone is rightly placed. To correct this, it is necessary to depress the pitch of the fourth note B, in order to bring it nearer to the A; and the new note thus obtained is called *B flat*, distinguished by a mark, as under—

In this manner the learner may form a new scale on every note of the octave. In doing so, he will find that every interval of a tone may be divided into two semitones, by placing between the two notes a third note, at the distance of a semitone from each. And this third note may be obtained by raising the pitch of the lower of the two notes, or by lowering the pitch of the higher. Thus the tone between C and D may be divided into two semitones, by inserting between these notes either a C sharp or a D flat.

When the pitch of a note has been raised or lowered by a sharp or a flat, this mark indicates that the note so altered is restored to its natural pitch.

By thus dividing every tone into semitones, a new scale may be formed, consisting entirely of semitones. In the first place, it may be formed by raising the pitch of each note, excepting where semitones already exist—

Or it may be formed by depressing the pitch of each note—

In both these scales, the intervals between E and F, and between B and C, being semitones at any rate, undergo no alteration.

The scale which thus proceeds entirely by semitones is called the *Chromatic* scale, to distinguish it from the natural, which is called the *Diatonic* scale.

The chromatic scale, formed by sharps, is not precisely the same as that formed by flats, as the interval called a semitone is not the exact half of a tone. But the difference is so minute as to be in some measure disregarded in practice; and on keyed instruments (the organ and pianoforte) the two chromatic scales are played in the same way; the C sharp and D flat, D sharp and E flat, &c. being considered the same sounds. But though these sounds may seem the same to the ear, it is evident, from the preceding account of the formation of the scale, that they must not be confounded in musical notation.

The preceding signatures are in the G or treble clef. In the C, or tenor and counter-tenor, and F, or bass clef, they must vary according to the clef.

CHAMBERS'S INFORMATION FOR THE PEOPLE.

In the *sharp* keys, the series of key-notes proceeds from the natural key of C upwards by fifths. G, the fifth above C, has one sharp; D, the fifth above G, has two sharps; A, the fifth above D, has three sharps, &c. In the *flat* keys, the series of key-notes proceeds from C downwards by fifths. F, the fifth below C, has one flat; B flat, the fifth below F, has two flats; E flat, the fifth below B flat, has three flats, &c. The following are the signatures and key-notes of the different keys in common use. The key of C has no signature.

Sharp keys—

Flat keys—

From what has been said, it will appear that several of these scales, though differently noted, are played on the pianoforte with the same keys. Thus C sharp, with seven sharps at the signature, is the same as D flat, with five flats; C flat, with seven flats, is the same as B with five sharps; and F sharp, with six sharps, is the same as G flat with six flats.

The above are the principal sharp and flat keys, with the use of which it is necessary to be familiar; but there are others occasionally but rarely used. And, indeed, the series, whether of sharp or flat keys, may be carried out indefinitely.

By affixing certain syllables to the different degrees of the diatonic scale, the singing of music at sight is much facilitated. The syllables used for this purpose are—

1 2 3 4 5 6 7  
Do Re Mi Fa Sol La Si

The first, or Do, corresponding to the key-note. For example, with the signature of three sharps, Do is A; Re, B; and so on. Upon the recurrence of the key-note in its octave, Do is again used, and a second series is founded upon it. By these means a certain note of any scale is always associated with a certain syllable, and a certain interval definitely marked by the syllables at its extremities. The practising of music with syllables in this manner is called *Sol-fa-ing*.

THE MINOR SCALE.

The scale hitherto described, in which the semitones stand between the third and fourth, and between the seventh and eighth, is called the *major* scale, to distinguish it from another, called the *minor* scale.

If we commence on the sixth note of the scale already described, and ascend to its octave, without altering the natural notes, we have the minor scale. Taking A as the sixth note of the scale of C, we have—

The characteristics of this scale are, that the semitones are placed between the second and third notes, and between the fifth and sixth. In singing this scale, it will be felt that this position of the semitones gives the tune or melody a melancholy expression, which distinguishes it from the major scale.

It is, especially, the difference between the interval of the third in the two scales which is their distinguishing feature. In the major scale, as we have seen, the interval between the key-note and the third consists of two tones; in the minor scale, the interval between the key-note and third consists of a tone and semitone. The one kind of third is called a *major third*, the other a *minor third*.

The other marks which distinguish the above minor scale from a major scale—namely, the semitone between the fifth and sixth, and the whole tone between the seventh and eighth—are not always preserved. It is one of the refinements of modern music, that in rising from the seventh to the eighth, we always do so by a semitone, whether the scale be major or minor. When this is done, the sixth note of the scale is also raised

a semitone; so that the *ascending* minor scale generally stands thus—

Differing from the major scale of A with three sharps only in the circumstance that the third is minor.

The minor scale thus admits of some variety. It may be written in either of the above ways, or, while the seventh is sharpened, the sixth may remain unaltered. But the scale, whether ascending or descending, is considered as consisting of the notes given in the first example. The minor scale of A, therefore, has no signature at the clef, the sixth and seventh notes being marked with sharps only when they occur, so altered, in the course of the piece.

Every minor scale, being formed on the sixth note of a major scale, is said to be *relative* to the major scale on which it is so formed.

Thus the minor scale of A is relative to the

	major of	-	-	-	C
	The minor of	-	E	to the major of	G
	...	...	B	...	D
	...	...	F#	...	A
	...	...	C#	...	E
	...	...	G#	...	B
	...	...	D#	...	F#
	...	...	A#	...	C#
	The minor of D is relative to the major of				F
	...	G	...	...	Bb
	...	C	...	...	Eb
	...	F	...	...	Ab
	...	Bb	...	...	Db
	...	Eb	...	...	Gb
	...	Ab	...	...	Cb

The signature of every minor key is the same as that of its relative major. Thus C major and A minor have no sharp or flat at the clef; G major and E minor have one sharp; D major and B minor have two sharps; F major and D minor have one flat; B flat major and G minor have two flats; and so on.

INTERVALS OF THE SCALE.

The next object of attention ought to be the *intervals* of the diatonic scale. This scale may be called the alphabet of music; as from the various successions and combinations of these sounds the beauties of melody and harmony are derived.

The intervals of the scale are expressed by numbers, and are called the second, third, fourth, fifth, sixth, seventh, and eighth, or octave. Each of them is of different kinds.

The second is *major* and *minor*. The *minor second*, or *semitone*, is the interval between the third and fourth notes of the scale, and between the seventh and eighth. In the key of C, these intervals are—

## CHAMBERS'S INFORMATION FOR THE PEOPLE.

But with all the potency of melody, it is to Music in its form of HARMONY that we must turn for that richness and variety of which it is capable. We are therefore to consider intervals as being not only between two notes sounded successively, but between two notes sounded together. In the one case, they are intervals of melody; in the other, they are intervals of harmony. Intervals of melody are written as above, intervals of harmony as under—

SECONDS.

THIRDS.

FOURTHS. Sharp.

FIFTHS. Imperfect.

SIXTHS.

SEVENTHS.

OCTAVES.

Intervals may be inverted; that is, the lower note, by being raised an octave, may be placed uppermost; or the upper note, by being lowered an octave, may be placed undermost.

By inversion, a second is changed to a seventh, and a seventh to a second; a third is changed to a sixth, and a sixth to a third; a fourth to a fifth, and a fifth to a fourth.

Major intervals are changed to minor, and minor intervals are changed to major. A minor second becomes a major seventh, and a major second becomes a minor seventh. A major third becomes a minor sixth, and a minor third becomes a major sixth; and so on, as in the following examples:—

SECONDS.

SEVENTHS.

THIRDS.

SIXTHS.

## MUSIC.

Intervals are divided into *Consonant* and *Dissonant*.

When two (or more) notes are heard at the same time, it is found that some of these intervals are agreeable and others disagreeable to the ear. The intervals which form the agreeable combinations are called *consonant*, the others *dissonant*. Harmony is not confined to the use of consonant intervals or *concordes* only. On the contrary, the admixture of dissonant intervals, or *discordes*, produces many of its greatest beauties.

The consonant intervals are the *major third*, the *fifth*, and the *octave*, with their *inversions*—namely, the *major* and *minor sixth*, and the *fourth*. The *unison* also may be included; because, though it cannot properly be called an interval, yet it is the inversion of the octave; and when used by two or more voices, is agreeable to the ear, and of use in harmony.

It must, however, be remarked, that though the inversion of the third (the sixth) is as agreeable to the ear as the third itself, yet this is by no means the case with the inversion of the fifth (the fourth); which is so much less agreeable than the fifth, that it requires

(as will be afterwards shown) some of the precautions required in the use of discordes.

The dissonant intervals are the *major* and *minor second*, the *sharp fourth*, the *imperfect fifth*, and the *major* and *minor seventh*.

The *major* and *minor ninth* (the octave of the second) are also dissonant intervals.

### CLASSIFICATION OF CHORDS.

When any note is heard, along with its third (major or minor), its fifth, or its octave, or with all these together, the combination (called a *chord*) thus produced is agreeable to the ear—

Such a chord may be formed upon every note of the scale. The chord so formed is called a *triad*—

The above chords will be found to be of three kinds.

The first kind consists of the fundamental note, with its *major third*, *fifth*, and *octave*, and is formed upon the *key-note*, the *fourth*, and *fifth* of the scale. It is called the *major triad*.

The second kind consists of the *minor third*, *fifth*, and *octave*, and is formed upon the *second*, *third*, and *sixth* notes of the scale. It is called the *minor triad*.

The third kind consists of the *minor third*, the *imperfect fifth*, and *octave*, and is formed on the *seventh* note of the scale. As this chord contains a dissonant interval (the *imperfect fifth*), it is much more sparingly used, and with greater precaution, than the others. It is called the *imperfect triad*.

### TRIADS.

The above triads are formed upon the scale in the key of C major. It would unnecessarily multiply examples to exhibit the formation of the triads in the other keys. This the learner can do for himself; and it may be added (once for all), that the examples and

exercises given in the sequel ought to be written by the learner in a variety of keys, in order to make him familiar with the practice of transposition.

The *minor scale* will give the same triads, but differently placed—

The notes of which a triad consists may be taken in different positions; for example—

In changing the position of a triad, the fundamental note remains in the lowest place, or in the bass. But the triad may also undergo different inversions, by placing the third or the fifth in the lowest place, or bass. The third may be placed in the bass, producing the chord of the third and sixth\*—

The fifth may be placed in the bass, producing the chord of the fourth and sixth.

And every other triad may be similarly inverted.

The triads, therefore, of the tonic and of the dominant are of the most frequent occurrence, and most easily alternate with each other.

Alternations between the tonic and dominant, in different positions—

Alternations between the tonic and dominant, in different inversions—

After the tonic and dominant comes the fourth of the scale, called the subdominant, with its triad—

PROGRESSION OF CHORDS.

Although every note of the scale may thus be made the foundation of a triad (or common chord, as it is also called), yet, in forming a harmonious series of triads, they cannot be made to follow each other at pleasure; but their succession must depend on certain rules deduced from the position of their fundamental note in the scale to which it belongs.

In every scale, the most essential note is the key-note, or tonic. This note, or one of the notes contained in its triad, begins and ends every strain of melody or harmony, and recurs so frequently, that its impression is never lost upon the ear. Melodies frequently consist entirely of the notes of this triad—

Next to the key-note, or tonic, the most essential note is the *fla* of the scale, called, from its importance, the *dominant* or ruling note. By adding this note, and the notes of its triad, to those of the tonic, a larger field of melody and harmony is thrown open.

\* The different positions and inversions of chords used formerly to be marked by what are called *thorough base figures*; but as these are now only to be met with in old music books, their use has been avoided in the present treatise. The modern manner of notation is altogether a better system.

MUSIC.

Alternations of the tonic, dominant, and subdominant triads, in different positions—

Alternations of these three triads, in different inversions—

The triad on the second note of the scale (called the *supertonic*) is the next, in frequency of use, to the preceding three. Its employment may be understood from the following example:—

The above four triads—the tonic, dominant, subdominant, and supertonic—are the most essential. But the triads upon the *third* and the *sixth* notes of the scale (E and A in the scale of C) are also in frequent use, blended with the others; as thus—

The only remaining triad is that on the *seventh* note of the scale, or the *imperfect* triad. One of its intervals (the imperfect fifth) being dissonant, it is much less frequently used than any of the other triads. In order to diminish its harshness, the dissonant note must fall, in the following chord, to the note immediately below it. Thus F, the dissonant note in the triad of B, must fall to E. This is called *resolving the discord*—

Tonic. Dominant. Subdominant. Supertonic.

In the *minor* scale, the principal triads are placed on the same notes, and in the same order, as in the major; that is, on the *tonic, dominant, subdominant, and supertonic*. In the key of A minor, the *relative* to C major, these triads are—

Here, it will be observed, the *tonic* and *subdominant* are *minor* triads. The *dominant* is a *major* triad, and *supertonic* an *imperfect* triad. The following examples will show how they are employed:—

Alternations between the tonic and dominant, in different positions and inversions—

Alternations between the four triads—

In forming progressions of chords, several considerations must be attended to. A chord must be regarded as a harmonious combination of notes sounded at the same time by several voices or instruments; and a series of chords must be regarded as a succession of notes sounded by several performers, and forming several different parts or melodies, heard at the same time.

Care, therefore, should be taken that the notes of each part follow each other smoothly, as in the examples already given. It will be observed, in general, that the bass moves by larger intervals than the upper parts of the chord. The following is an example of the smoothest form in which a progression of triads can be arranged:—

It is not permitted to make any two parts ascend or descend together by *consecutive fifths*, or *consecutive octaves*.

Take, for instance, the progression from the tonic to the supertonic—

Suppose these notes sung by four voices, in the order in which they stand. While the bass sings C, D, the second voice will sing G, A, each note being a fifth (or octave of the fifth, which is the same thing) higher than the notes in the bass; and the highest voice will sing C, D, each note being an octave above the bass. But both of these are prohibited, and may be avoided thus—

Here, while the bass rises from C to D, the second voice falls from G to F, and the highest voice falls from C to A. The progression of the triads is the same, with a different motion of the parts. This motion, when one part rises while the other descends, is called *contrary motion*. When both parts rise or fall, the motion is called *similar*; when one part rises or falls while the other part is stationary (that is, repeats or continues the same note), the motion is said to be *oblique*.

It is not easy to explain why two fifths, heard consecutively in similar motion, should produce a bad effect,

seeing that the fifth is, next to the octave, the most perfect consonance. But the fact is sufficiently ascertained by experience. The prohibition of two octaves in succession is of a different kind. They are not offensive in themselves, and are prohibited only when they would produce a poor and meagre harmony; for a note and its octave being considered as the same, if two parts move in octaves, one of them is, in respect to fulness of harmony, thrown away. There is, consequently, no harm in making two parts move in octaves when the harmony is otherwise as full as is requisite. A whole strain of music may be performed in octaves (as when a man and a woman sing together apparently the same notes); but this is not regarded as harmony at all, in the technical sense of the term.

CHORDS OF THE SEVENTH.

Besides the chords called *triads*, or *common chords*, there is another class of chords, called *chords of the seventh*. From these two classes, every chord used in harmony is derived.

The principal *chord of the seventh* is formed on the dominant, or fifth note of the scale. It is formed by adding a minor seventh to the major triad on that note—

Dominant of C major.

Dominant of A minor.

This chord may be taken in four positions—

Major.

Minor.

## MUSIC.

The dominant seventh is generally followed by the tonic. The dissonant note (the seventh) is resolved, in the major, by falling a semitone, and in the minor by falling a tone into the *third* of the tonic, and the third of the dominant chord rises one semitone into the tonic—

Alternations between the dominant seventh, in its four positions, and the tonic—

### MAJOR.

### MINOR.

The dominant seventh admits of three *inversions*, formed by placing the different notes of the chord in the bass. They are as follow, alternating with the tonic:—

### MAJOR.

### MINOR.

The first inversion of the chord of the seventh is called the chord of the *sixth* and *fifth*; the second inversion is called the chord of the sixth, fourth, and third (or, for shortness, *six-four-three*); the third inversion is called the chord of the sixth, fourth, and second (or, *six-four-two*). These names will be evident from looking at the chords.

In passing from the chord of the dominant to the chord of the tonic, the third in the dominant chord, which is the major seventh, or *leading-note*, of the scale, must ascend by a semitone into the key-note. Thus in the key of C, the note B, in the chord of the dominant, must always be followed in the same part by C, the key-note, in whatever manner the chords may be inverted. Further, the third in the dominant chord ought not to be *doubled*, or sounded in more than one part; because, as this note must be followed by the key-note, if this were done in more parts than one, we should have consecutive octaves, which ought to be avoided. In the preceding examples, the learner will

perceive that the B of the dominant chord is always followed by C, and that it is never *doubled*. In like manner, the *seventh* in the dominant chord, as it must be followed by the third in the chord of the tonic, must not be doubled; because, if it were, consecutive octaves would likewise be produced.

Another chord of the seventh, next in importance to the dominant, is formed upon the second note of the scale, or supertonic.

This chord may be taken in four *positions*, and admits of three inversions, analogous to those of the dominant. The learner will write it in these different forms.

In the chord of the seventh on the *dominant*, the seventh, which is the discord, must be *resolved*, as already

mentioned. In the chord of the seventh on the *super-tonic* (and in every other chord of the seventh), the seventh must be not only resolved, but prepared; that is, this note must be heard, as a consonance in the preceding chord—

Here the C, which is the seventh of the supertonic, is prepared by being heard as the octave in the preceding chord, and resolved by falling to B in the following chord. The F, which is the seventh of the dominant, is also, in this case, both prepared and resolved. But the seventh of the dominant is not necessarily prepared, as may be seen by the examples already given, where it is resolved, though not prepared.

In the following example the seventh of the supertonic is prepared, while the seventh of the dominant is not prepared:—

The following examples are in the key of A minor—

These two chords (the dominant and supertonic) are the principal chords of the seventh; but chords of the seventh (like triads) can be formed on every note of the scale. They are of four kinds—namely,

The *chord of the dominant seventh*, on the fifth note of the key; consisting of a major third, a fifth, and a minor seventh.

The *minor chord of the seventh*, on the supertonic, the third and the sixth notes of the key; consisting of a minor third, a fifth, and a minor seventh.

The *chord of the major seventh*, on the tonic and sub-dominant; consisting of a major third, a fifth, and a major seventh.

The *imperfect chord of the seventh*, on the seventh note of the scale; consisting of a minor third, an imperfect fifth, and a minor seventh.

Of these chords of the seventh, the *dominant* (as already mentioned) is the most frequently used. Next in frequency are the minor chords of the seventh—namely, the chords on the supertonic, the third, and the sixth. More rarely used are the chords of the major seventh, on the tonic and the fourth; and, most seldom of all, the imperfect chord of the seventh, on the seventh.

In every chord of the seventh, the dissonant note must be resolved by descending one degree. In every chord of the seventh (excepting the dominant), the dissonant note must also be prepared, by being heard as a consonance in the previous chord.

In order that these conditions may be complied with, the fundamental note of every chord of the seventh must descend by a fifth (or rise by a fourth) to the fundamental note of the following chord.

Thus the chord of the *dominant* must be followed by the chord of the *tonic*; of which progression examples have already been given. It is not necessary, however (as has also been already shown), that the fundamental note of the chord shall stand in the lowest position. By *inversion*, any of its notes may be placed undermost; but whatever be the inversion, the fundamental progression is considered the same.

In regard to the other chords of the seventh, the fundamental progression to the chord must be such, that the note which forms the *seventh* in the second chord shall be a third, fifth, or octave, in the first. In other words, the dissonant note in the second chord must be previously heard as a consonant note in the preceding chord. This is designated *preparing* the dissonance.

The following are preparations of various chords of the seventh:—

## MUSIC.

Every chord of the seventh must be resolved, by its fundamental note falling a fifth, or rising a fourth, as shown in the case of the dominant. The above chords of the seventh are resolved, as well as prepared; thus—

When a chord of the seventh is resolved, the following chord may be either a triad, or another chord of the seventh. In this manner a series of chords may be formed called a *sequence of sevenths*, consisting of one chord of the seventh followed by another, and prolonged at the pleasure of the composer. It is generally terminated by arriving at the chord of the dominant, followed by the triad of the tonic or key-note. Thus—

The above series commences with the triad in the key of C, and ends with the same triad, preceded by the chord of the dominant. The intermediate chords are all chords of the seventh, in which the dissonant note (the seventh) is first prepared by being heard as a consonance in the preceding chord, and is then resolved by falling a single degree. The preceding passage is more elegantly written thus—

It must be observed that, in passages of this kind, the chords are not usually inverted, as their effect depends on the fundamental notes being distinctly heard in the bass.

### CHORDS DERIVED FROM THE DOMINANT.

That most important note, the *dominant*, may not only be made (as has been already shown) to carry a triad, or a chord of the seventh, but also several secondary chords derived from the above.

By adding the *ninth* to the chord of the seventh, on the dominant, we have the chord of the *ninth* and *seventh*.

This chord must be followed by the triad of the tonic; and as it contains two dissonant notes, both of them must be resolved by descending into the notes of the following chord:—

In the relative minor key, this chord of the ninth and seventh will be resolved thus—

This chord of the ninth and seventh is frequently used *without* its lowest or fundamental note. It then assumes the appearance of a chord of the seventh, on the seventh note of the scale. But in this case, it is treated as if the fundamental note were understood, and will be resolved into the chord of the tonic—

The above chord, when minor, is called the chord of the *diminished seventh*, as it has the appearance of a chord of the dominant, in which the interval of the seventh has been diminished by raising the lowest note a semitone.

These two chords may be *inverted* by placing any of their notes in the bass—

CHAMBERS'S INFORMATION FOR THE PEOPLE.

MINOR.

In addition to the chords which have been already explained, others are formed by raising or lowering, by a semitone, one of the notes of the chord. These alterations are mere licenses, justified, in particular cases, by elegance of effect, without altering the nature or treatment of the chord.

The triad, or common chord, for example, may be altered by sharpening the fifth, so that it may ascend by a semitone, instead of a whole tone, to the subsequent note. Instead of—

The most important of these altered chords is that which is called *the extreme sharp sixth*. It is derived from the chord of the dominant. Suppose we have the following phrase, in the key of C:—

The close or stop on the last chord, which is the dominant triad, may be made more decided by changing the preceding chord, which is the minor chord of the seventh on the second note of the scale of G, into the chord of the dominant seventh on the fifth note of the scale of G, and resolving it into the triad of G, considered as a new tonic—

Take this chord in its *second inversion*, and then *flatten* the lowest note, so that it may fall by a *semitone* to the note following; and we have—

But as this chord, containing a *sharp fourth*, as well as an extreme sharp sixth, is too harsh, the sharp fourth is left out, and it is taken thus—

Or, instead of the sharp fourth, the perfect fifth is inserted—

There are here *consecutive fifths*; as, while in the bass A flat descends to G, in the second part E flat descends to D. In this case the consecutive fifths have no bad effect, and are admitted by the best composers; though others, more scrupulous, avoid them thus—

SUSPENSIONS, &c.

The chords already described are all the *real* or *essential* chords used in harmony. But great varieties of harmony may be produced by blending the notes of one chord with those of another. If, after passing from one chord to another, one or more notes of the first chord are prolonged, so as to be heard at the same time with the notes of the second chord, this is called a *suspension*.

Take, for instance, the common progression from the dominant to the tonic—

The notes peculiar to the dominant may be prolonged into the tonic, thus—

The notes, thus prolonged or suspended, become *dissonances* when they are heard in the second chord; but they are rendered agreeable by being *prepared* and *resolved*. This is perfectly plain, from inspecting the preceding example.

Suspensions may be formed upon any of the progressions from one chord to another which have been already explained. To give examples of these in all their variety, within our limits, is impossible; but the

MUSIC.

following specimen will give the learner an idea of the manner in which they are used. Let him compare the following progression of chords, without suspensions, with the same progression in which suspensions are introduced :—

Without suspensions—

With suspensions—

Such passages are usually written more elegantly, thus—

The suspension may be placed in any part of the chord, either upper or under, the suspended note being always prepared and resolved. For example, in the tenor, or the bass, see the following :—

Suspensions are sometimes, but rarely, resolved by *ascending*. This generally happens when the seventh, or leading note of the scale, rises to the key-note—

*Passing notes* are notes introduced to give a melodious smoothness to the passage from one chord to another, and which, though not belonging to the chord, are yet harmonious to the ear. For example—

## CHAMBERS'S INFORMATION FOR THE PEOPLE.

Here the notes marked with a cross do not belong to the chords, but serve as connecting links to those which do belong to them.

The passing notes are generally unaccented notes, though sometimes they are accented; as—

The following is an example of passing notes placed in the bass :—

*Anticipation* is another mode of introducing notes not belonging to the chords. It is done by anticipating a note—by sounding it before the chord to which it belongs is struck, as in the following passage :—

Lastly, harmony by notes not belonging to the chords may be produced by *pedal notes*. A pedal note (so called from its being generally played on the organ by the *pedals*) is a note in the bass, held on for several bars, while a series of different chords is heard along with it. It is chiefly used in the tonic or the dominant—

### MODULATION.

Modulation is the art of passing from one key to another. A short tune, or melody, generally remains in one key; but in more extended works, it is necessary, for the sake of variety, to diverge into different keys, according to the character and style of the composition. The field of modulation is of almost boundless extent and inexhaustible fertility in musical resources; but their use requires much skill and judgment, and is regulated by certain laws and principles indispensable for the preservation of unity and consistency.

The following simple phrases, all commencing in the key of C, show how a melody may pass into other keys:—

MUSIC.

From C to F. From C to A minor.

This block contains two musical examples on a single staff. The first example, labeled 'From C to F.', shows a melody starting on C4 and moving stepwise to F4. The second example, labeled 'From C to A minor.', shows a melody starting on C4 and moving stepwise to A4.

From C to D minor. From C to E minor.

This block contains two musical examples on a single staff. The first example, labeled 'From C to D minor.', shows a melody starting on C4 and moving stepwise to D4. The second example, labeled 'From C to E minor.', shows a melody starting on C4 and moving stepwise to E4.

The foregoing examples may show how a melody may pass from one key to another. By harmonising them, we see how the chords of one key pass to those of another. It will be observed that the chord of the new key is always preceded by the chord of its *dominant*—

In C. From C to G.

This block shows a piano-style harmonization. The left hand plays chords in the bass, and the right hand plays a melody. The first part is labeled 'In C.' and the second part is labeled 'From C to G.', showing a transition from C major to G major.

From C to F. From C to A minor.

This block shows piano-style harmonization for two transitions: 'From C to F.' and 'From C to A minor.' The left hand provides harmonic support with chords, and the right hand carries the melody.

From C to D minor. To E minor.

This block shows piano-style harmonization for two transitions: 'From C to D minor.' and 'To E minor.' The left hand provides harmonic support with chords, and the right hand carries the melody.

The above are the keys into which we can pass most easily from the key of C major. If the original key is A minor, the keys into which we can pass most easily are, C major, E minor, G major, D minor, and F major—

From A minor to C major. From A minor to F major.

This block shows piano-style harmonization for two transitions: 'From A minor to C major.' and 'From A minor to F major.' The left hand provides harmonic support with chords, and the right hand carries the melody.

The learner may exercise himself in making transitions from A minor to the other keys above mentioned.

In modulating from the key of C to the key of any other note of the scale, the new key will be major or

minor, according as the third in the scale of the new fundamental note is major or minor. Thus the keys of F and of G (as well as C) are major; while the keys of D, E, and A are minor. We do not mention the key of B, as this key, in modulating from the key of C,

CHAMBERS'S INFORMATION FOR THE PEOPLE.

is very rarely used. This note, besides having a minor third, has an *imperfect fifth*, F natural; and to make it the fundamental note of a key, whether major or minor, its fifths must be made *perfect*, by changing F to F sharp—which is not in the scale.

In the above examples of transitions from C major, or A minor, to other keys, these notes must be understood as standing for any major or minor key, from which transitions may be made in the same manner. Thus taking G as the original major key, transitions

may be made to D and C major, and to A, B, and E minor; and taking E as the original minor key, transitions may be made to G major, B minor, D major, A minor, and C major. The learner should exercise himself in writing similar modulations in all the different keys.

The smoothest and most gradual modulation is effected by means of a chord which is common to both keys; that is, which belongs both to the original key and to the new key—

In the first of these examples, the first triad of G belongs both to the original key of C and to the new key of G. In the second example, the triad of F (of which A is the bass) belongs both to the original key of C and to the new key of F.

Modulation is less gradual (though it may be perfectly admissible), although the chord which immediately precedes the new key is not common to both keys—

In the first example, the triad of F belongs to the original key of C, but not to the new key of G. In the second example, the triad of G belongs to the original key of C, but not to the new key of F. This kind of modulation generally produces a *chromatic* melody, or a melody containing an *accidental* semitone in one of the parts; as from F to F sharp, or from B to B flat, as above.

When a chord is succeeded by another, in such a manner that one of the notes of the first chord appears in the second chord, altered by a sharp or a flat, the note must be followed by its alteration in the same part, so as to make a chromatic melody, as in the preceding examples. When the note of the first chord appears in one part, and the altered note of the second chord appears in another part, this produces a fault, called a *false relation*; as, for example—

To be avoided thus—

The following example is a chain of modulations, in which every key is *relative* to that which precedes it. All the modulations are effected by an intermediate chord, which is the dominant seventh, generally employed in one of its inversions—

MUSIC.

E♭      E♭ to C minor.      C minor to A♭      A♭ to E♭      E♭ to

E♭      E♭ to F.      F to D minor.      D minor to C.

We may modulate into a key which is not relative to that which precedes it (or its antecedent), provided that both keys are relative to the primitive key, or the principal key which predominates in the piece of music. Thus, when the principal key is C, we may modulate from D minor to E minor; because, though these keys are not relative to each other, they are relative to the key of C. Supposing the primitive key to be any note, we may modulate immediately from its second to its third, from its third to its fourth, from its fourth to its fifth, from its fifth to its sixth, and from its second to its fifth, and *vice versâ*; these modulations will be generally effected by means of two intermediate chords, as in these examples—

From C to D minor.      From D minor to E minor.      From E minor

to F.      From F to G.      From G to A minor.      From A minor to G.      From

G to F.      From F to E minor.      From E minor to

D minor.      From D minor to C.

Observe that the D in the bass, marked with a cross, does not belong to the harmony of the chord, but must be regarded as a passing note, leading from the bass-note of the preceding to that of the following chord.

In modulating in this way from a key to another which is not relative to it (as from F to G, or from E to F), we must take care that the *primitive* key, to which

both the keys are relative (though not relative to each other), be well determined; for it is only when this precaution is taken that such modulations can be properly employed. We can easily modulate from G major to F major, by means of two intermediate chords, in a piece of music of which the principal key is C major, while we could not do so if the principal key were D or

## CHAMBERS'S INFORMATION FOR THE PEOPLE.

E minor. What is good in the one case might be bad in another; and all the above-mentioned modulations—from the second note of the scale to the third, from the third to the fourth, &c.—can only be used under the above condition.

When the primitive key is minor, in like manner we may modulate from the fourth note of the scale to the fifth, from the fifth to the sixth, from the sixth to the seventh, from the fourth to the seventh, and *vice versâ*. The learner may exercise himself in find-

ing examples of this rule, similar to those given above. In the above modulations into the keys of different notes of the scale, the keys are major or minor according as their thirds, as they stand in the scale, are major or minor, as already shown; as we modulate from C to D minor, E minor, &c. We may also, though more seldom, modulate from C to D major, E major, &c.; but this must be done by a longer chain of intermediate chords, so as to prepare the ear gradually for the transition. For example—

From C major to D major. Or

From C major to E major.

We may pass from a major to a minor key on the same note, and *vice versâ*—

We may likewise modulate from a given key to notes which are not in the scale of that key; as, for example, from C to E flat, B flat, A flat, &c. These modulations ought to be gradually effected, by passing into some intermediate key, which is relative to the keys which precede and follow it. Thus, in order to modulate from C to B flat, we may pass first from C to F, and then from F to B flat—

In order to modulate from C to E flat major, we may pass first from C major to C minor, and then from C minor to E flat; and to modulate from C to A flat major, we may pass from C major to C minor, and thence to A flat—

It may be laid down as a general rule, that as we may pass from a major key to a minor key on the same note (as from C major to C minor), or from a major key to the minor key of its subdominant (as from C major to F minor), we may pass from a major key to all the keys which are relative to these two other keys. Thus from C major we may pass to all the relative keys of C minor, or to all the relative keys of F minor.

Modulations from C major to the relative keys of C minor—

From C to E flat. From C to F minor.

MUSIC.

From C to G minor. From C to A flat.

Musical notation showing two examples of modulation from C major. The first example, 'From C to G minor', shows a sequence of chords: C major, F major, C minor, F major, C minor, G minor. The second example, 'From C to A flat', shows: C major, F major, C minor, F major, C minor, A flat major, C minor, A flat major.

From C to B flat. From C major to C minor.

Musical notation showing two examples of modulation from C major. The first example, 'From C to B flat', shows: C major, F major, C minor, B flat major, C minor, B flat major. The second example, 'From C major to C minor', shows: C major, F major, C minor, F major, C minor, C minor.

Modulations from C major to the relative keys of F minor—

From C to D flat major. From C to E flat major.

Musical notation showing two examples of modulation from C major to relative keys of F minor. The first example, 'From C to D flat major', shows: C major, F major, C minor, D flat major, C minor, D flat major. The second example, 'From C to E flat major', shows: C major, F major, C minor, E flat major, C minor, E flat major.

From C to A flat. Or

Musical notation showing an example of modulation from C major to A flat. The sequence is: C major, F major, C minor, A flat major, C minor, A flat major. The word 'Or' is placed above the second measure.

From C to B flat minor. From C to F minor.

Musical notation showing two examples of modulation from C major. The first example, 'From C to B flat minor', shows: C major, F major, C minor, B flat minor, C minor, B flat minor. The second example, 'From C to F minor', shows: C major, F major, C minor, F minor, C minor, F minor.

The above rules and examples embrace the principal varieties of gradual or regular modulation. But composers, in order to produce uncommon or striking effects, make *abrupt* or *irregular* transitions, by passing from one key to another not related to it (as, from C to B flat, or E flat, or D major, &c.), without the intervention of any intermediate chord. In such cases, the abruptness of the transition is frequently softened by making a pause before striking the chord of the new key; or the same effect is sometimes produced by sustaining a single note, without any harmony, for a little time, and striking a new chord containing this note in its harmony. But the use of the sudden and abrupt transitions cannot be reduced to any rule: it must be gathered from the works of the great masters. They must be cautiously and sparingly used; as departure from rule can be justified only by the effect produced.

There is one kind of sudden modulation which, from its importance, requires especial notice. This is *Enharmonic Transition*.

The diatonic scale (as has been already explained) consists of five tones and two semitones. By dividing all the tones into semitones, we have a scale of semitones, called the *chromatic scale*. In thus dividing the tone, the intermediate sound may be regarded either as the lower extremity of the tone raised, or as its upper extremity depressed; as, the intermediate note between C and D may be either C sharp or D flat. Thus two chromatic scales are formed—a scale by sharps, and a scale by flats. The tone is not divided into two exact

halves, but the difference is so minute, as to be disregarded in practice; C sharp is treated as being the same sound as D flat, and on keyed instruments is produced by striking the same key. But though the intermediate sound between C and D is regarded as the same, whether it is expressed by the name of C sharp or of D flat, yet these names cannot be indiscriminately used in notation. Take, for instance, the chord E, G, B flat, D flat; and then take the chord E, G, B flat, and C sharp. These chords are struck on the same keys of the pianoforte, yet are essentially different in their character and treatment. The chord E, G, B flat, D flat, is a chord of the diminished seventh, which requires to be resolved into the triad of F; the chord E, G, B flat, C sharp, is an *inversion of a different* chord of the diminished seventh (C sharp, E, G, B flat), in which the C sharp is removed from the bottom to the top of the chord; and it must be resolved into the triad of D—

Musical notation illustrating an enharmonic transition. It shows a sequence of chords: F major (E, G, B flat), F major (F, A, C), D major (F sharp, A, C), D major (D, F, A). The transition from F major to D major is achieved by changing the bottom note from E to F sharp.

Here, then, we have the means of effecting an unexpected modulation. If, while in the key of F, we have

## CHAMBERS'S INFORMATION FOR THE PEOPLE.

the above chord with D flat, we may, by changing that note into C sharp (the sound remaining the same), come at once into the key of D.

Enharmonic transitions may be made by means of three chords—the *dominant seventh*, the *extreme sharp sixth*, or the *diminished seventh*.

The chord of the dominant seventh may be changed

into the chord of the extreme sharp sixth; and, *vice versa*, the chord of the extreme sharp sixth may be changed into the chord of the dominant seventh.

If we are in the key of C, for example, by changing the F, the dominant seventh, into E sharp, the extreme sharp sixth, we may come at once into the distant key of F sharp, either minor or major.

And of course we can reverse this progression, by changing the chord of the extreme sharp sixth into the chord of the dominant.

The chord of the diminished seventh is that whereby enharmonic transitions are most frequently made. Any chord of the diminished seventh may be written in

four different ways, its sounds always remaining the same—

In the first of these, the leading note is F sharp, leading to G; in the second, the leading note is D sharp, leading to E; in the third, the leading note is B sharp, leading to C sharp; and in the fourth, the leading note is A, leading to B flat. Thus—

And as each of these triads of G, E, C sharp, and B flat, may be either major or minor, we have here eight different keys into which we may pass from one chord.

The great facility with which many unexpected transitions may be made in this manner, is a temptation which young composers are seldom able to resist. They crowd their music with crude and disagreeable modulations, imagining that they are displaying learning and skill, while they are doing what is in reality very easy. The remarks on this subject by the celebrated Piccini, one of the greatest masters of the Italian school, ought to be kept in remembrance by every student of music—'To modulate,' says this illustrious musician, 'is to take a route which the ear will follow willingly. It even asks to be led; but only on condition that, when arrived at the point to which you have conducted it, it may there find something to repay it for its journey, and may enjoy some repose. If you keep it constantly going on without granting what it demands, it becomes weary, and will follow you no longer. To modulate is not difficult in itself; there is a routine for that as well as all other occupations. The proof of this is found in those *enharmonic modulations* which appear to the ignorant the height of science, and are, after all, the mere sport of learners. To create melody from a given modulation, to quit it only by legitimate means, to return to it without harshness or insipidity, to make the change of modulation a just means of expression, and of judicious variety—these are the real difficulties. But to quit a key almost as soon as we have entered it, to become extravagant without reason or end, to proceed by jumps and skips, merely because we do not know how to remain where we are—to modulate, in short, for the sake of modulating, is to prove that the artist is ignorant of the end of his art, as well as of its principles; and that he affects a superabundance of imagination and learning, in order to conceal the want of both the one and the other.'

The musical instructor can explain the means by which the different kinds of modulation can be effected;

but in the use of these means, the musician must be guided by the dictates of ear, taste, and feeling. It may be said, in general, that the principal key, in which the piece begins and ends, ought to occupy the largest portion of it; and that, in modulating into other keys, those which are most nearly related to the principal key may be dwelt upon at greater length than those which are more distantly related to it. But the varieties in the course of modulation are infinite; and the succession of keys, in any composition, must be the result of judgment matured by experience.

### CLOSES OR CADENCES.

There is an analogy between music and language in regard to *punctuation*. A strain of music is divided into periods, and these are subdivided into clauses; these periods and their subdivisions being marked by closes, or cadences, more or less complete. These closes, or cadences, are found either in melody or in harmony; but the closes of a melody are more strongly marked and defined by the harmony with which they are accompanied.

The principal cadences are those which end on the tonic, or key-note.

The *perfect cadence* takes place when the chord of the tonic is preceded by the chord of the dominant. Its most complete and final form is when the tonic itself is the last note of the melody, and when the fundamental notes of the chords are placed in the bass. The dominant may be either a triad or a chord of the seventh—

# MUSIC.

When the chords are taken in other positions or inversions, the cadence will be less final and conclusive—

Perfect cadences in A minor—

The tonic may be preceded by the subdominant—

This cadence, from the subdominant to the tonic, is not used as a final close, except occasionally in old ecclesiastical music.

In the final cadence, from the dominant to the tonic, the seventh note of the scale (or leading note) must always be heard in one of the parts, and followed by the key-note. In minor keys (as well as major), this

seventh, or leading note, must always be the major third of the dominant chord, and must ascend to the tonic by a semitone.

The next class of cadences are those which end on the dominant, and are called *imperfect*. The dominant may be preceded by various chords—most frequently by the tonic; but also by the subdominant, or the supertonic—

These closes on the dominant are never final; something else is always expected to follow them. A close on the dominant may be rendered more determined by making the preceding chord a dominant, and thus rendering the closing chord a temporary tonic. This is a transient modulation into the key of the dominant of the original key. In the key of C, the chord of D, the supertonic, may be converted into the dominant or dominant-seventh of the key of G—

Or the chord preceding the close may be one of the chords derived from the dominant; the chord of the *diminished seventh*, or the chord of the *extreme sharp sixth*—

A cadence may take place by passing from the tonic to the *subdominant*—

tonic into a temporary dominant, by adding the minor seventh to its chord; thus making a transient modulation into the key of the subdominant—

This may be made more decided by converting the

## CHAMBERS'S INFORMATION FOR THE PEOPLE.

When we expect a perfect cadence from the dominant to the tonic, the ear may be disappointed or deceived, by passing from the dominant to some chord different from the tonic. The most common of these is the *interrupted cadence*, in which the fundamental note of the dominant chord, in place of going to the tonic, rises, by one degree, to the sixth of the scale—

The following are other instances of *deceptive cadences*.—

The use of such cadences is to prevent the strain from coming to a final close, by disappointing the ear of the expected termination, and leading it to expect something more. This is well exemplified in the national air of 'God Save the Queen.' The first part consists of six bars; at the end of the fourth, the melody comes to a close upon the key-note; but, in the bass, this close is *interrupted* by rising from the dominant to the sixth—

The following examples also show how, by such means, variety may be given to the repetition of the same notes in a simple melody:—

### COUNTERPOINT.

Counterpoint is the art of composition in two or more vocal or instrumental parts, in such a manner as to render each separate part smooth and melodious, and at the same time to combine them in the purest harmony. This art is to a great extent deduced from the principles of harmony already explained; but in its practice, various considerations and rules must be attended to, in order to prevent the music from being harsh, and unnecessarily difficult of execution. Many persons can heap together full chords on the organ or pianoforte, who cannot write, with purity and elegance, a simple duet for two voices.

The rules of counterpoint depend in some measure on the number of voices or instruments for which music is written. The fewer the parts, the stricter are the

rules applicable to them. In two parts, things are prohibited which are admitted in three or four. We shall therefore give the principal rules of counterpoint, as applicable to composition in two parts; and shall afterwards show how they may be relaxed when the parts are more numerous.

#### Counterpoint in Two Parts.

Two fifths, or two octaves, are not to be used in succession. This rule, which has been already explained, is of rigorous application in this species of counterpoint.

It is improper to proceed to a *perfect concord* by *similar motion*, except when one of the parts proceeds by a semitone. It is necessary to explain, that the octave and the fifth are called *perfect concords*, and the third and the sixth *imperfect concords*.

## MUSIC.

It is wrong, therefore, in two parts, to use such progressions as these—

But the following are admitted:—

In the melody of each part, considered separately, the intervals ought, as much as possible, to be smooth and easily taken by the voice. This is a rule more of taste than of grammar, and the strictness of its application must depend on the nature of the composition. The ancient masters, who wrote for voices unaccompanied by instruments, did not admit into their melodies the intervals of the sharp fourth, the diminished fifth, nor the seventh. But in modern music, where the voices are supported by instruments, all these intervals are admitted. The principle of the rule, however, ought never to be lost sight of, especially in vocal music.

In considering the two parts together, the same principle should be observed in regard to the intervals of harmony. The intervals most freely used are the *major and minor third*, and *major and minor sixth*. The *unison* and *octave* are seldom used, as their frequent use would render the harmony meagre; there use is there-

fore chiefly confined to the beginning and end of a passage. The *fifth* is used more frequently than the unison and octave, but by no means freely. The *fourth* must be used sparingly, and generally with the precaution of being prepared and resolved; and the same thing is the case with the second, seventh, and other dissonant intervals.

Although thirds and sixths are the intervals most freely used, yet a long succession of either must be avoided as monotonous. Such passages as the following, for example (the first in thirds, and the other in sixths), would be poor and trivial:—

On this account, it is laid down as a rule, that no more than three thirds, or three sixths, ought to be used in immediate succession.

The monotony above exemplified is avoided, and an agreeable harmony produced, by using thirds and sixths so blended together as to prevent the recurrence of too many of the same kind in succession; thus—

It is impossible, in any case, to use more than two similar thirds in succession; and even two major thirds in succession can be tolerated only in one case, which is, when the two upper notes are the sixth and major seventh of the scale, immediately preceding a close; as—

But it would be better to make such a close thus—

Counterpoint, even when it consists merely of concords, may be diversified by the use of the different kinds of motion—the *similar*, *contrary*, and *oblique*. The following, for example, is composed entirely of thirds, sixths, fifths, and octaves:—

The minor seventh, when considered as belonging to the chord of the dominant, may be used without preparation, as also the diminished fifth, or sharp fourth, when considered as belonging to the above chord—

Our limited space prevents us from going further into this branch of our subject, and passing over counterpoint in more than two parts, we arrive at

## IMITATION, CANON, DOUBLE COUNTERPOINT, AND FUGUE.

The preceding pages contain an exposition of the principles of harmony, which are applicable to every species of composition. It remains to point out several resources which are found essential to the production of beauty and variety; as, without a general knowledge of their nature, so as to be able to perceive them when they are used, it is impossible to comprehend and enjoy the works of the great masters. Of these, the principal are *imitation*, *canon*, *double counterpoint*, and *fugue*.

*Imitation* is the repetition, in one part, of a phrase or passage which has already been heard in another part. The imitation may be made either in the unison or octave, or in some other interval above or below. Imitation may be made by *contrary motion*; that is, when descending intervals in the one part are imitated by ascending ones in the other, and *vice versa*; and by *retrograde motion*, when the imitation begins at the end of the imitated passage, and goes backward. Imitations are likewise made by *augmentation*; that is, when the given passage is imitated in notes of double length; and by *diminution*, when this process is reversed. Imitation is *strict*, when the passage is precisely imitated in every interval; and *free*, when the figures of the notes are imitated, so as to produce a general resemblance without an exact imitation of the intervals.

*Canon* is that species of composition in which two or more parts are heard successively, in strict imitation. Canon is based upon imitation; but imitations are introduced and abandoned at the pleasure of the composer; whereas the whole piece or movement called a canon must be in strict imitation. Canon being simply strict imitation, it follows that there are as many kinds of canon as of imitation—in all the different intervals, by contrary and retrograde motion, by augmentation and diminution. Canons may be in any number of parts; but they are generally in two, three, or four. When they are so constructed as to close with a perfect cadence, they are called *finite*, in opposition to those called *endless* or *perpetual*, which go on till the performers think proper to leave off.

*Double counterpoint* is that species of counterpoint which is capable of being *inverted* in such a way that the upper part may be made the under, and the under the upper, without detriment to the goodness and regularity of the harmony. This inversion may take place most easily in the octave; that is, an under part, by being raised an octave, may often be placed uppermost, even though the parts had been written without this intention. But if the inversion is made in any other interval—that is, if the under part is raised a ninth or tenth, an eleventh or a twelfth—many precautions must be taken to render the parts capable of being so inverted. Next to double counterpoint in the octave, that in the tenth, and that in the twelfth, are the most practicable, and frequently used.

*Fugue* is the most complex and difficult branch of composition. A general explanation of its principles, however, will enable the student to understand the construction of the choruses of Handel, and the other great ecclesiastical composers, in whose works the grandest specimens of it are to be found.

Fugue consists of a *theme*, or subject, given out by one part, and imitated by the others according to certain laws, and carried on with that mixture of unity and variety which these laws are calculated to produce. These laws, moreover, though derived from the practice of several centuries, are by no means arbitrary, but founded on sound principles of reason and taste. The fugue is pre-eminently calculated to express the feelings and sentiments of a great multitude; and its noblest examples are to be found in sacred music—in the oratorios of the great German masters, and the anthems of the English cathedral service.

The fugue consists of certain constituent or ele-

mentary parts. First, the *theme*, or subject, which is a leading phrase or melody, constantly heard, in various forms or imitations, throughout the whole piece. Next, the *answer*, which is the imitation of the subject taken up by another part. The correctness of the answer depends on many considerations, which cannot here be entered into. But the great principle on which it depends is the division of the scale into two portions or phrases; the one extending from the tonic to the dominant, and the other from the dominant to the tonic; the one embracing the interval of a *fifth*, and the other the interval of a *fourth*.

## VOICES AND MUSICAL INSTRUMENTS.

In order to reduce to practice the rules of melody and harmony already given, a correct understanding of the distinct qualities and uses of various voices and instruments is indispensable. For want of this, even in a choir containing good voices and respectable instrumentalists, all attempts to produce true harmony have been failures. A voice or an instrument out of its place may destroy the effect of a chorus otherwise well performed. Sometimes a *tenor* voice will attempt to lead the *trebles*; or a *flute* will be employed to play a *counter-tenor* part an octave above its proper place; or even a shrill and powerful female voice may be heard sustaining the notes written for the *contralto*, but in an inverted position, *above* instead of *below* the air, or soprano part. A professional musician may smile at our notice of these gross mistakes; but they are, unfortunately, very common among provincial choirs and amateur societies. It is not uncommon to meet in such associations an individual who can play with some taste and skill upon a certain instrument, while he does not understand its true position in the orchestra; or in other words, its relation to other instruments.

In collecting a vocal choir, the first difficulty is to find good and cultivated *treble voices*. On these the clearness, brilliancy, and effect of vocal harmony chiefly depend. The true treble voice is found only in the vocal organs of women and children. An artificial voice, extending into the treble register, and called *falsetto*, may be produced by a tenor or bass singer; but its effect is generally disagreeable. The treble voices of boys require good cultivation to subdue harshness and produce correct modulation; but before this object is gained, the voice generally changes its character by descending into the *tenor* register. For *trebles*, therefore, we must depend mainly on feminine voices; and one of the chief difficulties in the way of cultivating good vocal harmony in this country is found in the fact, that few young women acquire the art of reading music and singing correctly from notes, while even among these few, domestic cares and occupations often prevent a regular and progressive culture of their musical talents. The difficulty becomes still greater when we inquire for *contralto* voices. The *contralto* part, ranging between the treble and the tenor, and partaking of the qualities of both parts, is often attempted by men's voices, but requires a female voice, like that of Mademoiselle Alboni, to give it with ease and purity. A true voice for this part is rare; and as it cannot be performed by memory so easily as the *air* or *first treble* part, it requires also certainty in reading music. Tenor and bass voices, having moderately extensive registers, are common, as almost every man possesses one of these voices in some degree. When a voice extends from the lowest part of the vocal scale to the tenor C or D, having about a dozen notes, more or less, and preserving its strength and fulness of tone in the lower notes, it is called a *bass voice*, and constitutes the fundamental part in vocal harmony. Fortunately such voices are not scarce, though it is desirable that they should be more generally cultivated, so as to combine sweetness of tone with their sonorous power. One tenor voice differs from another, as it possesses more or less of the bass register. The counter-tenor, or con-

tralto voice, rises some four or five notes higher than the tenor, as this part rises also some four or five notes higher than the bass. Both these tenors are employed in full vocal harmony to fill up the spaces left between the bass and the treble; these parts are therefore sometimes called the *outer* parts, as the tenor and the contralto are termed the *inner* parts of a composition.

The four distinct voices thus briefly described may be combined in various styles. A vocal piece of music may be arranged in two, three, four, five, six, or more parts, and is respectively styled a *duet*, a *trio*, a *quartett*, a *quintett*, a *sestett*, or a chorus for a double choir. Each of these compositions admits several varieties. A duet may be formed of two trebles, or two tenors, or two basses, or of any two of these three parts. It is obvious that the trio must admit various combinations of trebles, tenors, and basses. The most common form of composition in four parts embraces the four distinct voices. In this style of harmony the choruses of oratorios and anthems are generally written. When any one part is doubled—that is, when two trebles, or two tenors, or two basses, are arranged with three other parts—the composition is styled a quintett, or a chorus for five voices: this is a rich style of harmony. We may observe here that the same composition which is arranged for treble, tenor, and bass voices, may be also arranged for male voices only, or, in other words, for tenors and basses; but in this case it will be generally necessary to change the key, so that the first tenor may be high enough to admit under it a second tenor and a bass arranged with distinct and harmonious intervals.

The discordant errors arising from ignorance of the principles just stated are so common, and so entirely destructive of good harmony, that too much can hardly be said to expose them. No singer should consider himself duly qualified, as a member of a choral society, until he has such a clear understanding of the distinct characters and positions of the various voices, and the clefs which determine their registers, as will enable him correctly to fulfil the intentions of a composer.

From the consideration of vocal parts, we now turn our attention to the most important instruments which may be employed to accompany choral performances. These instruments, like the various voices, may be divided into four classes—namely, treble, contralto, tenor, and bass. The chief treble or soprano instruments are the violin, the flute, the clarinet, the hautboy, and the cornet-à-piston. The lower notes of the same instruments are generally employed to fill up the second treble or contralto part; while to sustain the tenor, the instruments chiefly employed are—the *tenor* or *viola*, the *tenoroon*, the *bassoon*, the *tenor trombone*, the *French horn*, and the *tenor ophicleide*. For the bass part, the leading instruments are—the *violoncello*, or bass viol, the *contra-basso*, or double bass, the *ophicleide*, and the *trombone*. Of these and others employed in various parts of music, we may give a brief account:—

The first of all soprano instruments is unquestionably the *violin*, or, to employ the old Saxon name, the *fiddle*. If the organ is esteemed as the king of instruments with regard to its power and fulness of harmony, the violin may justly claim the same title when we consider its pliability and brilliancy, the precision, and indeed the perfection of the melody which may be produced upon it. But as it depends for all its modulations on the mind of the performer, it may be made the worst, as it is in other cases the best of instruments. The invention of the violin in its present form cannot be assigned to any exact date, though it is certain that, in various forms, it has been employed through several centuries. The first suggestion of such an instrument may be found in the vibration of a string tightly stretched over two small blocks of wood or bridges. Other strings, similarly stretched, but in various lengths, will, when agitated, produce various tones; thus seven strings would give the diatonic gamut of the seven notes. But such an instrument would be

but a rude and feeble attempt to produce music: its vibrations, produced by a touch of the finger or the stroke of a quill, would soon die away, and even while they lasted, would have but little power, on account of the want of a sounding-board or hollow shell. To remedy this defect, a shell is made of resonant wood, on which the bridge is placed; and now the vibrations are strengthened and prolonged by being communicated to the shell. Still no long notes can be sustained; the instrument now resembles a lyre or a dulcimer, and has few of the qualities of the violin. But, in the next place, we discover that one string may produce several notes, if it is stretched over a *neck* or finger-board, upon which the finger of a performer may press the string at various intervals, so as to produce various vibrations or tones. We need not now have a string for each note; for one string will produce some dozen notes, while with four strings we can command three octaves and upwards, or more than twenty-four notes. Still we require some means of prolonging vibrations at our pleasure, and this is found in a bow of horse-hair: the fibres of which, when prepared with rosin, are capable of exciting vibrations of a musical string in a *sostenuto*, or prolonged and connected style. The modern violin is now complete, and, though still a simple instrument, seems to ask for no further improvement. Its parts consist of a head, a neck, a shell, a bridge, a tailpiece, and a finger-board. Four strings are fastened on the tailpiece, stretched over the bridge, and after passing over the finger-board, are tightened by movable pegs in the head of the instrument. The tones are then produced by a bow of horse-hair drawn across the strings. It is obvious that such an instrument may be constructed at the cost of a few shillings; but even good materials and fine workmanship are not sure of producing a melodious violin: while some old instruments, especially the Cremona violins of 1660, and others made by Straduarus, have a purity and bell-like clearness of tone which is highly prized by musicians. The violin, therefore, varies in price from ten shillings to £50 or £100. The uses to which this admirable instrument is applied are chiefly two: it is employed in *solo* performances, and in *concerted* music. In the first style, its display of power is curious and interesting; but in the latter it is more important. As a solo instrument, it is capable of producing the most rapid, or brilliant, or smooth melodies, or may be played in harmonious chords. Paganini introduced a style which may be called *trick-play*, which, though curious and amusing, has received too much attention; among many other tricks, Paganini excited surprise by playing a solo on the fourth string. The violin may also be played in the *pizzicato* style, without any use of the bow; and by a peculiar use of the fingers and the bow, tones called harmonics may be produced, distinct from the common tones of the instrument.

But the violin is more important when regarded as the *leading treble* or *soprano* instrument in orchestral or concerted music. Its usual compass extends from the tenor G to D in *altissimo*, including more than 2½ octaves; and several additional high notes may be clearly produced by a skilful performer. But the chief ambition of the violinist who aspires to be useful as a member of an orchestra, should be to play the leading air, or soprano part, with *truth*, *steadiness*, and *flowing clearness of tone*, united with *precision in time*.

The same instrument, when employed to sustain the second treble part, is called the *second violin*. In this part, the lower tones of the instrument are chiefly employed; and as this part is not so prominent as the leading strain, the second violin is sometimes underrated with regard to its importance. It does not often require the brilliant execution of the first violin; but steadiness and correctness of time and tone are demanded in this, as in every part of concerted music.

The *tenor* or *viola* is another stringed instrument made precisely like the violin, but larger in all its parts, and consequently having a *lower register* of notes. Its usual compass extends from the bass C to the

treble C. Several higher notes may be added. It thus appears that the viola bears to the violin the same relation which the tenor voice bears to the treble or soprano. This valuable instrument is too much neglected; for there are no other instruments which can adequately supply its place in sustaining the tenor part. Though in choruses, and sacred music generally, it seldom demands brilliant execution, the due management of its strings requires judgment and taste, as it is apt to produce nasal tones. To avoid these, the upper strings should be played stopped, or in other words, the notes D and A should seldom be given on the open strings.

Another noble instrument of the violin class is the *violoncello*, or *bass-viol*, of which the register extends commonly from double C to D *in alt.* of the bass. Several higher notes may be added. As the violin is the rival of the soprano voice, the violoncello may be regarded as capable of making the nearest approach to the powers of a fine bass voice.

The *contra-basso*, or double-bass-viol, is the largest instrument of the violin class, and is employed to produce a bass part an octave below the violoncello. For this purpose the instrument is provided with the thickest strings employed in music, which are tuned in fourths. The lowest string is tuned to A, the second to D, and the highest to G.

The above-mentioned instruments are the only truly pliable, and, indeed, perfect instruments which have been invented. As the stopping of their strings, in order to produce the various tones, is not regulated by any mechanical contrivance, but depends purely on the mind of the performer, the ideas of tones (which are formed in the mind of a musician with far greater purity and precision than can be expressed by any mechanical process) can be at once interpreted on the pliant strings of the violin and its fellow-instruments. To explain this important advantage more clearly, it must be observed that, though the ordinary musical scale, as represented by the key-board of the organ or pianoforte, contains only tones and semitones, the *mind* can think of *quarter-tones*, and even demands their use, in order to realise pure ideas both in melody and harmony. But these quarter-tones can be produced truly only upon stringed instruments of the violin class. This distinction of tones must not be regarded as too finely-drawn; for it is one which, by the use of a little argument, might be made plain to every one possessing the faculty styled an 'ear for music.'

These observations may suggest the remark, that the multiplication of imperfect instruments has not aided the progress of pure music; and we may venture to add, that if all the array of wooden and brass tubes, and even the key-board instruments, the stately organ and the convenient pianoforte, were swept away, leaving behind only the five *true* stringed instruments already described, then, though we should be deprived of many particular effects and varieties of quality in tone, though we should (happily) lose all the grand effects of *noise*, so often presented to the public as substitutes for music, still no essential part of melody or harmony would be lost. Every chord and passage of harmony might be produced by the four distinct voices and their corresponding stringed instruments. Before we notice other instruments, we must remark that the first care of every Choral or Harmonic Society, next to that of procuring treble, contralto, tenor, and bass voices, should be to find able performers on violins, violas, and violoncellos. Other instruments should be regarded as subsidiary.

The sound of the violin is produced, as we have seen, by the vibration of a string, aided by a shell or sounding-board. The most important among other means of producing musical tones, are the vibrations of air in tubes, excited either by a peculiar action of the lips, as in performance on the flute; or by a reed, as in the mouthpiece of the clarinet; or by the trumpet mouth-piece, used for all brass instruments. All the wind instruments, consisting of tubes formed of wood or metal, may be divided (like the violin and its asso-

ciates) into four classes, according to their relations to the four voices. We may, in the first place, briefly notice the wind instruments made of wood:—

Among the *treble* instruments of this class, the *clarinet* may perhaps claim the first notice; for though its crude tone, when not subdued by the performer's taste and skill, is very unpleasant, yet when duly governed, the same vibrating reed may produce tones which blend well with the human voice. The clarinet is composed of a straight wooden tube, with holes or ventages, to be stopped by the fingers, and also thirteen keys. Its register is extensive, reaching from the low tenor E to C *in altissimo*; thus comprising nearly four octaves, with all their semitones. When well managed, it gives a firm and strong support to treble voices, and may even take the place of the violin; but when in the hands of a vulgar performer, it produces the well-known effects so often heard with pain by musical ears in the village churches of England.

The *hautboy*, or *oboe*, is another reed instrument of the treble class, the sounds of which are produced by a reed differing in form from the reed used in the clarinet. Its register extends from the middle C to C *in alt.* Handel had such an appreciation of the hautboy, that he not only employed it generally to aid the treble voices in his choruses, but also wrote concertos to exhibit its powers.

The *flute* is a wind-instrument without a reed, and its tones are produced, like those of the *pan-pipes*, by the lips of the performer injecting air, with various degrees of force, through the *embouchure*. The vibrations are regulated by six ventages, stopped by the fingers, and eight keys. The flute gamut contains more than 2½ octaves, extending from the middle C to A *in altissimo*, and its chief merit as an orchestral instrument consists in the fluency and brilliancy of its higher notes. The lower notes of its register, from middle C to G *in alt.*, have a pleasing quality of tone, blend well with female or soprano voices, and are employed with good effect in solo execution and duets with the pianoforte; but in the orchestra these lower flute-notes are of little use, as their power is much inferior to that of the violin or clarinet. It should be observed that two flutes taking the part *in alt.* are sufficient to accompany a very powerful orchestra.

The *octave-flute*, the *flûte*, and the *piccolo*, are instruments like the concert-flute, but of a smaller calibre, and are used chiefly in dance-music and military bands. The *flageolet*, which produces shrill sounds like a whistle, is also used in light secular music. All these small instruments of the flute order may be regarded as rather decorative than essential in the orchestra, though in waltzes, quadrilles, and some parts of symphonies, they produce good and lively contrasts with the tones of lower instruments.

The same wind-instruments formed of wood, when taking a second-treble or contralto part, are termed respectively *second-flute*, *second-clarinet*, or *second-hautboy*. It may perhaps be regarded as a defect in the modern orchestra that (excepting the *bassoon*) we have hardly one *tenor* instrument in wood to accompany the tones of the clarinet. The *tenoroon*, a wood instrument played with a reed, is seldom employed. The *bassoon*, a larger reed-instrument, has a very extensive register, descending to double B flat in the bass clef, and rising into the contralto scale. It may therefore be employed to accompany and assist either tenor or bass voices, with which its tones blend remarkably well. As it possesses correctness of intonation and versatility in execution, it may justly be esteemed as one of the most useful instruments in the orchestra.

The most powerful wind-instruments, including the bugle, the cornopean or cornet-à-piston, the trumpet, the Sax-horn, the French-horn, the trombone, the bass-horn, and the ophicleide, are made of brass, and are chiefly used in military bands. In the orchestra these instruments must be employed with refined taste and discretion, as, when coarsely played, they overpower

the sounds of the more delicate instruments to which they should give assistance in *forte* passages. The *bugle*, like all the instruments of this class, produces its sounds by means of a trumpet mouthpiece, through which a current of air is thrown into a metal tube, increasing in diameter until it opens at the end in the shape of a bell. The bugle has a treble scale, and produces, especially in the open air, clear, shrill, and lively tones. But lately, it has been in a great measure superseded by the use of another brass instrument, in some respects superior—the *cornopean*, or *cornet-à-piston*, which combines the qualities of the bugle and the trumpet. Its tones are regulated by the use of three valves; and its scale, including the semitones, extends from the tenor F sharp to C in *alt.*, including about two and a-half octaves. Music for the cornopean is generally written in the key of C, or F, or G; and transposition into the other keys is easily effected by the use of several *crooks*, or additional joints, which alter the depth of tone. Thus music written in C, when played with the F *crook*, is in the key of F. When employing its lower tones, the cornopean may take a *contralto* part, and is then styled the *second cornet* or *cornopean*.

The tones of the *trumpet* are well known, as they are very powerful. Its powers of melody are now extended by the use of *crooks*, keys, and valves; but originally it was an instrument of the most simple kind, consisting of a tube of metal (or even a cow's horn) furnished with a mouthpiece for the compression of the blast of air. In the modern orchestra, the improved trumpet is very effectively used to accompany songs of a bold or martial character, and in the loud and triumphal parts of grand symphonies.

To sustain that important middle part, the *tenor*, no brass or wind instrument is so effective and pleasing as the *French-horn*, or *corno*. It is the most mellow of all brass tubes, and is especially useful in the quality of its long-drawn and well-sustained tones. In compass it descends an octave below that of the trumpet. As its modulations are chiefly produced and governed by the lip, guided by the ear of the performer, no amateur can hope to excel on this instrument unless he possesses a very correct appreciation of musical intervals; or, in common language, 'a good ear for music.' In its construction the corno consists of a long tube of brass, coiled in a circular form, and gradually increasing in diameter from the mouthpiece to the end of the tube, which opens widely like a bell. The key or pitch of the horn may be changed by the use of five *crooks*, or additional pieces of brass tube, fitting in the smaller end of the instrument. Its tones are also modulated in flats and sharps by the insertion of the performer's hand into the bell or opening of the tube. Music for French-horns is generally written in the natural scale of C, without signatures of flats and sharps; and its tones are adjusted, by the use of *crooks*, to the keys in which other instrumental parts are written. The corno does not excel in rapid execution, though it has been sometimes successfully used as a solo instrument. We may here mention some improved brass instruments called *Sax-horns*, made in various sizes, and possessing various registers of notes; these have been used in harmony very effectively, especially by the 'Distin Family.'

The *trombons*, or the *sackbut* of ancient times, is a very powerful instrument, and may be described as a trumpet, the tones of which are regulated by a tube of brass sliding within another, so as to shorten or lengthen the column of air. An instrument made on this principle was discovered among the remains of Pompeii. It is now made in three sizes, and is termed respectively an *alto*, a *tenor*, or a *bass trombone*. The last-mentioned, having the longest tube and the most extensive slide, has a register of notes extending from double C to the tenor G, including all the semitones. The scale of the tenor trombone extends from double F sharp to the treble C, while that of the alto trombone reaches from the tenor F to the treble F. The trombone, possessing the quality of the trumpet, but in a lower register, is

one of the most effective instruments in a military band; but in the orchestra, or when employed in sacred music, it must be used with discretion and reserve.

The *ophicleide* is another very powerful bass instrument, but possesses a fine mellowness of tone, and may be played with a pleasing softness of expression, so as to blend well with both wind and string instruments. The variety of its tones is produced by the use of keys; its register is extensive; and when made in a smaller size than that used for the bass, it produces firm and mellow tones in the tenor scale. The old instrument called a *serpent* has been in a great measure superseded by the ophicleide; but still there is something in the tone of the serpent which is suitable to sustain a firm bass, or double bass part in slow and solemn music.

The instruments which have thus been briefly described constitute the principal parts of a modern orchestra, and by blending or employing in contrast and harmony their various tones in various proportions, the composer produces the effects which are analogous to the powers of colour in painting. But all the instruments named are by no means necessary in forming a little band to accompany the performances of a choral society of moderate power. Two violins, or a clarinet judiciously played, may guide and assist the treble voices; second violins, or (if these cannot be obtained) a second clarinet, may help the second treble or *contralto* voices, and we may also observe that the upper strings of the viola may be used for the same purpose; but this important instrument is chiefly useful in sustaining a steady tenor part. Violoncellos, and a double bass (or *violono*), will give the best support to bass voices. If wind instruments are added to the band, a flute may give relief and brilliancy by taking the part in *alt.* in choruses and full passages; a bassoon may support either the tenor or the bass, or play a mixture of both these parts suited to the capacity of the instrument; and if more instrumental power is required, the cornet, the corno, and the ophicleide (or, in loud passages, the trombones) may be employed.

The above instruments (excepting the violin class) do not severally produce chords. Each plays only one part. We may now give some brief account of *instruments of harmony*, upon which chords or full scores may be played. Among these the *organ* justly claims the first place. Though it has been styled 'the king of instruments,' it is more properly described as a full orchestra of wind instruments, all supplied with wind from a pair of bellows, and placed under the control of one performer. This vast machine of music has no necessary restriction of scale. Its compass may extend from the lowest to the highest musical note appreciable by the human ear. The deepest tones produced by the pedal-pipes have been compared to 'harmonious thunder,' while the highest notes of the smallest metallic stops have the shrillness of a canary's whistling. The organ at Haarlem contains, it is said, 5000 pipes; that in the new church in Amsterdam has 52 whole stops. The immense powers of the organ in York Minster, and that in the Town-Hall of Birmingham, are generally known. The mechanical means by which such an extensive instrument is brought under the command of the hands and feet of one performer are rather complicated, but consist of the following principal parts:—1. A series of stops; 2. A wind-chest; 3. Bellows; 4. Valves and levers to open or close the pipes; and 5. The key-board. Each *stop* consists of a row of pipes answering to the whole gamut or register of the organ, so that a composition may be performed upon one complete stop. But to produce the sound of many instruments, several stops are employed simultaneously. Of these the most important are the *open diapason*, the *stopt diapason*, the *principal*, and the *fifteenth*. When these stops are drawn, the melody and harmony produced are distributed through three octaves.

Other stops are named respectively the *sequentalter*, the *cornet*, the *trumpet*, the *bassoon*, the *flute*, the *oremona*; indeed the number of stops, like that of instruments in an orchestra, may be increased at pleasure.

When a slide is withdrawn, so as to open any stop to the gust of air from the wind-chest, that stop is said to be *drawn*. It may be closed at any moment by the hand or the foot of the player; indeed, the foot can, with a touch on a pedal, bring into action, or reduce to silence, in a moment several rows of pipes equal in power to a large orchestra. The key-board of a first-class organ is divided into three compartments. Of these the lowest commands a series of stops, having generally a soft quality of tone, and collectively styled the *choir organ*; the middle range of keys commands the most powerful stops in the *great organ*; while the third part of the key-board commands the *swell organ* (a series of stops enclosed, as in a box or cupboard, with sides opening or closing at the will of the performer, so as to increase or diminish gradually the volume of sound). The most capacious pipes in the organ are commanded by the pedals played by the feet. To show the extent of the sounds commanded by the hands and feet of an organist, we may give the following chord:—

To find the number of distinct instruments or pipes which are speaking when this chord is played, we have simply to multiply the number of the notes in the chord by the number of drawn stops. Thus if thirty full stops are drawn, the number of speaking-pipes will be 270, or equal to this number of distinct instruments. The 'distinguishing merit of the organ is its power to form and prolong the fullest and most artificial harmonies.' Yet its grandeur and vast compass of tones must not lead us to neglect its defects. It is not a perfect instrument: it cannot accommodate itself to every style of music; but, like all other imperfect instruments, requires music to be purposely adapted to its construction. As it cannot impart to melody the variety and delicacy of expression found in the human voice and the violin, it depends for interest on the boldness and precision of its modulations in harmony. A good composer for the organ must therefore have an extensive command over the resources of modulation, and especially in the *fugue* style. The concertos and fugues of Handel, some pieces by Mendelssohn, but, above all, the fugues of Sebastian Bach, are the finest specimens of organ music. The last may indeed be regarded as the most elaborate modulations of harmony which musical genius has produced, and the organist who can fairly execute them may justly claim the highest rank in his profession.

The *pianoforte* is another instrument of harmony, having an extensive compass, and serving as a very convenient substitute for a small orchestra. It may be regarded as the most characteristic instrument of modern times, and its peculiarities have modified the style of many musical compositions. Like the *harpsichord*, it produces tones by the vibrations of wires; but in the harpsichord the wires were vibrated by a quill: in the pianoforte the wires are struck by a hammer with a surface of leather or felt; and as the force of the blow can be moderated by the touch of the finger on the key-board, the performer has a command over various degrees of force or delicacy of expression. In this respect the pianoforte (a German invention in 1766) is far superior to the old-fashioned harpsichord, which is now very seldom seen. The same lever which impels the hammer against the string, raises at the same moment a damper from the upper surface of the wire, so as to allow free vibration; and immediately when the finger is lifted from a key, the damper falls upon the string commanded by that key, and stops its vibration, so that its sound does not mingle with that of the next note struck, which would often produce confusion instead of harmony. It is important to observe that, in a great number of instruments (especially those of the upright kind, called cottage pianofortes), the action

of the dampers is defective, and consequently the music produced is confused. The great imperfection of all pianofortes is their incapability of sustaining unbroken sounds beyond a few seconds.

In slow and sacred music the pianoforte fails; and as it requires a constant percussion of its wires to sustain its full tones, its powers are most advantageously displayed in rapid and brilliant compositions, such as waltzes, quadrilles, variations of melodies, and sonatas. Beethoven and Mendelssohn produced some of the most beautiful and classical music for this instrument. Other players and composers have displayed its powers in a style which has been termed 'wonder-playing,' and which may be compared with 'trick-playing' on the violin. Playing elaborate and rapid passages in octaves, and distributing chords, in the *arpeggio* style, over the full extent of the key-board (which contains  $6\frac{1}{2}$  octaves), are two of the most brilliant manoeuvres of the modern school. In concert with the flute, the violin, and the violoncello, the pianoforte is exceedingly effective and pleasing, as its chords and brilliant arpeggios make a good contrast with the sustained tones of the other instruments.

The *harmonium*, another instrument with a key-board, capable of producing full harmonies, yields its tones by the pressure of wind upon tongues made of metal in various sizes. It is the nearest approach to solving the problem how to produce organ-tones from a small and portable instrument; but the quality of its tones cannot be compared, for mellowness and variety, with the blended tones of organ-pipes. The *concertina* and the *accordion* are small instruments producing tones by the vibrations of metallic tongues, like those employed in the harmonium.

The *harp* is an ancient stringed instrument, and in its modern form is sometimes effectively displayed in solo performance, though its capabilities are greatly inferior to those of the pianoforte. Its strings are kept in vibration by the fingers of the performer, without the use of a key-board, and each string produces only one distinct note. The *guitar*—which, in its simplest form, is also an ancient instrument—has a neck with several stops or *frets* which produce several notes from one string. It has now six strings, and commands a range of three octaves; but though it is a pleasing accompaniment to a solo treble voice, it is a very feeble instrument, as its tones are transient, and it can be played well only in a few keys. The ancient *lyre* and the *lute* were in some respects like the guitar. The *psaltery* and the *dulcimer* were comparatively rude instruments, producing tones from wires, like those in a pianoforte, but having no dampers, and consequently blending tones in a confused style, very offensive to a cultivated musical ear.

*Bells, cymbals, triangles*, and even rattling bones, are used to mark the time, and add to the effect of some light varieties of music. The *gong* and the *drum* are employed for the same purposes, chiefly in military music. The *tom-tom*, a large, rudely-constructed drum, is still a favourite instrument of music (or rather of noise) among savage tribes. Church bells are still favourite instruments among many rustic amateurs possessing primitive musical taste; but they may be commended rather for the strong physical exercise which they afford to the ringers, than for any truly musical pleasures which they give to hearers.

In conclusion, we may again observe that only a few of the instruments noticed in this article are really necessary for the production of good instrumental, or the accompaniment of choral music. The sensuous effect of music depends partly on fulness and quality of tone; while music, in its more intellectual sense, depends upon the relations of various intervals in sounds arranged in melody and harmony. With four or five well-trained voices, especially when they are supported by the three principal stringed instruments—the violin, the viola, and the violoncello—we are able to produce, not the loudest, but the most beautiful and classical music of the best composers.

## HOUSEHOLD HINTS.

UNDER this head we propose to offer a few advices connected with Housekeeping in general—referring to the choice, furnishing, and management of dwellings; the cleaning of furniture and apparel; the destruction of vermin; precautions as to fire and water; the preparation of small domestic manufactures; and lastly, to the duties of the dressing-room and toilet.

### CHOICE AND FURNISHING.

*Choice of a House.*—There are certain important points on which you should obtain satisfactory information in making choice of a house. *First*, take care that it is not damp. Dampness may arise from several causes, but imperfect drainage, and a too close contact of the floors with the ground, are the principal. When a house is damp in any part, no matter from what cause, it is advisable by all means to avoid it, for it may produce the most pernicious effects on the health of your family. *Second*, see that the house has a free open exposure for fresh air, and, if all other circumstances suit, prefer that which has an exposure to the south, and possesses the beneficial influence of the sun's rays. A house with a pleasant southern exposure enjoys a climate several degrees warmer than a house which is not so favourably situated. In general, too little attention is paid to this circumstance, though it has been proved in the clearest manner that mere sunlight, without reference to heat or air, exercises a most powerful influence on the health and energy of the human frame. *Third*, ascertain if there be a plentiful supply of good water in the premises, and if there be proper means at hand for drying and bleaching clothes. *Fourth*, learn whether the vents go well, and do not smoke. The inquiries you may make in reference to freedom from vermin, exposure to public nuisances, respectability of neighbourhood, and other particulars, are left to your own judgment.

*Furnishing.*—When you design to furnish a house, take care to set out on a right principle in the selection of articles. It is essential, for the sake of neatness, and for a pleasing effect to the eye, that there should be a harmony of colours, and also a similarity of style in the main articles of furniture. Therefore, if you do not exercise a little taste and judgment in your *first* selections, you may find that you have committed a blunder which will cost you much subsequent annoyance. For example, let the tints of the carpet, of the paper or paint of the walls, and of the window-curtains, be all in harmony in each room—that is, either possess a general resemblance of colour, or various colours in pleasing contrast and harmony with each other. If the colour of your curtains be scarlet, and the colour of your walls or carpet blue, a most inharmonious and unpleasing effect will be produced; but brown and green, or green and gold, will be in harmony, and may therefore be placed together. Carpets being the most expensive articles, it is safest to buy them first, and then to let their colour lead the tone and style of curtains, paper-hangings, chair-covers, hearth-rugs, and all other articles. It is also a good economical plan to buy carpets of the same pattern for several rooms, because, in the event of removal to a house with different-sized apartments, a piece of one carpet may be taken to eke out another. It is also of prime importance to have the patterns in keeping with the size and style of the apartments; for nothing looks so patchwork and out of place as large and showy patterns in small old-fashioned rooms—nothing so mean as paltry fabrics in large modern apartments. This remark is alike applicable to every article of furnishing, and demands, on the part of the housekeeper, the strictest attention. Brilliant gaseiers, mirrors, panellings, paper-hangings, and the

like, are admissible only into suitable apartments; and the vulgar-rich will often be disappointed to find that a few well-chosen and properly-arranged articles produce a much more elegant effect than all their lavish, because tasteless and inharmonious display.

Respecting the material of carpeting, matting, floorcloths, and the like, the best your means can afford will ultimately be found to be the cheapest. There is always a great deal of showy but trashy material in the market, which, from its cheapness, is apt to allure the inexperienced; a few months' wear, however, destroys not only its appearance, but renders it next to useless. Cotton mattings, carpetings, and the like, can never compete with a genuine woollen fabric; and the closer and heavier a woollen fabric, the more likely is it to give satisfaction. In purchasing oil-cloth, see that the colours are of a durable kind, and that they are laid on stout, close canvas. Genuine coir and manilla are strong, durable materials for matting, well adapted for stone lobbies and passages. Dressed skins—plain or dyed—make a very elegant and comfortable mat, but they require to be kept dry; and if not thoroughly prepared, the grease which exudes from them will irremediably destroy the carpet on which they are laid.

*Tables, Chairs, &c.*—When you are bargaining for tables, chairs, and other wooden articles of a fine quality, take care to specify that they must be of a solid fabric, and not veneered. Veneering is only tolerable in a few articles which are not to be subjected to much tear and wear; nevertheless, a practice has begun of veneering articles in daily use, such as chairs and tables, and consequently they are soon destroyed. This practice, we are sorry to say, is done in cases where the highest price is paid for solid articles, and we mention the circumstance to put you on your guard. Examine closely the back and seat-frames of every mahogany chair, and reject it if it be veneered. In the case of veneered articles, as cabinets, chests of drawers, wardrobes, sideboards, and the like, see that the veneers be laid on a substantial well-seasoned ground; if not, the veneering is sure to warp and blister after a few months' exposure to the ordinary heat of a dwelling-house. In ordering sofas, chairs, and mattresses, you should also take care to bargain for genuine hair stuffing, for in many instances the stuffing is composed of what is technically called *poë*, or a composition of tow, wool, and other kinds of rubbish. Likewise the hair should be well baked and prepared. We have seen a hair sofa, for which the highest price was paid, swarming with a species of louse, shortly after being sent home from the upholsterer's, in consequence of the animal substance about the hair not having been properly dried by baking. In every case you will be safer to pay a fair price to a respectable tradesman, than to purchase from the self-styled 'cheap warehouses;' for though the articles may be of elegant enough designs, and look as brilliant as French polish can make them, yet in a few years they will become warped, disjointed, and rickety.

*Fire Grates.*—In choosing fire-grates or stoves for your rooms, do not buy those which have burnished steel fronts, as they require a considerable degree of care in cleaning, and are very liable to rust during summer when not in use. The best and neatest, as well as the cheapest grates, are those which are made of cast-iron, and of an ornamental pattern. Let the grates which you select be small or of moderate size in the fireplace. Wide, open grates, by admitting cold air into the chimney, are exceedingly liable to smoke. Kinnaird and Register-grates, with fire-brick or cast-iron backs, and with fronts of cast-iron ground smooth,

are now most generally sought after; and when neatly constructed, are fit for all ordinary purposes. The brilliant grate-fronts exhibited in the windows of the ironmongers are fit only for the houses of the wealthy, who have plenty of servants to keep them in order. Avoid the grates with low-placed bars and open fenders, unless your house is specially constructed for them, as they are apt to cause accidents by fire. In purchasing fire-irons, choose those of solid-wrought iron or steel; have nothing to do with any combination of brass and steel, as they are sure to become loose and rickety after a few months' use.

**Hardware—Cutlery.**—Be particular in your choice of hardware and cutlery, as there is now no branch of British manufactures in which there is greater deception and knavery practised. There are hundreds of workshops in which these articles are made only for 'cheap sales,' and 'sales by auction;' and in such cases only the most worthless materials are made use of. Prefer articles which are cast or hammered to those that are struck up; and see that your cutlery has a full, sound ring, and is sufficiently elastic to resist all ordinary pressure. Avoid the purchase of fantastic shapes and patterns, not only from the difficulty of matching any article in the event of loss or breakage, but from motives of good taste.

**Plate.**—Whatever silver articles you require, buy them of a genuine kind, or of sterling silver plate, which always keeps its value, however old and worn it may become. Avoid all plated goods, for the plating is not long in wearing off, and then the article is valueless. A tarnished plate, fork, spoon, or salver, has an excessively mean appearance. In fact the only tolerable plating is that of electro-plating on steel, and even that, substantial as it appears, is far from being unobjectionable. If you find it inconvenient to purchase sterling silver plate, your most economical plan, consistent with elegance of appearance, will be to purchase a few articles of German silver or albata, which closely resembles sterling silver in texture and colour; it is not just so white as sterling silver, but the difference is not noticed, unless a close comparison be made. In hardness and durability, it is much superior to sterling silver, and its price is in some cases only about a tenth of what genuine plate would cost. German silver is now manufactured to a large extent in England, and is made into spoons, forks, ladles, teapots, salvers, dish-covers, and all other articles for the table. It is not probable that German silver will ever be purchased to a large extent in order to supersede the sterling article, because it possesses no intrinsic value like bullion, but it forms a great stretch in advance of plated or Britannia metal goods, and is likely to come into extensive use. The articles in Britannia metal were once of a durable fabric, but they are so no longer; their good character is gone, and they should on no account be purchased by an economical housewife. A teapot, for instance, of that metal, for common use, and costing six or eight shillings, will probably not last twelve months, while a teapot of German silver, costing from eighteen to forty shillings, will last for fifty years. The German silver article is thus, in the long-run, by far the cheaper of the two, independent of all considerations as to elegance of appearance.

**Gilding.**—Order all the gilding of your picture-frames and other articles to be done in oil. Oil-gilding is not susceptible of flattening and burnishing like water-gilding, but it is infinitely more durable. You may wash an oil-gilt frame without injuring it, whereas one that is water-gilt cannot be cleaned, and is soon tarnished. We never knew a gilder who would gild in oil unless it was expressly insisted upon.

**Earthenware and China.**—In purchasing sets of earthenware articles for the table, also take care to set out on a right plan. Select that set which, in case of breakage, can at all times, and in all places, be easily matched. If you buy a set of table-ware which is peculiar or rare in its pattern, and afterwards break several pieces, you may be put to a very great degree of

trouble, or even find it impossible, to restore them. Thus a peculiar set of earthenware or china, however beautiful and cheap, may ultimately prove a source of vexation and considerable expense.

**Glass and Crystal.**—Articles of this kind are now fabricated in the most elegant shapes and designs, and at extremely moderate prices. There are two sorts in the market—cut-glass, and glass moulded, so as to resemble cut patterns (see No. 21). The latter is cheap, but by no means so elegant or durable as the former, as it is only sound material which will stand the polisher's wheel. Observe, in purchasing glass, that it be well annealed, as otherwise, on the first exposure to hot water, it will fly in pieces. In this respect cut-glass is always preferable to that cast or moulded.

**Baths and Foot-Warmers.**—Few houses possess the convenience of baths (see No. 30), but every one may command the use of small movable bathing vessels for the feet, or for infants. The best foot and leg baths are those made of wood, or of well-tinned sheet iron; those of earthenware are exceedingly liable to break, and, besides, are very expensive. There are various kinds of close vessels for holding warm water, which are used for producing warmth in bed. One of the best articles of this nature which we have seen is a vessel made of sheet tin. It measures twelve inches in length and six inches in diameter, being round like a bottle, with bulged-out rounded ends. At one end there is a small brass screw cap, placed over an orifice at which the water is admitted. This cap being well screwed down, and a small leathern washer being used to assist in the tightening, not a drop of water will ooze out when the vessel is laid in bed. With this simple apparatus, tied in a flannel bag, the feet or any part of the body will be effectually warmed either during illness or in the cold of winter. Stoneware vessels, shaped so as to lie closely to the feet, limbs, or chest, are now largely fabricated, and, if well stoppered, have the advantage of retaining the heat longer than vessels made of metal.

ORDER AND MANAGEMENT.

**Housekeeping.**—Every good housewife is expected to keep a regular and continuous account of her income and expenditure. This is indeed perhaps the most essential in the routine of domestic duties, and she must possess an ill-regulated mind, or have had an insufficient education, who neglects it. When properly set about, and methodically managed, there is little or no trouble in keeping the household accounts. Some housewives have one method, and some have another. Always presuming that we are addressing young housewives in the middle ranks of society, with whom frugality is an object, we beg to suggest the following simple plan of keeping house accounts:—Procure a small slate-book—that is, a little book composed of three slates, bound in a plain cover. This, which you write upon with a slate pencil, is your *day-book*; it is always at hand for you to scroll down any note of outlay, and will keep several days' or a week's accounts at a time. At any leisure moment, you carry the entries of outlay from the slates to a small ruled paper-book, which is your *ledger*. One page of this is devoted to money received, and the opposite page to money paid out. By doing this regularly, and comparing the entries of sums received with the entries of sums expended, so as to see that they square with each other, you will find that you possess a complete record of family expenses, satisfactory alike to yourself and to your husband, should he make any inquiry into the subject. The keeping of an account of receipts and disbursements, in this or any other convenient manner, is calculated to have the most salutary and agreeable effects. The tendency to over-expenditure, or living beyond the means, is constantly checked, or at least you are not deceived upon the subject, and in all likelihood much future distress in circumstances is avoided.

In referring to housekeeping accounts, we must put you on your guard against the very mischievous prac-

## HOUSEHOLD HINTS.

tice of buying on credit, and running up bills with tradesmen. If you can at all avoid taking credit, do so. By paying for every article with ready money, you will possess two decided advantages—you get everything cheaper as you want it, and you can go anywhere to seek out the best markets. Housewives who run up bills, beyond weekly or monthly convenience, become the slaves of tradesmen, and can possess no proper independence of principle or self-respect.

*Servants.*—The old practice of hiring domestic servants for six months at once is rapidly declining. Both mistresses and servants find, by experience, that a bargain for such a length of time very often produces disagreements. It is best for all parties that the term hired for should be only one month at a time, with one month's notice for separation. By this plan a servant can leave a place which does not please her without any lengthened delay; and in the same way a mistress can give a servant warning to quit at a short notice, should it be found that she is unsuitable. In this manner there is no vexatious obligation to keep together, and a separation can always take place amicably. All servants and mistresses who try this plan find it so agreeable, that they never like to change it. Many servants remain years in a place, though hired on the understanding that it is only from month to month, or, what is the same thing, hired for no fixed period, but just so long as both parties agree; and that, in the event of any dissatisfaction, there shall be a week or a month's warning given on either side. This practice has been long common in London, and the sooner it becomes universal the better.

It is a very old remark, that good mistresses make good servants; and though not strictly correct in all instances, there is, on the whole, much truth in it. A good mistress endeavours to seek out and attach a good servant to herself. She effects this attachment and good-will by simply laying before the servant what is to be her line of duties, or what is expected of her, and then leaving her, undisturbed, to execute these duties in a regular methodic manner. No servant likes to be interfered with in her work, or to be called away from one thing to do another; nevertheless, some mistresses are not happy unless they are going in and out of the kitchen, or bustling up and down the house, ordering the servant out of all patient endurance. Mistresses of this fidgetty turn can hardly expect to keep good servants, should they be so fortunate as to procure them. We advise the young housewife to commence on the wise plan of prescribing to her servants, in simple, plain terms, the duties which she expects they will daily and regularly execute; and if the servants are unfit to take advantage of this friendly and liberal arrangement, and require to be continually urged and 'spoken to,' it is better for both that there should be a separation. Where two or more servants are engaged, it is absolutely necessary that the precise duties of each should be expressly defined, in order to prevent disputes between them, and that the work of the house may be duly performed.

As much misapprehension prevails, and some annoyance has been experienced by parties, on the subject of *giving characters to servants*, it may not be without its use to mention, in accordance with our best legal authorities, that the character to be given of a servant must accord with the strict truth. If a false good character be given, and the servant afterwards rob her master or mistress, the person who gave such false character is liable to an action, and to compensate for the entire loss; and is also liable to punishment, in case of false character, by the statute 32 Geo. III. chap. 86. For the protection of masters and mistresses, it has been legally decided that they are not obliged to give a discharged servant any character, and no action is sustainable for refusing to do so. Where a servant has proved unfaithful, the safest and best course to adopt is, for the master or mistress to decline answering any inquiries on the subject.

### CLEANING AND POLISHING.

The best way to clean a house is to *keep it clean* by a daily attention to small things, and not allow it to get into such a state of dirtiness and disorder as to require great and periodical cleanings. Some mistresses, and also some servants, seem to have an idea that a house should undergo 'regular cleanings,' or great washing and scrubbing matches, once every three or six months, on which occasions the house is turned almost inside out, and made most uncomfortable. All this is bad economy, and indicates general slovenliness of habits.

*Wooden Floors.* If kept in order by daily sweeping and other small attentions, may be effectually cleaned by washing them with warm water and soap; but if spots of grease are to be removed, the spots must previously be taken out with fullers'-earth. Ink spots may be discharged with spirits of salt. Some mistresses make a practice of ordering the floors of bedrooms to be frequently washed. We wish to guard both mistresses and servants against this practice. It is most dangerous to the health of the person who occupies the bedroom to wash or scour it, unless the weather be very fine or warm, in order to allow the window to be opened for thoroughly drying the room before night. The utmost that should be done, except in favourable circumstances, is to pass a damp mop lightly over the floor.

*Carpets.*—Ordinary Kidderminster carpets can only be cleaned by shaking and beating; if cleaned by means of washing, they become so soft, as to be speedily dirtied again, and their appearance is spoiled. Brussels carpets may be cleaned as follows:—Take them up and shake and beat them, so as to render them perfectly free from dust. Have the floor thoroughly scoured and dry, and nail the carpet firmly down upon it. Take a pailful of clean cold spring water, and put into it about three gills of ox-gall. Take another pail with clean cold water only. Now rub with a soft scrubbing-brush some of the oxgall water on the carpet, which will raise a lather. When a convenient-sized portion is done, wash the lather off with a clean linen cloth dipped in the clean water. Let this water be changed frequently. When all the lather has disappeared, rub the part with a clean dry cloth. After all is done, open the window, to allow the carpet to dry. A carpet treated in this manner will be greatly refreshed in colour, particularly the greens. It is very advisable, in laying down carpets at first, to cover the floor beneath them (especially if an old floor) with large sheets or webs of paper, so as to prevent dust from rising between the boards. A carpet lasts longer by adopting this precaution.

*Oil-Cloths.*—Oil or painted cloths should be laid only on dry floors; if the floor be in the least degree damp, the cloth will soon mildew and rot. Such cloths, laid even in the driest situation, should be wetted as little as possible. When to be cleaned, they should be wiped with a wet cloth, and rubbed gently till dry. The rubber should be frequently shaken, to free it from sand or gritty particles, which irrecoverably injure the lustre or varnish of the cloth.

*Marble Hearths and Chimney-pieces* may be cleaned as follows:—Mix a gill of soap-lee, half a gill of turpentine, and a bullock's gall, and make them into a paste with pipeclay, which lay upon the marble, and let it remain a day or two, then rub it off, and the stains will have disappeared, unless they are of long standing, when the paste must be again applied. Polished marble requires careful treatment, as any acid will destroy the polish. In general, warm water and soap will be found the safest thing for cleaning chimney-pieces of this description.

*Walls of Houses.*—The outer surfaces of walls, formed of brick or sandstone, sometimes imbibe moisture from the atmosphere, and this gives a dampness to the interior. If it be found unsuitable to plaster, rough-cast, or whitewash the outside, the damp may be greatly prevented by painting the walls with a single coat of oil-paint, which, by being light in colour, will give a neat and clean effect. An ashlar or hewn front may

be well preserved by a coating of hot linseed-oil, mixed with a small proportion of colour, so as to preserve the natural hue of the stone. For further information on the subject of wall-plasters, cements, and stuccoes, the reader is referred to Vol. I., p. 333.

**Walls of Rooms.**—When walls of rooms or staircases are to be painted in oil, let the paint be of the best description. It is not unusual for inferior tradesmen to use whiting, instead of white lead, as a pigment; by this deception the paint will afterwards scarcely endure washing. Supposing, however, that the paint has been of the best kind, considerable care will be required in cleaning it. The safest and most simple plan is, to take a pail of hot water, and put into it as much common yellow or soft soap as will raise a lather or froth. Now wash the walls well with a flannel cloth dipped in this water; then wash this soapy water off with clean flannel and clean warm water. Dry with a clean linen cloth. Do all this equally, so as not to leave smears, or parts better washed or wiped than others. If soda or potash be added to the water, it destroys the varnish or gloss of the oil-paint, and gives it the appearance of flat-painting, or painting in distemper.

**Paper-Hanging** should be first dusted, and then cleaned by a stale loaf of bread, with the crumb surface cut smoothly, and gently rubbed, the dirty face of the bread being cut away from time to time. The imitative marble-paper, highly varnished, may be washed with cold water and soap. *Papier-mâché*, now much used for mouldings and ornaments in rooms, may be cleaned with soap and water.

**Picture-Frames** of varnished or French-polished wood may be washed with soap and warm water, and sponge or flannel. As already mentioned, frames which are gilt in the ordinary manner, or 'water-gilt,' cannot endure washing or rubbing; but if 'oil-gilt,' they may be washed with cold water and a soft brush.

**Ivory** may be restored to its original whiteness by cleaning it with a paste of burnt pumicestone and water, and then placing it under glasses in the sun's rays. Some attempt the use of diluted acids, but this requires extreme caution and expertness.

**Brass inlaid Work** is best cleaned as follows:—Mix tripoli and linseed-oil, and dip into it a rubber of hat, with which polish the work. If the wood be ebony or rosewood, polish it with a little finely-powdered elder-ashes; or make a paste of rottenstone, a little starch, sweet-oil, and oxalic acid, mixed with water. The ornaments of a French clock are, however, best cleaned with bread-crumbs, carefully rubbed, so as not to spoil the woodwork. Ormolu candlesticks and lamps may be cleaned with soap and water. They will bear more cleaning than lackered articles, which are spoiled by frequent rubbing, or by acids, or strong alkalis.

**Windows and Looking-Glasses.**—Dip a moistened rag or flannel into indigo, fullers'-earth, ashes, or rottenstone, in impalpable powder, with which smear the glass, and wipe off with a dry soft cloth. Powder-blue or whiting, tied up in muslin, and dusted upon the glass, and cleaned off with chamois leather, also gives glass a fine polish. The spots in the silvering of old looking-glasses are caused by damp at the back. The Vauxhall plates are no longer prized, for the glass made in the present day is whiter and better. Window-panes may be made to resemble ground-glass by daubing them with putty, or a brush with a little thin paste.

**Brass and Copper** are best cleaned with sweet-oil and tripoli, powdered Bath-brick, rottenstone, or red brick-dust, rubbed on with flannel, and polished with leather. A strong solution of oxalic acid in water gives brass a fine colour. Vitriol and spirits of salts soon make brass and copper very bright, but they very soon tarnish, and consequently require more frequent cleaning. A strong lye of roche-alum and water will also improve brass.

**Stove-Grates** are cleaned with black-lead mixed with turpentine, or with stale beer and yellow soap, and polished off. The finer lead is used dry, in lump or powder. The bronzed work of stoves should be only lightly brushed. Rottenstone, or fine emery and sweet-

oil, is used for the bright work of stoves and polished fire-irons; the higher the latter are polished, the less likely are they to rust. To prevent rust in articles not often used, rub them with sweet-oil, and dust over them fine lime; or with the following mixture:—To a quart of cold water add half a pound of quicklime; let it stand until the top is clear, when pour off the liquid, and stir up with it some olive-oil, until it becomes of a pasty consistence, when it should be rubbed on the metal articles to be preserved. To fill cracks in stove-backs, make a paste of wood-ashes, salt, and water. To remove rust, mix tripoli, sulphur, and sweet-oil, and clean the articles with it; or mix boiled soft soap with emery No. 3, which will also discharge the fire-marks from bright bars. Steel-work may also be kept from rust by varnishing it with turpentine in which is dissolved a small proportion of India-rubber (caoutchouc). Polished fire-irons may be best preserved from rust by being closely wrapped up in strong brown paper.

**Kitchen Vessels.**—The crust on boilers and kettles, arising from the hard water boiled in them, may be prevented by keeping in the vessel a marble, or a potato tied in a piece of linen. Tin-plate vessels are cleanly and convenient, but unless dried after washing, will soon rust in holes. Iron coal-scoops are liable to rust from the damp of the coals. The tinning of copper saucepans must be kept perfectly clean and dry, in which case they may be used with safety. Copper pans, if put away damp, or a boiling-copper, if left wet, will become coated with poisonous crust, or verdigris. Untinned copper or brass vessels, even if scoured bright and clean, are always dangerous. If made dishes be allowed to cool and stand for some time in copper vessels, the articles will become poisonous. In the year 1837, a lady and her family, residing in Paris, were poisoned by partaking of a stew which had been allowed to stand and get cold in a copper pan. A German saucepan is best for boiling milk in. This is an iron saucepan, glazed with white earthenware instead of being tinned, the glaze preventing its tendency to burn. A stewpan made like it is also preferable to a copper pan, since simple washing keeps it sweet and clean. A method of glazing saucepans with earthenware is now common in this country. Zinc sieves are more easily kept clean than those made of hair, will last longer, and not rust.

**Dish-covers** are cleaned with fine whiting and sweet oil, and polished with dry whiting powder. Britannia-metal teapots, &c. should be rubbed with sweet-oil on flannel, then polished by the hand with rottenstone, and next washed with soap and hot water, and finished with wash-leather and whiting powder. Pewter is scoured with fine white sand and a lye made with wood-ashes, or soda and water. A useful paste for tins, brasses, and the like, is composed of rottenstone, soft soap, and oil of turpentine. The stone must be powdered, and sifted through a muslin or hair-sieve; mix with it as much soft soap as will bring it to the consistency of putty; to about half a pound of this add two ounces of oil of turpentine. It may be made up in balls or put in gallipots; it will soon become hard, and keep any length of time. The articles to be polished should be first freed from grease and dirt; after which, moisten a little of the paste with water, smear it over the metal, then rub briskly with dry rag or wash-leather, and it will soon bear a beautiful polish.

**Knives** are best cleaned by rubbing on a flat board, on which is put finely-powdered brick-dust. Some recommend leather to be put on the board; this may prevent the knives from wearing, but it is apt to deprive them of an edge fit for cutting. Never put knives in hot water, for that loosens the handles, and spoils the temper of the steel. For simple cleaning after use, wipe them only with a damp, and then with a dry cloth. Machines for cleaning knives by the dozen are common in hotels; but as they all act upon the principle of rapid friction, they are by no means suited to the economical wants of a household.

## HOUSEHOLD HINTS.

**Lamps.**—When lamps are foul inside, they should be cleaned with hot water and pearl-ash, and well rinsed, and set by the fire to dry before the oil is again put in. Spirit-lamps should be filled with great care, lest the spirits take fire; and unless the spirits of wine be pure, it will not burn. Naphtha, which is burnt in some lamps, is so inflammable as to be dangerous.

**Lamp-Glasses.**—If the lamp-glasses be ground, burnt spots upon them cannot be removed; but they may be cleaned from the effects of smoke by washing with soap and water, and then rubbed with a dry cloth. The glasses should always be ground on the outside.

**Furniture.**—Mahogany furniture is always best cleaned by continual rubbing; and no ordinary stuff that may be applied will compensate the want of this requisite. Some furniture is what is called 'French polished;' but this French polish is an unguent possessed and applied only by cabinet-makers, and cannot readily be had by housekeepers. In ordinary circumstances, therefore, the furniture must be well rubbed, and with some easily-procurable material. The following are the materials we suggest:—Take a gill and a-half of unboiled linseed-oil, one gill of turpentine, and a teaspoonful of pounded loaf-sugar. Shake all well together, and rub a portion on the furniture with a piece of flannel, and polish with a linen cloth.

An oil for darkening furniture may be made as follows:—Mix in one pint of linseed-oil an ounce of powdered rose-pink, to which add one ounce of alkanet root, beaten in a metal mortar; let the mixture stand in a warm place for a few days, when the substances will have settled, and the oil, of a deep rich colour, may be poured off for use; or mix one ounce of alkanet root, four ounces of shell-lac varnish, two ounces of turpentine, and the same quantity of scraped bees'-wax, with a pint of linseed-oil; and when they have stood a week, the mixture will be ready for use.

Furniture-paste is made by scraping a quarter of a pound of bees'-wax into half a pint of turpentine, and letting it stand to dissolve. This will keep the wood light. If, however, a quarter of a pint of linseed-oil be added to the above, the composition will darken the wood. Another paste, useful for very light wood, is made as follows:—In a quart of hot water dissolve six ounces of pearl-ash, add a quarter of a pound of white wax, and simmer the whole for half an hour in a pipkin; take it off the fire, and when it has cooled, the wax will float upon the surface, and should be worked in a mortar, with a little hot water, into a soft paste. With this furniture may be highly polished, as may also marble chimney-pieces. It is necessary to mention that furniture cleaned with paste has the disadvantage of receiving heat-marks more readily than if polished with linseed-oil, which, however, requires more time and labour. In any case, the furniture should be cleansed from grease and stains before polishing is attempted; and this may be done by washing the wood with hot beer, or with soap and water. The safest way to heat furniture-paste or oil is, to place the vessel containing it in another holding boiling water upon the fire, in the manner of a glue-pot.

A fine varnish for mahogany or other furniture may be thus made:—Put into a bottle two ounces of gumsandarac, one ounce of shell-lac, half an ounce of mastic, half an ounce of gum-benjamin, one ounce of Venice turpentine, and a pint of spirits of wine. Colour red with dragon's blood, or yellow with saffron. Let it stand in a warm place until the gums are dissolved, when strain it for use.

**To extract Ink from Mahogany.**—Dilute half a teaspoonful of oil of vitriol with a large spoonful of water, and apply it to the ink spot with a feather: let it lie for a few minutes, and rub it off quickly; and repeat if not quite removed. This receipt of course is only applicable to plain mahogany; the sulphuric acid or oil of vitriol would destroy any varnish, such as French polish, upon which it might be laid.

**Varnishing.**—Before new furniture is varnished, it should have a coat of boiled oil (if wished to be dark-

ened) or linseed-oil, and be left a day or two to harden; or a thin size, made from isinglas or gum-tragacanth, dissolved in water, or very thin glue, is used; so that the pores of the wood be filled up, and both varnish and time be thus saved. A good varnish may be made by dissolving eight ounces of white wax and half an ounce of yellow rosin in a pint of spirits of turpentine.

**Bottles.**—Cut a raw potato into small pieces, and put them in the bottle along with a tablespoonful of salt, and two tablespoonfuls of water. Shake all well together in the bottle till every mark is removed, and rinse with clean water. This will remove stains of wine, green marks of vegetation, and other discolourations. Hard crust in bottles may be cleaned off by rinsing with water and small shot. Take care to wash out all the shot before putting the bottles aside.

**Plate.**—Articles of plate, after being used, should be washed in hot water; or, if stained, they should be boiled, and rinsed and dried before you attempt to clean them. They should be carefully handled, else they may receive deep scratches, which are very difficult to remove. Besides, the object is not merely to clean the plate, but to polish it, so that it may appear almost as brilliant as when it was received new from the silversmith. For this purpose quicksilver was formerly much used in plate-powder, and it gave the silver great lustre, which soon, however, disappeared, and the article became tarnished and blackened. The best plate-powder consists of dried and finely-sifted whiting or chalk. The greater part of the whiting sold in the shops is coarse trash, unfit for rubbing upon plate, and great care must be taken to procure the finest London whiting, which will not scratch.

Brushes, hard and soft, sponge, and wash-leather, are requisite for cleaning plate: if the powder be mixed with spirits of wine laid on with a sponge, and rubbed off with wash-leather, all tarnish will be removed. Salt stains (blackish spots) and sulphur marks from eggs are more difficult to remove. It is a good plan to boil a soft fine old cloth in water with some prepared chalk dissolved in it, and to dry the cloth, and use it for polishing. The soft brush is for the same purpose, the hard brush being for chased work, edges, and crests, so that not a portion of dry powder may remain in them. Plate should in all cases be finished with a fine dry wash-leather. Plated articles should be carefully wiped dry after washing them, else they will rust or canker at the edges, where the silver first wears off; and on this account also they should be cleaned as rarely as possible. German silver may be cleaned in the same manner as plate.

**Embroidery and Gold-Lace** should be cleaned only with spirits of wine, or brushed with finely-powdered roche-alum and chalk. For gold chains, dissolve three ounces of sal-ammoniac in six ounces of water, in which boil the chain; then boil it in soft soap and water, wash it in cold water, rub it dry with flannel, and shake it in a bag with very dry bran.

**Flannel or Woollen Articles.**—Wash them quickly in moderately-warm water with soap. Wring and shake them well, and hang them up to dry. Do not let them lie wet. The more quickly they are dried, the less likely are they to shrink.

**Silks.**—No silks look well after washing, however carefully it be done, and should therefore never be resorted to but from absolute necessity. We have seen it recommended to sponge faded silks with warm water and soap, then to rub them with a dry cloth on a flat board, after which to iron them on the inside with a smoothing iron. Sponging with spirits will also improve old black silks. The ironing may be done on the right side, with thin paper or muslin spread over them, to prevent glazing.

**The Colour of a Print Dress** may be preserved by separating the body and train, and washing in cold rain or river water, into which a handful of salt has been thrown. Instead of spreading the dress to dry, it should be rolled in a coarse cloth, and allowed to remain till dry enough to be ironed.

**Bed Feathers.**—Put a manageable quantity into a pillow case or bag, which wash with warm water and soap. Wring out the lather, and rinse them in clean water. Wring them as dry as possible, and hang them up to dry. Shake them frequently while drying. When quite dry, beat them, to free them from any dust. The feathers may be now taken from the bag, and are ready for use.

**Lace.**—When lace has lost its colour, soap it well, and put it in cold water, just enough to cover it. If much discoloured, change the water at the end of twenty-four hours. When steeped sufficiently, rinse it out; starch it a little; pick it out as evenly as possible; roll it in a towel, and when nearly dry, iron it. All lace veils may be treated in a similar manner.

**Scarlet Cloth.**—Pour boiling water upon bran, strain it, and, while hot, wash the cloth in it, and rinse with hot water. Soap should not be used. Purple cloth may be washed in hot water and pure lye. Saxony or dark-print dresses should be washed in two lathers, and in the second should be poured a little ox-gall, which will freshen reds, blacks, and greens; and a handful of salt added to the last rinsing-water will prevent the colours running.

**Clear Starching** is practised as follows:—Rinse the articles in three waters, dry them, and dip them in a thick starch, previously strained through muslin; squeeze them, shake them gently, and again hang them up to dry; and when dry, dip them twice or thrice in clear water, squeeze them, spread them on a linen cloth, roll them up in it, and let them lie an hour before ironing them. Some persons put sugar into the starch, to prevent it sticking while ironing; and others stir the starch with a candle, to effect the same end; we object to these practices as injurious to the article starched, or as very nauseous. The best plan to prevent sticking is to make the starch well, and to have the irons quite clean and highly polished.

**Stains.**—Stains of fruit or wine may be generally removed from linen or cotton cloth by placing the articles over the top of a pail, and pouring boiling water through them till the marks disappear.

**Ink Marks or Iron Moulds** may be removed by placing a plate (a pewter one is the best) on the top of a basinful of boiling water; then spread the articles on the plate; wet the spot, and rub it with a small quantity of the salts of lemon; as the article dries, the stain will disappear. If this fail, repeat the operation. A small box of salts of lemon will be found very useful in a household. **Mildew** may be removed from linen by the following process:—Rub the cloth well with soap; then scrape some fine chalk, and rub it also on the stained part. Lay the linen on the grass, and, as it dries, wet it a little; the mildew will be removed by one or two applications at most.

**Paint or Grease-Spots** may be removed from woollen cloth by turpentine. Smith's scouring drops is a liquid sold in small bottles, which will also be found efficacious in removing oil or grease marks; it is more expensive than turpentine, but has a less offensive odour.

**To extract Grease from Silk.**—As soon after the discovery of the injury as possible, hold the part firmly, and with a clean soft white cloth, or an old cambric handkerchief, rub the spot briskly, changing the portions of the handkerchief frequently, and in a minute or two the spot will disappear. On silks which fray easily, this plan will be unsuitable.

#### DESTROYING VERMIN.

The best plan for preventing the attacks of vermin in houses is to keep the house scrupulously clean; for where there is cleanliness and ordinary precautions, no vermin will generate or exist.

**Rats and Mice.**—These might in most instances be completely prevented from encroaching in dwellings by giving a solid foundation to the house, cutting off the approach by grating the drains, but especially by filling up all open spaces beneath pavements and in walls and partitions. Mice might be effectually kept

out by only filling up the spaces behind skirting-boards in rooms. These vacant spaces are invariably the habitations of mice; and the first thing any person should do in entering into possession of a domicile, is to cause all the spaces behind the skirting-boards and wainscots to be filled with plaster. Where mice and rats have gained a footing in a house, they should be taken off by a cat or trap, and when one kind of trap fails, another may be tried. All schemes for poisoning them with arsenic or other ingredients are dangerous; and even were they not so, the animals, having partaken, may retire to their holes, and dying there, cause an intolerable stench. The following method, which is said to be effectual, is free from these objections:—Take oil of amber and ox-gall in equal parts, add to them oat-meal or flour sufficient to form a paste, which divide into little balls, and lay them in the middle of the infested apartment. Surround the balls with a number of vessels filled with water—the smell of the oil is sure to attract the rats, they will greedily devour the balls, and becoming intolerably thirsty, will drink till they die on the spot.

**Bugs.**—These pests exist only in dirty houses. A careful housewife or servant will soon completely destroy them. The surest method of destruction is to catch them individually when they attack the person in bed. When their bite is felt, instantly rise and light a candle, and capture them. This may be troublesome, but if there be not a great number, a few nights will finish them. When there is a large number, and they have gained a lodgment in the timbers, take the bed in pieces, and fill in all the apertures and joints with a mixture of lime and soft soap. A piece of wickerwork called a bug-trap, placed at the head of the bed, forms a receptacle for them, and then they may be daily caught till no more are left. Fumigations are very dangerous, and rarely effectual; therefore attempt no such project. Oil-painting a wall is a sure means of excluding and destroying them. The following extirpating mixture is given on high authority:—Spirits of wine, half a pint; spirits of turpentine, half a pint; crude sal-ammoniac, half an ounce; corrosive sublimate, one ounce; camphor, one ounce. This mixture should be inserted into the joints of bedsteads, &c. with a syringe, and with a sponge fastened to a stick: every part of the wood-work must be washed with it. Many bug-poisons, in fact, are to be had at the chemists; but it is not only unpleasant, but dangerous to have such mixtures about a house: and, after all, they are really less effective than unremitting cleanliness. As means are taken to destroy, so means ought to be taken to prevent the introduction of these pests, which are often brought from one house to another in clothes, in old furniture, travelling-bags, books from libraries, servants' chests, and even in the old cut-wood sold for kindling fires.

**Fleas.**—There is no way of ridding a bed or house of these vermin but excessive cleanliness. Keep the floors well swept and washed, and if you have a dog, comb and wash it frequently. Fleas are bred on the ground, or among dust; and it has been said that to destroy one in March or early spring is destroying hundreds.

**Lice** are now almost unknown in England. Wherever they are found, there certainly also is found dirtiness. Ignorant people imagine that these nauseous vermin breed spontaneously: this is a gross error. By cleanliness they are completely prevented; and the warmer the climate, so is the necessity for cleanliness greater.

**Beetles, Cockroaches, and Crickets.**—These may be caught in traps, without the disagreeable and dangerous expedients of poisoning or fumigation. A simple trap for them is a glazed basin or pie-dish half-filled with sweetened beer or milk, and to the edge of which a piece of wood is laid from the floor as a gangway. 'I took a water ewer,' writes a seafaring friend whose cabin was infested with cockroaches, 'and baited it with a little treacle on its bottom—for of all sweets, and this in particular, they are exceedingly fond; and attracted by it during the night, they dropped in to

## HOUSEHOLD HINTS.

satisfy their appetite. Once in, they could not clamber up the steep smooth sides of the vessel, and in this manner I had it filled, night after night, within two inches of the brim.'

**Flies.**—It is difficult to rid a house of flies by any other plan than poisoning, and that is too dangerous to be recommended. A composition of milk, sugar, and pepper will attract and kill them, and so will a decoction of quassia sweetened with sugar; but both cause them to make offensive marks on the walls and furniture before they die. Gilt frames and chandeliers should be shrouded in thin yellow gauze or paper, in situations where the flies are likely to spoil them. Trees near a house form a harbour for flies, as well as dirt and offensive odours of all kinds. Cleanliness and airiness are the best preventives.

**Moths.**—The best way to preserve furs or worsteds from moths is to sew them closely up in a bag of new unwashed linen; if this be not done, the next best is to take the articles frequently out and brush and air them. The odour of camphor, shavings of Russia leather, lavender, &c., are much less efficacious than they are supposed to be. Kill every flying moth which you see.

**Slugs.**—Take a quantity of cabbage leaves, and either put them into a warm oven, or hold them before a fire till they are quite soft; then rub them with unsalted butter, or any kind of fresh dripping, and lay them in the places infested with slugs. In a few hours the leaves will be found covered with snails and slugs, which may then be destroyed in any way you think fit.

### ESCAPES FROM BURNING, &c.

**Precautions as to Fire.**—Houses are said to take fire by accidents; but these accidents are in general only acts of carelessness, and could, with a reasonable degree of prudence, be avoided. As prevention is better than cure, we offer the following advice:—

Never leave a candle burning at your bedside, or on a table when you go to bed, except it be a rush, wax, or floating light, burning in a basin at a considerable distance from the bed or window curtains. The best place for setting the light is on the hearth.

Never put hot cinders or ashes into a bucket to set aside in a closet.

If you light candles with pieces of paper, take care that the burning paper is completely trampled out after being used. It is always safest to light candles and lamps with a small wax taper, which can be at once blown out. In large manufactories, where there are many lamps or gas-burners to light, let the lighting apparatus be a small hand-lamp, which shall be in charge of a particular person in the premises.

Never blow gas lights out; always turn them off; and turn off the gas at the main stopcock at the door. Should the gas from any cause have escaped, and the smell be suddenly and offensively felt, at once turn off the supply at the meter or stopcock, and open the windows to allow the entrance of fresh air. Be careful not to take a lighted candle into the apartment where the escape has taken place.

Cause the chimneys to be swept once in three months, or oftener if necessary, so as to prevent the accumulated soot from catching fire. Sometimes houses are set on fire from beams which encroach upon the chimneys. House builders ought to be particularly cautious in preventing any part of the woodwork from coming in contact with the flues.

The following are advices how to act when the catastrophe of fire actually takes place:—

**Chimney on Fire.**—To extinguish speedily the fire in a chimney, it is only necessary to hang over the fireplace a piece of wet carpet or blanket: some handfuls of salt thrown into the fire at the same time will greatly aid the extinction. It is also recommended to scatter a handful of flowers of sulphur over the duller part of the burning coals, the mephitic vapours arising from which will not support combustion, and consequently extinguish the flames. Throwing water down from the top is a clumsy expedient, by which much damage is

frequently done to furniture; so also is stopping at the top, by which the smoke and suffocating smell of the burning soot is driven into the apartment. If every fireplace were provided with a damper, or shutter of sheet-iron, sufficiently large to choke it thoroughly, fire in chimneys would become of little consequence, as it would only be necessary to apply this damper to extinguish them. All good modern grates are furnished with such dampers. To set chimneys on fire with a view to clean them is highly objectionable, even where there is no danger of fire to be apprehended, as the intense heat produced rends and weakens the walls.

**Clothes catching Fire.**—The moment you see that your clothes are on fire, remain still and collected; do not, on any account, run away in a fright. If there be a loose rug, carpet, or table-cover at hand, snatch it up and roll it tightly about you. If you can get this done smartly, the flames will immediately be extinguished. Should no cloth of any kind be at hand, and no one be present to give assistance, lay yourself down on the floor, and try to extinguish the flames by rolling yourself about, always taking care to keep the garments as close together as possible. If a man be present, let him take off his coat and wrap it round you; and if a woman, her shawl will answer the same purpose. By one or other means, such as are here pointed out, the fire will be stifled, and perhaps the only personal injury will be some slight scorching of the hands, which must not be regarded in averting an infinitely greater evil.

[For remedial applications in the event of injuries from fire—as burns, scalds, &c.—see *HOUSEHOLD SURGERY*, Vol. I. page 764.]

**House on Fire.**—In making way through a burning house, we ought not, if it be full of smoke, to walk upright, for then we shall run the risk of suffocation. It is best to creep along on hands and knees, the freest air being to be had close to the floor. On being awakened by an alarm of fire during the night, it is particularly important to preserve presence of mind, and not to act till a moment has been taken for reflection. Preservation may depend on the choice we make of going up or down stairs, or on some selection of movement equally unimportant in ordinary circumstances of non-alarm.

**Fire-Escapes.**—The escape from a house which is on fire is sometimes prevented by the stairs being of wood, and either burning or already destroyed. In such an emergency, there are only two means of escape—issuing by the skylight, and so reaching the next house, or going over the window. On this account every house with wooden stairs should have a skylight, accessible from the upper floors, and also some kind of apparatus for getting safely from the windows to the ground. The apparatus which meets with most general approbation is a rope-ladder, and this may be made in different forms. Captain Manby recommends 'a rope with nooses, distended by flat rests for the feet at convenient distances for stepping from one to another. In cases of danger, this might be instantly fastened by one end to a table or bed-post, while the other is thrown out of the window, thus furnishing a ready escape when perhaps there is no other possible means near those who are in momentary dread of being burnt to death.' Such a ladder may be serviceably kept by private parties; and we should advise that at all events every house with wooden stairs ought to be provided with one or more pieces of knotted rope, and these be deposited in the bedrooms, for use when suddenly required. Where, from carelessness, no fire-escape of this kind has been provided, two or more sheets or blankets taken from the bed may be tied to each other by the corners, and thus a rope of sheet be formed. There is no instance on record of a person being burnt to death in Edinburgh by fires in dwellinghouses, although the buildings are more than usually high; the reason of which is, that there the stairs are all of stone. Every fire-establishment in towns, besides fire-engines and buckets, should possess several long ladders, ready at all times to be applied to windows; also cords,

which may be brought to bear wherever they are required. Portable ladders on the telescope principle are now not uncommon in our large towns.

**Ventilation and Fumigation.**—It is essential to health that the habitations occupied by us should be free of impure air and all noxious vapours. The first step towards this end is to effect and maintain a liberal circulation of fresh air, either by ventilators or by regularly opening the windows for stated daily periods. The kindling of fires also promotes the circulation of atmospheric currents. Noxious effluvia may be most effectually removed by occasional sprinklings of a solution of chloride of lime upon the floors and walls, the windows being kept open the while. It is always proper also that an infected house should be whitewashed. We have seen recommendations to purify the air of rooms by closing them, and burning salt and oil of vitriol in a dish placed on the floor. In unskilful hands such plans are highly dangerous; and we strongly advise every one to confine the fumigating process to sprinkling with chloride of lime, and to ventilate by opening all outlets to the air. Lives are sometimes lost by sleeping in a close room in which charcoal is burning, the person in this case being stifled with noxious gas. We advise that every sleeping apartment should be airy, and that no one should go to bed with charcoal burning in the grate or stove. Bedrooms are always best without fires of any kind.

**Disinfectants and Deodorisers.**—These, as their names import, are agents employed to destroy noxious and offensive effluvia. The principal, according to Mr Cooley, 'are chlorine, the chlorides of lime and soda, the fumes of nitrous and nitric acids, heat and ventilation. The last two are the most efficient and easily applied. The clothing, bedding, &c. of patients labouring under contagious diseases may be effectually disinfected by exposure to a temperature of about that of boiling water. Neither the texture nor colour of textile fabrics are injured even by a heat of 250 degrees Fahrenheit. It is a practice at some of the workhouses to bake the clothes of the paupers who have the itch, or are infested with vermin. Quicklime rapidly absorbs carbonic acid, sulphuretted hydrogen, and several other noxious gases, and is therefore commonly used as a wash for the walls of buildings. Acetic acid, camphor, fragrant pastilles, cascarilla, and other similar substances, are frequently burnt or volatilised by heat, for the purpose of disguising unpleasant odours. The sulphates of iron and lime have the property of rapidly destroying noxious effluvia. A quantity of either of these sulphates thrown into a cesspool, for instance, will in a few hours remove the fetid smell.'

**Alarms in Churches and Theatres.**—Alarms, whether with reference to fire or the falling of galleries, often take place in these and similar places of resort. In general they are raised without due cause, often from a circumstance of the most trifling nature, and perhaps occasionally from a deliberate spirit of mischief. However originating, they almost invariably generate a panic, and occasion much damage, which a little reflection would have enabled those present to avoid. The newspapers teem with accounts of incidents of this nature. In most instances the whole mischief is caused by *yielding too easily to alarm*. We anxiously recommend every one to cultivate the power of suppressing such idle emotions. When a cry of fire, or of the falling of galleries, is raised in church, *sit still*, and remain tranquil till the assemblage is allowed to disperse in the usual way. On no account yield to alarm. Granting that there is a real cause of danger, you are infinitely more safe sitting still than trying to rush wildly to the door.

**Attacks of Madmen.**—A person in a house may become suddenly insane, and make a violent and deadly attack on those within reach. The best way to avert any serious calamity in cases of such attack is to remain calm and collected, and, if necessary, humour the madman till assistance be procured. A lady of our acquaintance kept a boarding-house, and one day a

boarder entered the room in which she was sitting, armed with a carving-knife, and with great coolness said he had taken a fancy to cut off her head. The lady was alone. She saw her extreme danger, but did not scream or appear alarmed, for that would have precipitated the catastrophe. She humoured the madman, and proposed that she should go and fetch a cloth to lay on the floor, so as to prevent the blood from damaging the carpet. This bait took, and she got safely out of the room, and into her bed-chamber, in which there was a key in the door in the inside. She instantly locked the door, and flying to the window, cried for help to the passengers in the street. The madman was speedily secured. In this instance the lady clearly owed her life to presence of mind.

We would add, *let every door in a house have its key*, and let the key remain in it both night and day. Every night, on going to bed, isolate each room, by locking it, and lock your own door in the inside. Always look beneath the bed and into any cupboards in the room before going to rest.

**Coach Accidents.**—Should the horses run off, in defiance of all restraint, while you are in a coach, sit perfectly still; and in anticipation of the possible overturn, keep your legs and arms from straggling. Sit easily and compactly, so that, when upset, you will gently roll over in the direction you are thrown. We have seen ladies in these circumstances scream wildly, and throw their arms out of the windows, thus exposing themselves to the chance of broken limbs. If run away with in a gig, either sit still collectedly, or drop out at the back, so as to fall on your hands. Never jump from a rapidly-moving vehicle, unless (supposing it impossible to alip down behind) you see a precipice in front, in which case any risk of personal damage is preferable to remaining still. The Duke of Orleans [son of Louis-Philippe] lost his life by neglecting these simple precautions.

[For further information on the subject of accidents and emergencies consult No. 48, Vol. I.]

MANAGEMENT OF FUEL AND WATER.

**To light a Fire**, clear the ashes from the grate, leaving a few cinders for a foundation, upon which put a piece of dry crumpled brown paper, and lay on a few small sticks crosswise, then some of larger size, and on them a few pieces of coal, and next the large cinders; and when the flames have caught the coal, add a backing of small coal and cinders. When the fire has become low, stir it together, but do not turn the large cinders; clear the front of the lower bar to admit air, and pass the poker into the bottom of the fire to clear it of ashes; and then with tongs put on a few large pieces of coal towards the front of the fire, but not on the upper bar, else the fire will smoke. Coals should not be thrown on, but put on gently with a scoop or shovel; and even the smallest ashes may be burnt at the back of the fire, if they be covered with small coal. The best and quickest mode of restoring a neglected fire is to stir out the ashes, and with the tongs to fill up the spaces between the bars with cinders. If carefully done, it is surprising how soon this process will produce a glowing fire. A very effective firelighter or reviver, composed of sawdust and coal-tar, is now to be had in the shops for the merest trifle.

**Economical Fuel.**—In places where coal is scarce and dear, a tolerably good fuel may be made by mixing the culm or refuse dross of coal with clay, and moistening the whole with water—masses in the form of bricks or balls may be made, which, when dry, will burn with an intense heat. Where peat prevails, that article may be easily charred by burning in a covered pit or stove; and this charred peat will be found to give a great heat when used in an open fire. The Dutch make much use of their turf in this manner. Another economical fuel, easily procurable where there are woods of Scotch fir, consists of fir cones or tops, which contain a great quantity of solid woody matter in addition to the resinous, and are excellently adapted for domestic fires. Ashes

## HOUSEHOLD HINTS.

and small cinders mixed with water into a mass, and put on the back of a fire with a few coals, burn well, so that ashes may thus be entirely burnt up. In stoves under boilers, this mixture is very useful, as it lasts long, with little addition.

**Smoky Chimneys.**—The causes of smokiness in chimneys are various; but all are connected with the properties of air and heat, for the smoke is only particles of culm ascending through the agency of heated air. To make a chimney vent well, the column of heated air from the fire must not be entangled with cold air from beneath, nor retarded by cold air coming down the chimney. To effect these objects, the fireplace must not be much larger than the grate, and the chimney must be of a certain length and bent. The great leading cause of smokiness is cold air somehow or other mixing with the warm air about the mouth or throat of the chimney, and so causing a sluggishness in the ascent, or no ascent at all. Therefore the nearer the air is made to pass the fire on all sides, the more rarefied it will be; and the less vacancy there is in the chimney-place, it will ascend with the greater rapidity. A proper contraction of the mouth of the chimney, at the same time allowing the fire to be fed freely with air, will be found in most instances to cure smoke. Of late, certain contrivances called 'dampers,' by which the chimney throat can be narrowed, have been the means of effecting draughts, and so curing smoke. It should be noted, that in contracting chimney throats, the contraction should not be all at once, but at first gradual, and then straight upward, so as not to allow a volume of cold air to lurk in a hollow above. A chimney being wide at bottom, and gradually narrowing towards the next storey, allows the coldish air to hang about the lower parts, by which, when a gust of wind comes, the smoke is driven back into the room. This kind of smokiness is the most teasing of all the forms of chimney diseases. Every little puff of wind sends a smaller or larger quantity of smoke into the apartment, and often when it is least expected. Perhaps this kind of smokiness is not in all cases caused by wrong construction, but arises from the situation of the house; and of this we shall immediately say a few words.

If a funnel of a chimney be made too narrow to afford an easy passage to the top, the smoke will then naturally be forced into the room to find some other passage; this defect is very common, and the remedy troublesome and difficult. The most effectual cure, if the situation will admit, is to build a small additional flue, and open a hole into it from the back of the chimney, near the level of the mantelpiece, slanting upwards in an easy direction; this supplemental flue must be carried to the top of the building, to receive the surplus of the smoke, and will prove a certain cure. If the situation will not allow of this expedient, the fireplace may be contracted both in breadth and height, a smaller grate used, and the chimney heightened at the top; which will oblige the air to pass close over the fire, and carry up the smoke with greater rapidity; for the quicker the current, the less room it requires. Should the chimney still smoke, a blower, or front-plate, to put on and take off at pleasure, will be of use. But if none of these prescriptions answer, then something must be done to improve the current of air towards the fire. This brings us to a consideration of the want of sufficient ventilation in the room.

If the chimney and fireplace be faultless, and yet smoke, it is almost certain that there is a want of ventilation. In ordinary circumstances, as much air is admitted by chinks in windows and doors as will feed a fire; but if the room be rendered very close by closing as many chinks as possible, how is the fire to receive air? According to the plan on which houses are generally built, ventilation is left to be a matter of chance. To ventilate an old house is therefore no easy task. The following plans are worth considering, for they have been found to answer:—Contrive to bring a small tube from the external air, or from a staircase or lobby, to a point beneath the grate, so as to cause a free cur-

rent of air to reach the fire. If the mouth of the tube below the grate be topped with a cowl, the ashes will be prevented from falling into it. Some years ago, the rooms of a public office in Edinburgh were completely cured of smoke by this simple contrivance, after all other means had failed. Another plan consists in perforating small holes in the cornice or roof, for the air to gain admission; but, unfortunately, unless care be taken to prevent colds, this species of cure is apt to be worse than the disease.

Cases are by no means uncommon of fireplaces giving out a puff of smoke every time the door of the room is shut. The cause of this kind of smokiness is the want of ventilation in the room. In shutting the door, it pulls out a certain quantity of air, which cannot be afforded to be lost, or it causes such distraction of the current towards the fire, that the equilibrium that carries up the smoke is destroyed, and a puff downwards—in other words, a rush of air, loaded with smoke from the chimney—is the consequence. It will be remarked that this smokiness occurs most frequently when the door is on the same side of the room as the fireplace. We should therefore advise house-planners to avoid this bad arrangement. If possible, let the door be on a different side from that in which the fire is placed. Most houses in which the chimneys go up the middle walls instead of the gables, have the fault we mention. A remedy for this smokiness is to contract the mouth of the chimney, and, if possible, heighten the stalk; for if the chimney be pretty long, the heated air ascending it goes with such a force that the outer heavy air cannot get down, at least not to so great an extent as to cause a puff when the door is shutting. In some cases the cause of the disease will be found to be air rushing up behind the grate, if a register, and then coming down to supply the fire, the action of the door disturbing the current. This is therefore an argument for always taking care to build register stoves quite close behind, not leaving the smallest crevice for air to steal up the chimney without first going through the fire.

In erecting chimneys, it should be a rule to carry them up a good way in a perpendicular direction before making a turn, by which means the heated air gains a force in its primary vertical ascent which carries it over future difficulties. In walls in which the fireplace of one storey is immediately below the fireplace above, it is impossible to get a perfect straight for any great length; therefore this must be left to the judgment of the builder. It is also advantageous for all chimneys to have a bend in them before reaching the top, and a garret chimney should have two bends. For want of attention to this top bending, many cottages and small villa chimneys smoke. The use of bends is obvious: strong, sudden, and accidental gusts of wind sometimes enter, and beat into the top of the chimney; a turning or bend, therefore, will break the force of the wind, and prevent it repelling the heated air downwards. But if the chimney is straight, and the gust meet with no interruption, it will stop the passage of the smoke for a while, and of course force what rises from the fire immediately into the chamber. It is to be observed, that the farther the wind gets down the funnel, the greater strength will be required to repel it; therefore the nearer to the top the bend or winding is the better. Also, if there is a storm of wind, with heavy showers of hail, snow, or rain, falling perpendicularly in great drops, the first bend or turning will, in part, stop their progress; but if the funnel is perpendicular all the way down, the great drops of hail, snow, and rain, will fall freely to the bottom, repelling the smoke into the room; and if the funnel is foul, great quantities of soot will be driven down. These considerations recommend a bend in some part of the funnel as absolutely necessary.

Garret chimneys are more liable to smoke than any other in the house, owing to the shortness of the funnel: for when the composition of rarefied air and smoke has made its way up a high funnel, it forms a strong

column, and to repel it requires a proportionably great force; but in a garret chimney this strong column cannot be obtained; therefore what cannot be had from nature must be aimed at by art. The fault in most garret chimneys is, being carried up in a straight direction from bottom to top in a slovenly manner, and with funnels as large as any in the house; whereby the little internal rarefied air has the whole immediate pressure of the atmosphere to resist, which in general is too powerful for it. But a garret or cottage chimney carried up and executed in a proper manner, with due proportion in every part, according to the size of the room, and the funnel in an easy crooked direction, will draw and be as clear from smoke as any other.

When smokiness is produced by too short a chimney, it will be necessary to add to its length either by building the stalk higher, or inserting an earthenware pot or iron tube at the summit. The building of higher stalks is an infallible remedy, provided all be right below; but it is attended with danger to adjoining roofs. Pots or cans are useful both in adding to height, and in causing a free disengagement and shooting of the smoke as soon as it enters the outer atmosphere.

Another very common cause of smokiness is fires overpowering one another. For instance, if there be two chimneys in one large room, and you make fires in both of them, the doors and windows close shut, you will find that the greater and stronger fire shall overpower the weaker, and draw air down its funnel to supply its own demand; which air descending in the weaker funnel, will drive down its smoke, and force it into the room. If, instead of being in one room, the two chimneys are in two different rooms, communicating by a door, the case is the same whenever that door is open. In a very tight house, it has been known that a kitchen chimney on the lowest floor, when it had a great fire in it, has overpowered any other chimney in the house, and drawn air and smoke into its room as often as the door was opened communicating with the staircase. The remedy for this is, to take care that every room in a house has the means of supplying itself with what air it requires, so that it does not need to borrow air from other rooms. Back smoke is only cold air loaded with smoke coming down into a room from an adjoining chimney-top, in order to supply, in the readiest manner, air to that room. Thus fires in the lower part of a house will draw air even from a garret room, and this garret room will draw air to supply its deficiency, by taking it in a smoky condition from the adjoining chimney tops.

Smokiness is also produced when the tops of chimneys are commanded by higher buildings, or by a hill, so that the wind blowing over such eminences falls, like water over a dam, on the tops of the chimneys that lie in its way, and beats down the smoke contained in them. Sometimes we have seen the droll phenomenon—though it is no laughing matter—of every particle of smoke all of a sudden pouring into the room, in consequence of a gust of wind blowing pertinaciously for several minutes down the chimney. Such a form of smokiness arises chiefly from the situation of the house, and the want of a bend in the chimney. The remedy to be applied is fixing on the top of the chimney a turning cap or cowl, which acts like a weathercock, and keeps its closed side to the wind. These cowls, however, are creaking, noisy things; and being hence insufferable near sleeping-rooms, are only to be resorted to when more simple means have proved unavailing.

*Supply of Water*, whether for dietetic, domestic, or sanitary purposes, has been fully discussed in a previous number (30). The chief care of the housewife is, that she has a sufficient, pure, and wholesome supply of this indispensable element. Where water for domestic purposes is obtained from open streams and pools, caution is always necessary, and especially during summer, when vegetable and animal impurities are most abundant. Pump-wells also require to be looked after, especially if they have stood without

being used for a time. Where service-pipes are admitted into a house, care is necessary—1st, To see that the stopcocks are always secure, as frequently great damage is occasioned to furniture and ceilings by waste water; 2d, That cisterns be regularly cleaned, and if of lead, that they be not scoured, but simply sluiced out; and, 3d, That during severe frosts the stopcocks of exposed pipes be allowed to discharge a little, as the flow of water prevents freezing and consequent bursting of the pipes.

*To purify Water*, a vast number of means may be adopted, according to the nature of the impurities:—1. Water may be sweetened and improved by free exposure to the air. Pouring it at some height from a watering-pot into a flat vessel will answer this end. 2. Filtration or agitation with freshly-burnt charcoal, animal or vegetable, but especially the former, is an excellent method. 3. From fifteen to twenty drops of sulphuric acid to a gallon of water will produce a similar effect. 4. An ounce or thereby of powdered alum, dissolved and stirred into a hoghead of putrid water, will precipitate the foul matter in a few hours. 5. Red sulphate of iron, black oxide of manganese, or a little aqueous chorine, will produce the same effect. 6. Hard water may be softened by the addition of a solution of carbonate of soda or potash; by the same means sea-water may be rendered fit for washing.

*To filter Water*.—Put into an earthen vessel (such as sugar-bakers use to form the loaves in, with a small hole at the bottom or pointed end) some pieces of sponge, and on them a sufficient number of small clean pebbles to quarter-fill the vessel. Hang this filter end downward, in a barrel with the head out, leaving a space of about two or three inches between the end of the filter and the bottom of the barrel. The upper part of the filter should be kept a little above the top of the barrel, which must always be kept full of water. The sediment of the water will remain at the bottom of the barrel, and the pure water will rise through the sponge and pebbles to the vacant part of the filter. It may be hung in a cistern, or water-but if more convenient. The pebbles and sponge should be cleansed occasionally.

Another economical filter may be made by taking out the head of a cask, setting it upright, and at a distance of about one-third from the bottom putting in a shelf or partition pierced with small holes; this shelf being covered with pebbles, upon which is a layer of fresh charcoal made from bones; and over this lay fine sand, to the depth of an inch, covered with another layer of pebbles; and upon this should be placed another shelf, pierced with holes, to prevent the pebbles, sand, and charcoal being disturbed by the water which is poured or runs in at the top of the cask; and after passing through the filter, is drawn off by a crane placed at the bottom of the cask.

Portable and very efficient earthenware filters may be had at the shops, varying in price from 8s. to 30s., according to size and quality. We have used one of Sotheran's No. 2 for several years, and have found it to answer the purpose to perfection. For information respecting filtration on a large scale, see SUPPLY OF WATER, Vol. I., page 472.

*Tests for Water*.—Mechanical impurities, or such as are suspended in water, may be removed by rest or filtration, as above described; but chemical impurities, or such as are dissolved, pass through the filter, which has no power of separating them. When *lime* in any form is present, oxalic acid or oxalate of ammonia will cause a white precipitate. Carbonate of iron may be detected by the tincture of galls, which causes a black precipitate. If *copper* is present, the blade of a penknife dipped in the water will assume a yellowish coating. *Vegetable* and *animal matter* may be detected by sulphuric acid, which blackens the water.

#### SMALL DOMESTIC MANUFACTURES.

The attempt to make all sorts of articles for domestic use is now far from economical, as the time and expense bestowed upon them are often of greater amount

## HOUSEHOLD HINTS.

than what would buy the things ready-made from shops. We therefore confine our directions to articles which may require to be manufactured in families at a great distance from towns, or for the families of emigrants in remote settlements.

**Blacking for Shoes.**—There are many ways of making this article, the chief ingredients employed being ivory-black, vinegar or sour beer, sugar, a little sweet-oil, and oil of vitriol. A good blacking may be made as follows:—Mix three ounces of ivory-black, two ounces of treacle, a tablespoonful of sweet-oil, one ounce of vitriol, one ounce of gum-arabic dissolved in water, and a pint of vinegar.

For **Blacking-Balls**, mix one pound of ivory-black, one pound of lampblack, a quarter of a pound of gum-arabic dissolved in water, six ounces of brown sugar, half an ounce of melted glue, and a quart of water; and make into balls. A fine blacking for dress-shoes may be made by well beating two eggs, and adding a tablespoonful of spirits of wine, a lump of sugar, and ivory-black to thicken. This blacking may also be used for restoring the black leathern seats and backs of chairs, &c. It should be laid on and polished as other blacking, and then left a day to harden.

**Boot-top Liquid.**—Dissolve in a quart of water one ounce of oxalic acid, and the same of white vitriol; with which sponge the leather, previously washed with water; then wash off the composition with water, and dry. This mixture is for *white* tops. For *brown*, mix one ounce of oxalic acid, one ounce of spirits of salts, a scruple of cochineal bruised, and a pint of boiling water, and use as above. These mixtures should be labelled 'poison.' For brown tops, also, mix with a pint of skimmed milk half an ounce of spirits of salts, half an ounce of spirits of red lavender, one ounce of gum-arabic dissolved in water, and the juice of two lemons; keep the mixture closely corked, sponge the tops when dry, and polish them with a brush.

**Blacking for Harness.**—Melt two ounces of mutton-suet with six ounces of bees'-wax; add six ounces of sugar-candy, two ounces of soft soap dissolved in water, and one ounce of indigo finely powdered; and when melted and well mixed, add a gill of turpentine. Lay it on the harness with a sponge, and polish off with a brush.

**Paste** is useful in a house for papering walls, cupboards, boxes, labelling, &c. A very useful composition of this sort is made of flour in the usual way, but rather thick, with a proportion of brown sugar, and a small quantity of corrosive sublimate. The use of the sugar is to keep it flexible, so as to prevent its scaling off from smooth surfaces; and that of the corrosive sublimate—independently of preserving it from insects—as an effectual check against its fermentation. This salt does not, however, prevent the formation of mouldiness; but a drop or two of oil of lavender, peppermint, or aniseed, is a complete security against this.

**Waterproof stuff for Shoes.**—In winter, or during wet weather, shoes may be rendered durable by applying to the soles and seams a composition made of the following materials:—Half a pint of unboiled linseed-oil, two tablespoonfuls of turpentine, one ounce of bees'-wax, and a quarter of an ounce of Burgundy pitch. Melt the whole together, and apply with a brush before the fire. Repeat the application till the soles will absorb no more. Neats'-foot oil alone will be found an excellent preservative of shoes in wet weather. Since the introduction of caoutchouc and gutta-percha, waterproof stuff for shoes and goloshes can be readily obtained at the shops, fitted or worked up in the household. Any one may sole his own shoes for a shilling.

**Bottle Wax.**—A good kind of bottle wax or cement may be cheaply made as follows:—Put into an iron ladle half a pound of rosin, two ounces of bees'-wax, and when melted over the fire, stir in Venetian red, lampblack, or other colouring; and apply while hot. If kept for after-use, melt with a candle, as usual, when applied.

**Potato-Starch.**—Wash and peel a gallon of good potatoes, grate them into a pail of water, stir frequently, and

then let them settle. On the following day the starch will be found at the bottom of the pail; when pour off the water, add fresh, stir as before, and let it subside a second time; when pour off the water, and dry the sediment in the sun or a slow oven. An excellent starch may also be made by setting in a cool place the water in which rice has been boiled (though not in a cloth), which will in twenty-four hours become a strong starch.

**Potashes.**—Settlers in the backwoods of America, or other woody regions, have an opportunity of manufacturing potashes, an article of great use, and considerable value. A vast quantity of this substance is annually made in Canada, and exported to Great Britain. Potashes are made from the ashes of burnt trees. In burning timber to clear the land, the ashes are carefully preserved, and put in barrels, or other vessels, with holes in the bottom; and water being poured over them, a liquid or alkali is run off. This lye being boiled in large boilers, the watery particles evaporate, and leave what is called black salts, a sort of residuum, which, when heated to a high degree, becomes fused, and finally, when cool, assumes the character of potash. By these potashes the Canadians make their own soap: the lye of a barrel of ashes, boiled along with ten pounds of tallow, till it is of a proper consistence, produces about forty pounds of very good soft soap. It is related, that when the land has been covered with heavy timber of a hard nature, there is such a quantity of ashes produced, that their value is sufficient to pay for the clearing of the land.

**Ash-Balls.**—This term is applied to the ashes of various plants, especially ferns, moistened, and made into lumps or balls. They are used as a substitute for soap, and to clean painting.

**Dyes.**—The most simple rule for dyeing is, to put the dye into very hot water, and when well mixed, to pass the stuff through it until it sufficiently imbibes the colour, but on no account to squeeze it: it should then be hung up, and when cold, plunged twice into soft water, and then into hard water with a little alum dissolved in it: the stuff may then be again hung up, and when nearly dry, ironed or pressed. Most colours are made brighter by the addition of a little cream of tartar, and darker by pearl-ash. Dyes may be purchased ready prepared. We would recommend that all ordinary dyeing, and particularly when fancy or delicate colours are required, should be consigned to the hands of the professed dyer; and dyeing of a coarse kind only be done at home. In such cases, *brown* may be produced from a decoction of birch bark; and *black* from logwood with green copperas (see article CHEMISTRY APPLIED TO THE ARTS).

**Bleaching small Articles.**—The principles and practice of bleaching cotton, linen, and woollen on a large scale have been detailed in Nos. 20 and 22; we here allude to minor articles, which may be whitened in the laundry or kitchen. Silk is bleached by boiling it in white soap and water, to remove the natural yellow varnish which covers it; after which it is subjected to repeated rinsings. Articles that are required to be very white—as gloves, stockings, &c.—are also submitted to the action of sulphurous acid, or to the fumes of burning sulphur. Straw is also bleached by the fumes of sulphur; hence arises the sulphurous smell emitted by new strawhats and bonnets. They may, however, be bleached in a much better manner by the use of a little oxalic acid, or chloride of lime. Printed books, engravings, &c. may be whitened by first subjecting them to the action of weak chloride of lime-water; next to water soured with sulphuric acid; and lastly, to pure water, to remove any adhering acid or chlorine.

**Clothes-Balls** for removing grease and stains may be made as follows:—Fullers'-earth, two pounds; curd soap, one pound; ox-gall sufficient to make a stiff dough, with which form balls. Or—pipeclay, two pounds; fullers'-earth, one pound; whitening, one-half pound; white pepper, three ounces: mix with water. What are called **Scouring-Balls** are either composed of soft soap and fullers'-earth in equal proportions, beaten

well together, and formed into balls; or of curd soap, oil of turpentine, and ox-gall, in the proportion of half a pound of soap to one ounce of the turpentine and one ounce of the gall. *Wash-Balls*, again, are generally made of white curd or Windsor soap beaten up with bole or ochre; the mottled colours being produced by using a mixture of red, blue, or other coloured boles.

*Cloth, Incombustible*.—Cotton and linen fabrics prepared with a solution of sal-ammoniac, or phosphate of ammonia, may be placed in contact with ignited bodies without danger: they will carbonise, but not inflame. Solutions of alum, sea-salt, and the like, are used for the same purpose. If, for instance, an ounce or half an ounce of alum or sal-ammoniac be added to the last water used in rinsing a lady's dress, it would render it incombustible, or at least so little combustible that it would not take fire readily; and if it did, would be consumed without flame.

*Temperance Drinks*.—The simplest beverage of a cooling and pleasing quality, which contains no intoxicating fluid, is *lemonade*; this may be very easily made by pouring boiling water on sliced lemons, and sweetening with sugar to taste. Lemons, however, are not always to be procured, and in such a case citric acid, or cream of tartar, may be employed instead. Superior lemonade is made with lump-sugar.—*Ginger-Beer* may be made as follows:—Take of lump sugar three pounds, bruised ginger two ounces, cream of tartar one ounce, one or two lemons sliced, boiling water four gallons, and yeast eight ounces. Let the whole stand to work in a cask for four days, and then bottle off for use.—*Spruce-Beer*, which is a pleasant beverage when well prepared, and possesses slightly diuretic properties, may be prepared as follows:—Water, ten gallons; sugar, ten pounds; essence of spruce, quarter of a pound; yeast, half a pint. Dissolve the sugar and essence of spruce in the water, previously warmed; then allow it to cool a little, and add the yeast as in making ginger-beer: bottle immediately.

*Treacle-Beer* is a cheap drink, which may be made as follows:—Boil as much water as will fill twelve common quart bottles; and to it add one pound of treacle, or more, according to taste. When the treacle is dissolved, take the pot from the fire, and let the solution cool. When lukewarm, put into it half a gill of yeast. As soon as it is cold, bottle it, but do not put in the corks till next morning, when the yeast will have wrought over the top of the bottles. Let it stand in a cool place for two or three days, when it will be fit for use. Unless care is taken as to the proportion of yeast, and keeping cool, also to corking tightly, the bottles may burst, which is a serious loss to a poor family.

MISCELLANEOUS HINTS AND RECIPES.

*To remove a tight Stopper*.—It frequently happens that the stopper of a glass bottle or decanter becomes fixed in its place so firmly, that the exertion of force sufficient to withdraw it would endanger the vessel. In this case, if a cloth be wetted with hot water, and applied to the neck of the bottle, the glass will expand, and the neck will be enlarged, so as to allow the stopper to be easily withdrawn. Where hot water is not at hand, the same result may be produced by the friction of a handkerchief or strip of flannel, passed round the neck of the bottle, and drawn backwards and forwards with a see-saw motion.

*Adhesive Plaster*.—A very useful adhesive plaster may be made by melting together five parts of common or litharge plaster with one part of white resin. The mixture, when well incorporated, is spread on thin strips of linen with a spatula or table-knife. Such a plaster may be advantageously employed for keeping on other dressings, where ligatures and bandages might be objectionable.

*Cutting Glass*.—Panec or flat pieces of glass may be divided, when a glazier's diamond is not at hand, by making a notch with a file, and carrying a piece of hot charcoal in the line in which it is wished the fracture should proceed. The charcoal must be kept alive

by blowing upon it with the breath. A red-hot iron will also do. Vials, bottle-necks, and the like, may be cut across by looping a cord round the part where the fracture is wanted, drawing the cord rapidly backwards and forwards till a considerable degree of heat is produced by the friction, and then immersing in cold water up to the line of fracture. The rapid and unequal contraction of the parts will cause the glass to snap asunder.

*Mending China and Earthenware*.—When holes are required to be drilled in china or earthenware for the purpose of riveting it when broken, procure a three-cornered file, and harden it completely by making the end red-hot, and plunging it into cold water; then grind the point quite sharp on a grindstone, and afterwards on an oil-stone or hone. With the point of this tool pick repeatedly on the spot to be bored, taking care not to use too much violence, lest the object should break. In a short time, or in a few minutes, by a continuance of the operation, a small conical hole will be forced out, not bigger than a pin's head, but which may afterwards be widened by introducing the point, and working the file round. Rivets of lead are those generally employed in this kind of operation.

The best cement for broken china or glass is that sold in the shops under the name of diamond cement, which is colourless, and resists moisture. This is made by soaking isinglas in water till it is soft, and then dissolving it in proof spirit. Add to this a little gum-ammoniac, or galbanum and mastic, both dissolved in as little alcohol as possible. When the cement is to be used, it must be gently liquefied by placing the vial containing it in boiling water. The vial must be well closed by a good cork, not a glass-stopper, as this may become fixed. It is applied to the broken edges with a camel-hair pencil.

When the objects are not to be exposed to moisture, white of egg alone, or mixed with finely-sifted quick-lime, will answer pretty well. Shell-lac dissolved in spirits of wine is better. A very strong cement for earthenware is made by boiling slices of skim-milk-cheese with water into a paste, and then grinding it with quicklime in a marble mortar, or on a slab with a mallet. [For further information on the subjects of lutes and cements, see No. 21.]

*To remove Crust or Fur from Teapots*.—Put a good-sized lump of common soda into the pot, fill it quite full with boiling water; let it remain in the whole of a day and night; and, to keep the water hot for a time, set the pot near the fire. Should a teapot spout have become furred, when the water has been in for a sufficient length of time, put a skewer or knitting-needle into the spout to clean it. It will afterwards be necessary to scald and well wash the pot, to prevent any taste of soda, and to remove the fur, which will then come away easily.

*Bronzing*, or the process of imparting to wood, iron, stucco, or other material, the appearance of bronze, may be readily practised by attending to the directions given in Vol. I., p. 378.

*Sympathetic Inks*.—These are preparations used for writing on paper, the marks of which are invisible until acted upon by some re-agent. They are frequently employed in secret or playful correspondence. By heating the paper until it is nearly scorched, they may be rendered visible. The following may serve as specimens:—

1. Sulphate of copper and sal-ammoniac, equal parts, dissolved in water—writes colourless, but turns yellow when heated.
2. Onion juice—like the last.
3. A weak infusion of galls—turns black when moistened with weak copperas water.
4. A weak solution of sulphate of iron—turns blue when moistened with a weak solution of prussiate of potash—black with infusion of galls.
5. The diluted solutions of nitrate of silver and terchloride of gold—darken when exposed to the sunlight.
6. Aquafortis, spirits of salts, oil of vitriol, common salt, or saltpetre, dissolved in a large quantity of water—turn yellow or brown when heated.
7. Solution

## HOUSEHOLD HINTS.

of nitromuriate of cobalt—turns green when heated, and disappears again on cooling. 8. Solution of acetate of cobalt, to which a little nitre has been added—becomes rose-coloured when heated, and disappears again on being cooled.

**Incorrodible and Indelible Inks.**—Genuine asphaltum, one part; oil of turpentine, four parts; dissolve, and add lamp-black or black-lead to bring it to a proper consistence. Or—Asphaltum, one part; oil of turpentine, four parts; dissolve, and colour with printer's ink, which any printer will sell by way of favour. These inks supply a cheap and excellent material for marking linen, &c. They are very permanent. They should be employed with stamps or types, or with the thin brass plates with letters cut therein. This method of marking is neater and easier than with the brush or pen. The marking-inks of the shops generally consist of preparations of nitrate of silver; but though capable of withstanding ordinary washing, are by no means proof against chlorine and ammonia. One of these inks may be prepared as follows:—Nitrate of silver, one to two drachms; water,  $\frac{3}{4}$  of an ounce; dissolve; add as much of the strongest ammonia water as will dissolve the precipitate formed on its first addition; then further, add mucilage one or two drachms, and a little sapphire green to colour. Writing executed with this ink turns black on being passed over a hot Italian-iron.

**Common Inks and Writing Fluids**, for which there are so many receipts, can be obtained so cheaply, and of such excellent quality, that it would be waste of time to attempt their manufacture for domestic use. An excellent ink, suitable for writing with steel pens, which it does not corrode, may be made of the following articles:—Sixty grains of caustic soda, a pint of water, and as much Indian ink as you think fit for making a proper blackness. Copying ink is prepared by adding a little sugar to ordinary black ink.

**Writing rendered illegible by age may be restored** by moistening it by means of a feather with an infusion of galls, or a solution of prussiate of potash slightly acidulated with muriatic acid, observing so to apply the liquid as to prevent the ink from spreading.

**Lucifers** may be made by first dipping thin slips of fir-wood in melted sulphur, and then tipping them with a mixture of sulphuret of antimony and chlorate of potash (both in fine powder), made into a paste with a solution of gum. They are inflamed by friction against a piece of emery or sand-paper. They are now sold so cheaply, that it would be folly to attempt their manufacture on a small scale.

### CABINET COLLECTIONS.

**Taxidermy**—so called from the Greek *taxis*, order, and *derma*, skin—is the art of arranging, preparing, and preserving the skins and other exuviae of animals, so as to represent their natural appearance. It embraces the entire art of preparing the skins of quadrupeds, the stuffing of birds and fishes, the mounting of insects, the cleaning and arranging of shells and zoophytes—in fine, the preparation and preservation of specimens in every department of the animal kingdom. Much of this lies of course beyond the circle of domestic economy, but many persons who have cabinets so arranged, allow them to fall into ruin and disorder for want of proper cleaning and attention.—*Skins of quadrupeds and birds*, whether mounted or not, should be kept free from dust either by being placed in cabinets, in glass-cases, or under glass shades; when dusty, use bellows, and handle as little as possible. Arsenical soap, corrosive sublimate, and oil of turpentine, are the preservative preparations; and once a skin is thoroughly dried, it may be preserved from putrefaction by being kept dry afterwards. Small bags of camphor laid in cabinets assist in warding off moths and other insects; but even with this the specimens will require to be occasionally examined. Should insects have commenced their attacks on any specimen, the only chance of further preservation is to bake it thoroughly in an oven.—*Bones* which have lost their

whiteness may have it restored by immersion for ten or twelve hours in a weak solution of chloride of lime; and if oily, a little soda should be added to the solution. To obtain the skeleton of a small animal, bait the carcass with honey, and lay it near the nests of ants or wasps; in a few days it will be beautifully picked.—*Insects*, which are usually mounted on pins in flat trays with cork bottoms, or are kept in pill-boxes, test-tubes, and quills, require very delicate handling. Once in possession of a collection, keep it dry and free from dust, and disturb the specimens as little as possible, as they are not only extremely fragile, but are apt to lose the rich downy covering of their wings, which gives them colour and beauty. To ward off the attacks of mites, keep a supply of camphor, or sponge dipped in spirit of turpentine, in each tray; and if these harpies should appear, bake before a slow fire, or take equal parts of oil of anise, oil of thyme, and alcohol; mix, and apply a drop to the infected specimen. When large-bodied specimens become greasy, dip in spirits of turpentine, and dry with calcined magnesia, which can afterwards be blown off.—In collecting *shells*, kill the animal by gradual immersion in hot water; and remove it with the point of a knife or crooked pin. Retain the operculum of univalves; and tie the bivalves together after the animal has been removed. Marine shells should be steeped in fresh-water for several hours, to remove all saline matter which would afterwards deliquesce. Remove all extraneous matter, as sea-weed, serpule, and the like, with the knife or brush. Dead shells, or those picked up along shore, have often a tarnished appearance; this may be remedied by applying a little olive-oil with a brush. Polishing and whitening with acids is a barbarity worthy only of the dealer in curiosities. No shell is fit for a cabinet after such mutilation. Shells may be either kept in trays, divided into numerous compartments, or attached to cards with a little gum. In the latter case it requires two specimens—one to exhibit the front, the other the back of the shell. Minute and fragile shells are best preserved in glass tubes—common test-tubes.

**Minerals** are kept with little trouble, if dust be excluded. Never lift a fine specimen with the naked hand; stains of grease and perspiration are intolerable. Dust always with a pair of bellows. Certain species will endure washing; in other cases the appearance may be restored by fracturing anew.

**Drying Flowers as Specimens.**—A writer in the 'New Monthly Belle Assemblée' recommends the following plan:—'As pressure is necessary for drying flowers, the first thing requisite is to construct a press, which in this instance is composed of two of the thickest milled boards, each twenty inches in length and fourteen in width; also two leathern straps with buckles, and holes at intervals, to allow for the varying bulk of the press; then procure two quires of coarse sugar-paper, which can be purchased at a grocer's. After having selected the most perfect specimens of flowers, with their stems, lower leaves, and roots, when practicable—and carefully observe that the plants be free from dew or moisture—lay every portion out nicely on one of the coarse sheets, being careful at the same time that one part of the specimen does not interfere with another: the leaf should be filled. Allow several sheets to intervene before another sheet is occupied by specimens. If the flowers be delicate, their colour will be better preserved by placing blotting-paper between the folds to absorb the moisture. The plants are now ready to be put into the press, the straps forming the pressure, which, however, must not be great at first. It is necessary to remove the flowers every day, and dry the papers at the fire. When the specimens are quite dry, they should be taken from the press, and each plant separately sewed or fastened with gum on to half-sheets of foolscap; they may then be arranged in their natural orders, with the Linnæan class and order, and their place of growth, appended in the lower corners of the paper. The sheets thus classed

make up the Herbarium or *Hortus Siccus*, and are kept in trays, boxes, or in a cabinet constructed for the purpose, in a dry room, when they will be ready for future reference, which is the principal use to be derived from making a collection of plants. Those who can afford the expense, will find 'botanical paper' (a thick, absorbent paper) the best for drying their specimens; they will also find a bag of small-shot a more delicate and efficient presser than either straps, screws, or weights. In every case the plants ought to be thoroughly dried—that is, deprived of their natural sap—before they are finally assorted in the *Hortus Siccus*: if not, they will soon get mouldy, lose their hues, and become a bundle of useless rubbish.

*Marine Plants* (fuci and algae) may be preserved in a somewhat similar manner. After selecting the freshest specimens either from the rocks on which they grow, or from the beach on which they are generally profusely scattered after a storm, they ought to be well soaked in fresh-water, to remove all saline particles. This being done, they should next be floated in a broad shallow vessel, and the paper on which they are to be placed carefully inserted under them—gradually raising the paper, and disposing their filaments in a natural manner with the point of a bodkin or knitting-needle. This operation will be greatly facilitated by placing the paper on a thin board or plate of sheet-iron, so as to keep it smooth and level. When a specimen has been properly spread out, it should be laid aside to dry on a flat board or table; and finally subjected to proper pressure between milled boards. The natural mucus of the specimens will, in general, be sufficient to attach them firmly to the paper: if not, a slight touch of gum from a hair-pencil will answer the purpose. Sea-weeds neatly mounted and labelled make a very beautiful and instructive addition to the cabinet.

*Preserving Flowers Fresh.*—Flowers may be preserved in a fresh state for a considerable time by keeping them in a moist atmosphere. In the 'Gardeners' Chronicle' the following appear on this subject:—"It is now eighteen years ago since we first saw, in the drawing-room of a gentleman, in the hot dry weather of the dog-days, flowers preserved day after day in all their freshness by the following simple contrivance:—A flat dish of porcelain had water poured into it. In the water a vase of flowers was set; over the whole a bell-glass was placed with its rim in the water. This was a "Ward's case" in principle, although different in its construction. The air that surrounded the flowers being confined beneath the bell-glass, was constantly moist with the water that rose into it in the form of vapour. As fast as the water was condensed, it ran down the sides of the bell-glass back into the dish; and if means had been taken to enclose the water on the outside of the bell-glass, so as to prevent its evaporating into the air of the sitting-room, the atmosphere around the flowers would have remained continually damp. What is the explanation of this? Do the flowers feed on the viewless vapour that surrounds them? Perhaps they do; but the great cause of their preserving their freshness is to be sought in another fact. When flowers are brought into a sitting-room, they fade because of the dryness of the air. The air of a sitting-room is usually something drier than that of the garden, and always much more so than that of a good greenhouse or stove. Flowers, when gathered, are cut off from the supply of moisture collected for them by their roots, and their mutilated stems are far from having so great a power of sucking up fluids as the roots have. If, then, with diminished powers of feeding, they are exposed to augmented perspiration, as is the case in a dry sitting-room, it is evident that the balance of gain on the one hand by the roots, and of loss on the other hand by their whole surface, cannot be maintained. The result can only be their destruction. Now, to place them in a damp atmosphere is to restore this balance; because, if their power of sucking by their wounded ends is diminished, so is their power

of perspiring; for a damp atmosphere will rob them of no water—hence they maintain their freshness. The only difference between plants in a "Ward's case" and flowers in the little apparatus just described is this—that the former is intended for plants to grow in for a considerable space of time, while the latter is merely for their preservation for a few days; and that the air which surrounds the flowers is always charged with the same quantity of vapour, will vary with the circumstances, and at the will of him who has the management of it. We recommend those who love to see fresh flowers in their sitting-rooms in dry weather to procure it. The experiment can be tried by inserting a tumbler over a rose-bud in a saucer of water.'

#### PERSONAL ECONOMY—THE TOILET.

Personal cleaning and decoration are the proper duty at the toilet, which requires regular performance daily. We shall speak first of matters connected with the gentleman's toilet:—

*Shaving.*—Some beards are more hard and difficult to shave than others. The usual plan is to soften them with soap lather; but this is not sufficient with beards which are somewhat stubborn. We recommend all to try the following plan:—Rub the face or beard with a little soap and water with the hand over the basin, and when pretty well rubbed or softened, apply the lather. Raise the lather from warm water, and apply with a brush. The best kind of soap for shaving is Bandana, but Windsor is also generally liked. Among the shaving pastes in vogue the following may be mentioned:—1. White wax, spermaceti, and almond-oil, of each a quarter ounce; melt, and while warm, beat in two squares of Windsor soap, previously reduced to a paste, with rose-water. 2. Melt together a half-ounce each of spermaceti; white wax, and oil of almonds; beat it up with three ounces of the best white soap, and a sufficient quantity of Eau de Cologne. Although warm water is most agreeable and suitable for shaving with, it is advantageous for every one to accustom himself to shaving with cold water, as it will render him independent of such assistance when travelling, or in cases of emergency.

It is of no use going to a great expense in purchasing razors. A razor of the best kind may be had for from four to eight shillings; and as their tempering is very much a matter of chance, sometimes a first-rate razor may be had for two or three shillings. Indeed one of the very best razors now in the market is Rogers' 'old English,' which may be had for three shillings and sixpence. Supposing a sharp and good razor to be procured, it may last a whole lifetime with ordinary care. We have used one for twenty years, and it is still as good as new. Some persons prefer keeping six or seven razors, and changing them daily; but in this there is no absolute utility. Razors become blunt more from bad management than fair work in shaving. When to be used, dip the razor in hot water, for this adds keenness to the edge; and before putting it away, wash the razor gently, to remove all impurities. Do not wipe it with or upon paper, for that spoils the edge; wipe it only with a fine rag. Before putting it away in its case, give it a turn or two on a strop. Several kinds of strops are now offered for sale; and all, very properly, are mounted on hard board. The best we have seen is an American invention, with four sides of different degrees of fineness, from the hone to smooth stropping. In any case, take care always to draw the razor smoothly and flatly *from heel to point* along the strop. Do not draw first one way and then push another. In general, one or two turns will be enough. Never leave your razors in drawers or cases which are accessible to servants or children. By locking them up, you will keep them in better order than by all the other means you employ.

*Razor Pastes.*—This is the term applied to certain compositions applied to razor-strops to give them the necessary whetting surface. The following are recommended:—1. Emery reduced to an impalpable powder,

two parts; spermaceti ointment, one part; mix together, and rub it over the strop. 2. Jewellers' rouge, black-lead, and suet, mixed in equal parts. 3. Prepared putty-powder, one ounce; powdered oxalic acid, one-fourth ounce; powdered gum, twenty grains; make it into a stiff paste with water, and evenly and thinly spread it over the strop. With very little friction, this last is said to give a fine edge to the razor, and its efficiency is still increased by being moistened.

*Cut in Shaving.*—The bleeding may be at once effectually stopped by placing on the wound a small portion of wool from a beaver hat. We have known cases in which bleeding from very serious wounds have been stopped by the application of hat stuff, or fine floss, when all other means failed.

*The Teeth.*—The cleaning and proper management of the teeth is the most difficult operation of the toilet. Whether arising from heat of the stomach or other constitutional causes, the teeth of some persons are much more liable to become discoloured and decay than others. In general, even in the worst cases, much might be done in youth to prevent future deterioration of teeth; but children are ignorant, and parents are lamentably careless on this important matter of personal economy, and remedies often require to be applied when too late. Parents desirous of seeing their children grow up with good teeth, should cause them to be cleaned with scrupulous regularity daily, though only with a brush and tepid water. If the teeth appear crowded, so that there is a fear of one tooth shooting over another, a dentist ought by all means to be employed to thin the row, and allow all to grow straight.

The daily cleaning of the teeth should take place every morning after washing the face. Employ in preference tepid water and a moderately hard brush, taking care not to injure the gums by the friction. Various dentifrices or powders are offered for sale, and which the opulent have opportunities of testing; but we know of none better than finely-powdered charcoal—that is, charred wood well ground in a mortar, and kept in a box secluded from the air. It may be purchased, ready for use, at a small price from perfumers. By putting a little of this on the wet brush, and rubbing the teeth with it, impurities and discolorations will be removed without injuring the enamel. Rinse well afterwards with clean water. A much stronger dentifrice consists of the powder of burnt tobacco; but it contains silica, or gritty particles of sand, and cannot be recommended for common use. Indeed all preparations, such as those of chalk, pumice, cuttle-fish bone, &c. act mechanically, and are liable to the same objection. Chemical solutions are free from this objection; but unless their composition is thoroughly known, it is better to avoid them. In case of foulness or sponginess of the gums, powdered rhatany, cinchona bark, and catechu, on account of their astringent properties, have been found to be useful.

It is said to have been lately ascertained, by microscopic examination, that the *tartar* or *crust upon teeth* is produced in the same manner as coral, by certain animalcules. After the tartar, which is a mere nidus, adheres firmly to the teeth, the animalcules, by insinuating themselves between the teeth and the gum, occasion disease to both; but the secretion from them is often so offensive, as to contaminate the breath. M. La Beume has made numerous experiments with different mineral, vegetable, and animal acids, and with alcohol, to ascertain their effects on the animalcules, and on their habitation; and it is a curious fact, that of all the articles he has employed, the true *vinegar* acid (not the pyroigneous acid, which is now generally sold for it) almost instantaneously killed the animalcules, and acted powerfully to decompose the concretions, so that they were easily removed by a brush. In order to destroy the animalcules and their eggs, and to decompose the production which protects them, M. La Beume recommends the teeth to be brushed every morning with the vinegar acid diluted with rose-water, and immediately af-

terwards to make use of the powdered areca-nut charcoal, and the tincture of rhatany. The use of the diluted acetic acid every morning will, in the course of a few days, entirely remove the tartar, and the regular employment of the areca charcoal and tincture of rhatany every, or every other, morning, will effectually prevent the generation of the animalcules; but if there be a strong disposition to their production, he advises the diluted acetic acid to be used once a week. Dentists in general oppose the use of an acid, on the supposition that it is capable of decomposing the enamel. 'This opposition,' observes Dr Good, 'arises from an ignorance of the gradations of chemical affinities;' all of them, however, very freely use the most potent mineral acids to facilitate the removal of the tartar in the operation termed scaling. The true vinegar acid is incapable of acting chemically on the enamel of the teeth. We have made trial of the vinegar acid, which may be had of any chemist, and found it to be as effectual as above stated. Instead of areca-nut charcoal, we use the common refined wood charcoal, which seems to have the same effect. A lavation of this kind should not be performed oftener than twice a week, the tooth-brush and plain tepid water being used all other times.

*The Breath.*—Few things are more disagreeable or offensive than a fetid breath. 'Various means,' says the author of the 'Encyclopædia of Practical Receipts,' 'have been proposed to remove this annoyance, depending principally on the administration of aromatics, which, by their odour, might smother it for a time; but these require continual repetition, and are liable to interfere with the functions of digestion. The real cause of a fetid breath is either a diseased stomach or carious teeth. When the former is the case, aperients should be administered, and if these do not succeed, an emetic may be given, followed by a dose of salts or castor-oil occasionally. When rotten teeth are the cause, they should be removed; or, if this be impossible, they should be kept clean. Foul teeth often cause the breath to smell; and for this the use of the brush should be a daily habit. Occasionally rinsing out the mouth with a little clean water, to which a few drops of chloride of lime, or chloride of soda, has been added, is an effective method. The following lozenges have also been recommended:—Gum catechu, two ounces; white sugar, four ounces; orris powder, one ounce; make them into a paste with mucilage, and add a drop or two of neroli. One or two may be sucked at pleasure.' This, it must be observed, only disguises, not remedies the evil. A useful wash for carious teeth is made thus:—Chloride of lime, half an ounce; water, two ounces; agitate well together in a phial for half an hour; filter and add spirit, two ounces; rose or orange-flower water, one ounce. Use diluted, with water. Another very valuable wash for the teeth and gums, consisting of borax and tincture of myrrh and camphor, is thus prepared:—Dissolve two ounces of borax in three pints of warm water; before quite cold, add thereto one teaspoonful of tincture of myrrh, and one tablespoonful of spirits of camphor; bottle the mixture for use. One wine glass of the solution, added to half a pint of tepid water, is sufficient for each application.

*The Nails.*—Keeping the nails of the fingers in order is a proper duty of the toilet. They should be brushed with soap and water when washing the hands. While still wet, or when wiping the hands with the towel, push back the skin which is apt to grow over the nail, and thus keep the top of the nails neatly rounded. The points of the nails should be regularly pared once a week. For *whitening* the nails, we have seen the following mixture recommended:—Two drachms of diluted sulphuric acid; one drachm tincture of myrrh; and four ounces of pure soft water. The nails to be dipped into this mixture after the hands have been thoroughly cleansed with soap and water. Without adverting to the danger of such preparations, it may be remarked that the nails have naturally a delicate flesh or pinkish colour and shining polish, and that to

whiten them is as absurd as to stain them yellow after the fashion of the Orientals.

**The Hair.**—In a sound and healthy constitution, the best preserver and beautifier of the hair is regular and careful cleaning. Washing, combing, and brushing are quite sufficient to keep it in proper order; and where these fail, no amount of oils, lotions, powders, or appliances, will remedy the evil.—'Baldness,' says the authority above quoted, 'is generally produced by fever or old age, but is sometimes found in comparatively young people enjoying perfect health. When the hair-bulbs have disappeared, there is no means known that will restore the hair, notwithstanding the daily assurances to the contrary by numerous advertising impostors. When a disposition to baldness exists, or when the hair falls off in large quantities, the constant use of the hair-brush, and any emollient oil or pomatum, scented with some stimulating aromatic, will generally prove sufficient. Should this not succeed, the head should be shaved.'—*Stray hairs* sometimes grow in the nose and ears to an uncomfortable extent. Thin or shorten them with a toilet-scissors; or if it is wished to remove them—which is not always a very safe plan—do so smartly with a pair of tweezers. The chemical *depilatories* in use in the fashionable world are almost without exception highly objectionable preparations, having the effect not only of removing the hair, but destroying likewise the vitality of the skin to which they may be incautiously applied. The majority of them are composed of quicklime, orpiment, and some strong alkali—substances the name of which may warn parties against their application.—*Hair-dyes* are equally objectionable, and are all only temporary expedients, as the hair, upon growing, soon leaves an undyed surface beneath. They are principally of two sorts—those into which litharge and quicklime enter, and those in which nitrate of silver forms the chief ingredient. Thus to render the hair instantaneously black we are directed 'to moisten it with a solution of nitrate of silver in water (1 to 7 or 8), and then with a weak solution of hydrosulphuret of ammonia.'

**Pomatum.**—This is a soft unguent which is valuable for softening the hands, and preventing them chapping in cold dry weather, or for moistening the hair. It was originally named from its containing apple (*pomum*, Latin), and consisted of lard, rose-water, and the pulp of apples. It now consists of perfumed hogs'-lard, the apple being omitted. The famed *sultana pomatum* is made as follows:—Melt together half a pound of beef suet, the same of bears' grease, an ounce of white wax, and two ounces of olive-oil; and add to it, tied up loosely in muslin, one ounce of bruised cloves, half an ounce of cinnamon, two bruised tonquin beans, and four grains of musk; strain, and put into pots. The article called bears' grease, usually sold in the shops, is little else than perfumed beef-marrow; and the many oils offered for restoring and softening the hair are chiefly olive or almond-oil, perfumed with different scents. In general, if the hair be well brushed, no such applications are necessary, and in most cases they create a scurf on the head, which it requires considerable trouble to get rid of.

**Pomade Divine.**—This is a soft and valuable unguent, possessing a fine aromatic odour. Dr Biddoes recommends it to be made as follows:—Steep twelve ounces of beef-marrow in water ten days (changing the water occasionally), and then steep it in rose-water. Put it into a jar with half an ounce of flowers of benjamin, the same of storax and orris-root in powder, and two drachms each of cinnamon, nutmeg, and cloves, in powder. Cover the jar closely, set it in a vessel of water, and put it on the fire; and when the pomade is thus melted, strain it for use. As a very small quantity is ever used at a time, in general it will be found much more economical to buy a small bottle of it than to prepare the article.

**Cold Cream.**—This is a simple and cooling ointment, exceedingly serviceable for rough or chapped hands in winter, or for keeping the skin soft. It is very easily made. Take half an ounce of white wax, and put it

into a small basin, with two ounces of almond-oil. Place the basin by the side of the fire till the wax is dissolved in the oil. When quite melted, add two ounces of rose-water. This must be done very slowly, little by little; and as you pour it in, beat the mixture smartly with a fork to make the water incorporate. When all is incorporated, the cold cream is complete, and you may pour it into jars for future use. This cold cream is much better than that which is usually sold in shops, and which is too frequently made of inferior ingredients.—*Bears'-Grease*, which possesses no virtue or superiority over other animal fat, has rather an unpleasant odour, and is always sold (when sold at all) disguised with perfumes. A factitious article may be prepared as follows:—Hogs'-lard, sixteen ounces; flowers of benzoin and palm-oil, of each one-half ounce. Melt together until combined, and stir till cold. This mixture is said to keep long without becoming rancid, and may be scented at pleasure.

**A very fragrant Lavender-Water** may be prepared by mixing two ounces of English oil of lavender, one ounce of essence of ambergris, one pint of *Eau de Cologne*, and one quart of rectified spirit.

**Spermaceti Ointment.**—This is a cooling and healing ointment for wounds. Take a quarter of an ounce of white wax, and half an ounce of spermaceti (which is a hard white material), and put them in a small basin with two ounces of almond-oil. Place the basin by the side of the fire till the wax and spermaceti are dissolved. When cold, the ointment is ready for use. This is an article which it is also much better to make than to purchase. When you make it yourself, you know that it has no irritating or inferior materials in it.

**The Feet—Corns.**—To keep the feet in a proper condition, they should be frequently soaked and well washed. At these times, the nails of the toes should be pared, and prevented from growing into the flesh. Corns are the most troublesome evils connected with the feet. They are of two kinds—soft and hard. Soft corns are those which grow between the toes. They may be easily removed by applying ivy leaf steeped in vinegar; if the corn be very painful, change the piece of ivy leaf every morning. The leaf may be steeped for one or two days before using. Hard corns, which grow on the outside of the toes, are caused by friction from the shoes; and we know of nothing so likely to prevent them as easy soft shoes and very frequent soaking of the feet in warm water. Every method of extracting corns seems but to afford temporary relief, and never will be attended with complete success unless attention is paid to the shoes. It is very dangerous to cut corns too deep, on account of the multiplicity of nerves running in every direction of the toes. Caustic, or strong acids, have the desired effect in removing corns, but their use should be committed to the hands of a skilful surgeon.—The *bunion*, or swelling on the ball of the great toe, is produced by the same cause as the corn—pressure and irritation by friction. The treatment recommended for corns will succeed in cases of bunions; but in consequence of the greater extension of the disease, the cure of course is more tedious. When a bunion is commencing, it may be effectually stopped by poulticing, and then opening with a lancet; but this must be committed to the hands of a surgical attendant.—For *chilblains*, Sir A. Cooper has recommended the following liniment:—One ounce of camphorated spirits of wine, half an ounce of liquid subacetate of lead; mix, and apply in the usual way three or four times a day.

**Cosmetics.**—These consist of washes and pastes for improving the skin, and are in general highly objectionable; for the greater number contain poisonous ingredients, and while removing from the surface any discoloration, drive the disease inward, and therefore do much more harm than good. Lotions for pimples, freckle-washes, milk of roses, rouge, and all such trash, we studiously discommend. The best of all purifiers is water with a cloth; the best beautifiers are *health, exercise, and good temper.*

## INDEX, AND GLOSSARY OF TERMS.

\*\* The Figures in the columns indicate the pages of the Text in which the particular term or subject is fully explained.

**ABATEMENT**, in heraldry, symbols of disgrace introduced into arms, as in the case of bastardy, cowardice, and the like; in law, a plea of abatement is pleaded to a declaration, writ, and so forth, on account of some defect in form.

**Abbreviation** (Lat. *brevis*, short), a term applied to certain processes of abridgment in arithmetic; in music, a stroke which, placed over or under a note, divides it into quavers, if there be only one—if two, into semiquavers—and if three, into demisemiquavers; in writing, the use of contractions or initials for entire words. Before the invention of printing such abbreviations were exceedingly frequent, now they are employed chiefly in titles, thus:—

- A. B. or B. A., Bachelor of Arts.
- A. D. (*Anno Domini*), in the year of our Lord; A. H., in the year of the Hejira; A. M. (*Anno Mundi*), in the year of the world; A. C. or B. C., the year before Christ; A. U. C. (*Anno Urbe Condita*), the year from the building of Rome.
- A. M. or M. A., Master of Arts.
- A. M. (*Ante Meridian*), forenoon; P. M. (*Post Meridian*), afternoon.
- B. C. L., Bachelor of Civil Law.
- B. D., Bachelor of Divinity.
- C. B., Companion of the Bath.
- C. E., Civil Engineer.
- Clk., Clerk.
- D. C. L., Doctor of Civil Law.
- D. D., Doctor of Divinity.
- D. G. (*Dei Gratia*), by the grace of God.
- E. I. C., East India Company; E. I. C. S., East India Company's Service.
- F. D., Defender of the Faith.
- F. R. S., Fellow of the Royal Society; L., of London; E., of Edinburgh.
- G. C. B., Grand Cross of the Bath.

**Aberdeen**, description and account of, 239.

**Abridgment**, in literature, a compendious arrangement of the matter contained in a larger work; differing from an abstract, which gives a mere analysis or general view of the leading particulars. The French word *précis* is sometimes used as synonymous with

abstract; so also synopsis, which is a Greek word, signifying a collective view of any subject, as a synopsis of geology, astronomy, and the like.

**Abstractions**, in Logic, 361.

**Academia**, a pleasant and finely-wooded spot in the vicinity of Athens, which derived its name from the proprietor Academus, and became renowned as the spot where Plato taught philosophy to his pupils. These were thence termed Academics; and a familiar appellation (*Academy*), originating in the same source, is bestowed on seats of learning and education at the present day.

**Accolade** (Lat. *ad*, to, and *collum*, the neck), the touch or slight blow given to the neck or shoulder on dubbing a knight.

**Accordion**, musical instrument, 768.

**Achaia**, a district of the Peloponnesus or Morea, the people of which held so considerable a station among the ancient Greeks, that their name was frequently used to denote the entire population of the country.

**Achates**, a follower of Æneas, so faithful and devoted, that his name has become proverbially significant of constancy in friendship.

**Acheron**, a gloomy river in the fabulous infernal regions of the classical mythology.

**Achilles**, son of Peleus, king of Thessaly, by the sea-goddess Thetis. Educated by Chiron, a learned centaur (half man, half horse), Achilles is represented as having become perfect in all the accomplishments of his heroic age, and had just attained the prime of youthful manhood, when the princes of Greece went to war with Troy. Thetis, foreknowing that her son would fall in that contest, disguised him as a female to prevent his entering into it; but he was detected, and, not against his will, went with the other chiefs to Troy, where he distinguished himself above all the Greeks by consummate daring and prowess. A quarrel with the leader, Agamemnon, caused him at length to withdraw in disgust from the field; and in spite of the intreaties of his countrymen, he remained obstinately inactive in his ships, until the death of Patroclus by the hand of Hector caused him to don the splendid panoply formed for him by the armourer of the gods, and rush to the scene of battle. Many Trojans fell before the infuriated chieftain, and, finally, Hector himself was cast lifeless on the field. In his youthful days Thetis had rendered her son invulnerable by dipping him in the river Styx; but the tendon of the heel by which she held him (hence called the *tendo Achillis*) was left unsecured, and Paris, the brother of Hector, slew the chief by a wound in that spot, thus fulfilling the decree of fate. Strength, swiftness, and beauty of person, are the leading characteristics assigned to Achilles by Homer.

**Acquisitiveness**, in Phrenology, 342.

**Acrocorinthus**, the citadel rock of Corinth, an eminence of great height and strength.

**Actæon**, a Boeotian huntsman, who, having accidentally beheld Diana bathing, was changed by the chaste goddess into a stag, and torn to pieces by his own dogs. The 'fate of Actæon' is a phrase expressive of the ruin of a man by his own friends, or from unwittingly becoming cognisant of dangerous secrets.

**Activities**, of the Human Mind, 334.

**Adagio** (Ital. leisurely), in music, the slowest of musical tone, grave only excepted.

Addition, in Arithmetic, 595; in Algebra, 604.  
 Address, forms of, in Rhetoric, 693.  
 Adhesiveness, in Phrenology, 340.  
 Adjectives, in Grammar, 578; inflection of, 582.  
 Administration of government, 45.  
 Adonis, a youth of great beauty beloved by Venus, who, on his being gored to death by a wild boar, converted him into the flower anemone.  
 Adverb, in Grammar, 579.  
 Æneas, a Trojan prince, son of Anchises and Venus, who, on the fall of Troy, is said to have wandered with a small band to Italy, and to have there laid the foundation of the Roman Empire. The Romans were proud of this traditional descent; and Virgil made it the subject of his great national epic, 97.  
 Æolian harp (so called from Æolus, god of the winds), a simple instrument which produces a pleasing combination of sounds by the action of the wind. It consists of strings of catgut, or wire, stretched parallel over a thin box of deal, with sounding holes cut in the top. The strings being tuned in unison, the effect is produced by placing the instrument in a current of air, such as is caused by opening a door or window.  
 Æolus, the god of the winds, according to the classical mythology. The 'Æolian harp' derives from him its designation.  
 Ærarians, the artisan class of ancient Rome, 101.  
 Æschylus, a tragic writer of Athens, whose style is peculiarly vehement and sublime.  
 Æsculapius, a personage honoured as the god of medicine, and reputed to be the son of Apollo by a mortal nymph. Exposed in infancy, to save his mother's reputation, he fell under the care of Chiron the centaur, and acquired such skill in the healing art as even to recover dead persons from the grave. For this feat, Pluto, the king of the nether realms, persuaded Jupiter to kill him with a thunderbolt. Many temples were erected to Æsculapius; and he was generally represented in the form of an old man, with one hand on a staff and the other on a serpent's head. The latter animal is to this day the emblem of medical science; and the name of the supposed divinity is often familiarly applied to the art and its professors.  
 Æsop, a native of Phrygia, renowned as a writer of fables. His actual productions are lost; but the Latin fabulists profess to have translated from his original Greek. He is stated to have been deformed in person, and a slave by station.  
 Æsthetics (Gr. *aisthētikos*, having the power of perception by means of the senses): in the fine arts that science which derives the first principles in all the arts from the effect which certain combinations have on the mind, as connected with nature and right reason.  
 Ætna, the most famous volcanic mountain in the world, situated in Sicily, and rising to a height of 10,870 feet above the sea-level. The noise and flame emitted from it led the imaginative ancients to make its interior the workshop of the smith-god Vulcan, 198, *et passim*.  
 AFRICA, GENERAL DESCRIPTION AND ACCOUNT OF, 273-280.  
 Agamemnon, king of Mycenæ, in the Peloponnesus, and leader of the Greeks in the expedition against Troy. The character given to him by Homer is one of massive grandeur. He was murdered, on his return home, by his wife Clytemnestra and her paramour Ægisthus.  
 Aglaia, one of the three Graces, 87.  
 Agrarian Law, in Roman history, 99.  
 Agricola (Cn. Julius), a Roman general, who, under various emperors, served with great distinction in Britain.  
 Agricultural statistics of Britain, 185.  
 Aide-de-camp (Fr.), an officer appointed to attend a general officer in the field, in winter quarters and in garrison, to receive and carry orders.

Air (ventilation), duties regarding, 451.  
 Ajax, son of Telamon, and famous in the war of Troy for his bravery and vast though unwieldy strength. He became mad, and slew himself, because the arms of the deceased Achilles were not assigned to him.  
 Alarms in churches and theatres, 776.  
 Album, originally a white board or tablet on which the prator's edicts were written; the modern application of the term is sufficiently familiar.  
 Alcestis, wife of Admetus, king of Phæra, who voluntarily died for her husband's sake, and was brought again from the regions of the dead by Hercules.  
 Alcibiades, an Athenian noble, remarkable for beauty of person and intellectual capacity, and not less notorious for his vices and luxurious effeminacy. He was a pupil of the philosopher Socrates, and owed much to his instructions. After a youth spent for the most in folly, yet fully redeemed in part by generous actions, he entered into the service of the state, and showed eminent talents as a military and naval commander, 93-94.  
 Alecto, one of the three Furies, daughters of Nox or Night, 87.  
 Alexander, a name borne by several Macedonian princes and others, but rendered chiefly illustrious as the designation of the son of Philip of Macedon by his wife Olympias; his career, 95-96.  
 Alexandria, a city of Egypt, founded by Alexander the Great, famous for its lighthouse, its learned men, and its two splendid libraries, successively destroyed by Augustus Cæsar and the Caliph Omar.  
 Alexandrine, in versification the French heroic verse of twelve syllables or six iambic feet; *e. g.*—  
 'Which, like a wounded snake, drags its slow length along.'  
 Algebra, 604-608; logic of, 366.  
 Alimentiveness, in Phrenology, 341.  
 Alliteration, in rhetoric, the consecutive use of words beginning with or containing the same letter, as—  
 'And round the rugged rocks the ragged ruffian ran.'  
 Amalthea, the reputed nurse of the god Jupiter, whom she fed with goat's milk. Some mythologists say that she herself was a goat, and her horn is often termed the 'Horn of Plenty.'  
 Amativeness, in Phrenology, 340.  
 Amazon.—The Amazons are said to have been a tribe of Scythian women, who did not allow men to live with them, killed the majority of their male children, and trained their female offspring to war, burning off their right breasts for the better use of the bow. Whether an imaginary race or not, the word Amazon has become a proverbial designation for a woman of masculine habits and temperament.  
 Ambassadors, functions of, in diplomacy, 45.  
 Ambition, metaphysically considered, 534.  
 AMERICA, NORTH, GENERAL ACCOUNT OF, 289-304; SOUTH, 305-320; BRITISH, 292.  
 American war of independence, 162.  
 American antiquities, 687.  
 American variety of mankind, physical and mental characteristics of, 5.  
 Ammon.—In mythology, a Libyan divinity, adopted by the Greeks, and by them identified with their Jupiter. An oasis in the deserts bordering on the Nile contained a famous temple and oracle of Jupiter Ammon, the ruins of which are still discernible.  
 Amphictyon, a person who founded a general council for the twelve leading states of Greece, and from whom such assemblages were permanently called Amphictyonic Councils, 89.  
 Amphion, an individual of semi-divine origin, who founded Thebes, in whole or part, and is stated to have excelled so much in music as to have moved the stones voluntarily to take their places in the structures of the new city.  
 Amphitryon, husband of Alcmena, the mother of Hercules by Jupiter. An expression of Molière in a play on this subject, 'L'Amphitryon où l'on dine,' has

## INDEX, AND GLOSSARY OF TERMS.

- caused a hospitable dinner-giver to get the familiar name of an Amphitryon.
- AMUSEMENTS, IN-DOOR, 657-672.**
- Amusements and Recreations, duties regarding, 477.
- Anacreon, a bard of Iona, whose graceful verse is devoted to love and wine.
- Analogy (Gr.) in ordinary language signifies a relation or similarity between different things in certain respects. It is used as a term, with slight differences of meaning, in logic, rhetoric, and mathematics.
- Andromaché, wife of Hector and mother of Astyanax, celebrated by Homer for her conjugal affection and domestic virtues.
- Androméda, daughter of an Ethiopian king, who, being chained to a rock, and exposed to a sea-monster, was rescued from that peril by Perseus, son of Danae, and, by promise, became his wife.
- Anger, regulation of, 458.
- Angles, in Geometry, 611.
- Anglo-Saxon, Superstitions, 419.
- Animal Physiology, design in, 373.
- Animated Nature, compensation of parts in, 379.
- Annuities, in Social Economics, 539.
- Antæus, son of the earth and sea, a Libyan giant, slain by Hercules. When a man seems to derive fresh vigour from an overthrow, he is compared to Antæus, because, at every fall, his mother earth gave that giant fresh strength; and Hercules only foiled him by holding him up, and squeezing him to death.
- Anthologies (Gr. *anthos*, blossom, and *logos*, discourse). The Greek anthologies are collections of minor poems, chiefly epigrams, of various authors. Many of the pieces are remarkable for their beauty and simplicity in thought, and their peculiar turns of expression. The term is now applied more generally to any collection of minor pieces.
- Antinöus, a friend of Adrian, whose form, as represented by ancient sculptors, has become significant of a peculiar description of physical beauty.
- Antiquities—see Archæology, 673-688.
- Antonius (Marcus), a Roman, who shared for a time the empire of the world with Augustus Cæsar, 110.
- Anúbis, an Egyptian idol, represented with the head of a dog.
- Apelles, a native of the isle of Cos, usually regarded as the greatest of the ancient painters. He followed for a time the fortunes of Alexander.
- Aphorism (Gr.), a comprehensive maxim or principle expressed in a few words.
- Apicius, a noted Roman epicure, who expended £800,000 on his appetite, and finally killed himself in fear of want, the £80,000 which still remained to him at the time being insufficient to sustain the proper rate of gourmandising extravagance.
- Apis, a god of the Egyptians, venerated under the form of a white bull.
- Apocrypha, history of the, 390.
- Apollo, the son of Jupiter and Latona, god of the sun, music, medicine, and the fine arts. Born in the isle of Delos, he soon after slew the serpent Python, sent by Jupiter's wife to plague Latona, and thus gained for himself the name of the Pythian Archer. A noble ancient statue, existing in Rome, and splendidly described by Lord Byron, gives an image of him in this character. He is usually pictured as a beardless youth, holding a bow or lyre. Like others of the mythological deities, he is said to have had many amours with the daughters of earth, and even to have dwelt there for nine years as a shepherd when expelled from heaven by his sire. The chief supplementary names given to him in poetry are—the Delian, Cynthian, Delphic, and Lycian god; and, as sun-god, he is commonly named Phoebus. His principal temples and oracles were at Delphi, Delos, and Claros, the Delphic one being the most renowned oracle of the earth. A youth of fine form is often styled an Apollo, and the poets allude endlessly to the god as their patron and guardian.
- Appetites, metaphysically considered, 327.
- Applegath's printing-machines, 717-720.
- Appraiser, one who values goods under distress for rent; Appraisement, the value of goods sold under such valuation.
- Approbation, love of, in Phrenology, 543.
- April festival, Calendar for, 439.
- Aquatinto, species of engraving, 727.
- Arabesque (Fr.): painting and sculpture after the Arabian taste, which largely employed a capricious and fantastic but highly-imaginative species of ornament composed of fruits, flowers, and other objects.
- Arabia, ancient history of, 73.
- Arachné, a woman of Colophon, so well skilled in needlework that she challenged competition with Minerva, and, being defeated, hanged herself, on which the goddess changed her to a spider.
- Arcadia, a pastoral region in the centre of the Peloponnesus, so much distinguished for natural beauty, and for the happy and simple life of its population, that the word has long been used to signify a scene of rural and inartificial enjoyment.
- ARCHÆOLOGY**, science of, 673-688.
- Archimedes, a geometriician of Syracuse, of great abilities. Among his other inventions, he is said to have discovered a mode of setting fire to ships from a distance by means of burning-glass—a feat which Buffon proved to be not practicable. When his sovereign suspected a tradesman of having used some alloy in making a golden crown, Archimedes was applied to in order to discover the truth. At a loss at first, the philosopher finally ran out of his house towards the palace, crying, '*Eureka!*' ('I have found it!')—the idea having occurred to him of immersing the crown in a vessel of water, and measuring what quantity of liquid ran over. He was killed at the siege of Syracuse; and though interred with honour, the spot where he lay remained long unknown, till discovered by Cicero. Archimedes also invented the pumping-screw. A small part only of his writings is now in existence.
- Archipelägus (Archipelago), a name given to any sea studded with islands, as the Grecian or Indian Archipelago.
- Archives, a term signifying properly the repositories of public documents and records, but often applied to the records themselves.
- Archons, the ancient title of the chief magistrates of Athens, 85.
- Areopagitæ, the judges of the Areopagus, a seat of justice on a mount near Athens.
- Arèthusa, a nymph of Diana's train, changed by her mistress into a Sicilian fount, to preserve her from the pursuit of the Grecian river-god Alpheus.
- Argent (Lat. *argentum*, silver), a term in Heraldry, 47.
- Argo, a famous ship of antiquity, which is said to have carried Jason and a renowned body of Greeks (called the Argonauts) to Colchis, a district on the eastern shore of the Black Sea, in quest of a Golden Fleece, surreptitiously taken from the Greeks. Numerous writers have treated of this subject.
- Argus, a being with a hundred eyes, set by Juno to watch an earthly mistress of Jupiter, and slain by Mercury. A jealous custodian often receives the title of an Argus.
- Ariadné, daughter of Minos, king of Crete, who, when the Athenian prince Theseus was shut up in the celebrated Cretan labyrinth to be devoured by a monster, gave him a clue of thread by which he extricated himself. The Clue of Ariadné has become a byword. Being cruelly abandoned by Theseus, Ariadné, according to the poets, gained the love of the god Bacchus, and by him was elevated to a place among the constellations.
- Arian, or Indo-European race, in Ethnology, comprehends the Hindoos, Persians, Affghans, Armenians, and the great bulk of the European nations, 1.
- Arion, a famous musician, who, when in peril of his

## CHAMBERS'S INFORMATION FOR THE PEOPLE.

- life at sea, played so sweetly that some grateful dolphins bore him safely ashore.
- Aristides**, a statesman and warrior of Athens, whose conduct earned for him the title of the *Just*, 91.
- Aristocracies and aristocratic governments**, 41.
- Aristophanes**, a famous comic satirist of Athens.
- Aristotle**, a Greek philosopher of the first rank, born at Stagyræ in Macedonia, and hence called the Stagyræite. After studying under Plato, who valued him so much as to style him the *mind* of the school, Aristotle opened a seminary of his own, and long taught with great success. From his lecturing to his pupils while walking, they received the name of the Peripatetics. Aristotle also spent ten years as the tutor of Alexander the Great, who said that 'Philip had given him life, but Aristotle had taught him to live well.' By the aid of this prince, the philosopher was enabled to produce his 'History of Animated Nature,' describing from collected specimens. He also wrote on physics, metaphysics, ethics, logic, rhetoric, and criticism. His canons on the latter subject are yet held in high respect. Compelled to leave Athens, Aristotle died at Chalcis, at the age of sixty-five.
- ARITHMETIC**, 593-604; mental, 601; logic of, 365.
- Armada**, the Spanish, 138.
- Arms**, or Armorial Bearings, in Heraldry, 46.
- Army and navy of Britain**, 184.
- Arria**, wife of the Roman Poetus, famous for stabbing herself, and saying, 'Oh, Poetus, it is not painful!' when her husband hesitated to free himself in the same manner from his woes.
- Arúspices**, Roman soothsayers, who pretended to foretell events by the inspection of the entrails of the animals sacrificed at the altars.
- Ascanius**, son of the Trojan Æneas, and successor to his power in Italy. The young inheritor and hope of a house or party is sometimes designated by this title.
- Ash-Wednesday**, festival of, 435.
- ASIA**, general description and account of, 257-260.
- Asia-Minor**, ancient states of, 79.
- Aspasia**, a celebrated courtesan of Athens, mistress and ultimately wife of Pericles, and so eminent for her intellectual accomplishments that even modest women resorted to her to enjoy her instructive converse, 92.
- Assertions and propositions**, in Logic, 356.
- Association**, law of, in metaphysics, 330; in Phrenology, 352.
- ASSURANCE-LIFE**, 524-528.
- Assyrians**, the ancient, 77; antiquities, 676.
- Astræa**, the goddess of Justice in the classical mythology, 87.
- Astronomy**, logic of the science, 367.
- Atalanta**, a princess of the isle of Scyro, of great beauty, and determinedly averse to matrimony. As she excelled in running, she consented to wed him who foiled her in a trial of speed, and defeated all her lovers, until one came forward who was favoured by the goddess of Love. From that deity he received three golden apples, and was directed to throw them down at intervals in the race. The stratagem succeeded. Atalanta could not refrain from stopping to pick up the apples, and the lover obtained her hand. But for subsequent disrespect to Jupiter, the pair were changed into a lion and lioness. The race of Atalanta is often alluded to.
- Athens**, history of, 90, 94.
- Athos**, a mountain of Macedonia, which a sculptor proposed to cut into a vast statue of Alexander the Great.
- Atlas**, a Titan or giant who warred with Jupiter, and was ultimately changed into the mountain, or chain of mountains, of the same name in Africa, which, from their height, were supposed to support the heavens. Hence the frequent allusions to the load of Atlas, 274.
- Atmospheric illusions**, 430.
- Atreus**, king of Argos, who, having cause of offence against his brother Thyestes, caused the latter unwittingly to eat the flesh of his own children. The son of Thyestes revenged this deed by slaying Agamemnon, the son of Atreus.
- Atropos**, one of the Fates, or Parœe, whose task it was to cut the thread of life.
- Attachés** (Fr.), a term applied to certain unofficial parties connected with or attached to an embassy; see diplomacy, 45.
- Attica**, a district of Greece, lying south of Boeotia, and west of the Ægean Sea. It was supposed to be so peculiarly favourable to genius, and its dialect to be so pure, that the phrase of 'Attic wit' or 'salt' became indicative of the highest literary merit, as garrets got the name of 'Attics' from writers being too often the inhabitants of such poor places in times not far distant.
- Atticus**, an intimate friend of the orator Cicero, and a man pre-eminently distinguished by the superior qualities of his head and heart.
- Augeas**, king of Elis, whose vast stables for oxen and goats were so overrun with filth, that it was deemed impossible to cleanse them, until Hercules effected the task by turning a river into them. Difficult cases of purification or reformation are proverbially compared to this Herculean feat of cleaning the Augean stables, 82.
- Augurs**, Roman soothsayers, who pretended to foretell events by the flying, singing, and feeding of birds.
- August**, festival Calendar for, 443.
- Aurora**, the goddess of the Morning, usually represented as drawn by two horses in a rose-coloured chariot. She was called sister to the sun and moon, and mother of the winds and stars.
- Australasia**, description and account of, 282-288.
- Australia**, colonies of, 284.
- Austria**, description of, 201.
- Autograph** (Gr. *autos*, self, and *grapho*, I write), a piece of writing in one's own hand.
- Avarice**, as a mental desire, 334.
- Aventinus**, one of the seven hills on which Rome was built; Aventine mount.
- Avernus**, a lake of Campania, so unwholesome and putrid that the ancients made it the entrance of the infernal regions.
- Babel**, Babylon, in Ancient History, 76.
- Babylonians**, the ancient, 77; Babylon, 78.
- Bacchantes**, priestesses of Bacchus, who did honour to the god of wine by the most frantic and licentious orgies, 86.
- Bacchus**, god of wine, son of Jupiter by Semele, who, being a mortal, fell a victim to her vain wish of seeing her lover in all the blaze of his divinity. Jupiter rescued her unborn child from the same fate, and placed him in his own thigh until grown to infant maturity. Bacchus, in his adult state, underwent many adventures, according to the poets. He made an expedition to India with his Bacchanalian followers, and made an easy conquest of the intermediate nations, teaching them the use of the vine. As Bacchus the conqueror, he is painted as drawn in a chariot by a lion and a tiger; and in other circumstances he is represented as a plump, smooth-skinned young man, with a crown of vine and ivy leaves, and a thyrsus or rod in his hand. His common names, besides that mentioned, are Iacchus, Liber, Bromius, Lyæus, and Evan. The rites in his honour were called Bacchanalia, 86.
- Backgammon**, game of, 662.
- Baconian Philosophy**—the Inductive Method propounded by Francis Bacon, Lord Verulam.
- Bagatelle**, game of, 666.
- Bahamas**, or Lucayos Islands, West Indies, 318.
- Ball**, games with, 656.
- Ballet** (Fr.), in theatricals, a representation of actions, characters, sentiments, and passions, by means of mimic movements and dances, accompanied by music.

## INDEX, AND GLOSSARY OF TERMS.

- Banco** (Ital. a bench), in commerce, a bank, but commonly applied to the Bank of Venice; in law, the superior courts of common law are said to sit *in banco* during term.
- Bankruptcy or insolvency**, law of, 502.
- BANKS**, origin of, 507; business of, 507; Bank of England, 508; joint-stock banks, 509; Scotch, 510; Irish, 512; savings', 512.
- Barbadoes**, island of, 317.
- Barclay**, Captain, his pedestrian feats, 645-647.
- Baron and baronet**, ranks of, 48.
- Barrows**, in Archeology, 679.
- Base or base**, in Music, 738.
- Bassoon**, musical instrument, 766.
- Bathos** (Gr. *bathos*, depth), in rhetoric, a term applied to a ludicrous descent from elevated to mean.
- Bavius and Mavius**, two inferior and malevolent poets in the time of Augustus Cæsar, whose names have become a by-word for all envy of superior merit.
- Beards' grease**, how to make, 784.
- Beauty**, emotion of, in metaphysics, 335.
- Beauty**, theological considerations respecting, 380.
- Belfast**, description and account of, 254.
- Belgium**, description of, 204.
- Beliefs**, metaphysically considered, 335.
- Belisarius**, an able general of the Constantinopolitan emperor, Justinian, reduced to beggary in his old age, and afflicted with blindness. '*Dote obolum Belisario*'—('Give the smallest coin to Belisarius'), the usual petition of the fallen soldier, has become proverbial.
- Belize or Honduras**, British settlement of, 297.
- Bellerophon**, a son of the king of Ephyre, who, having committed an act of violence, fled to the court of Prætus, king of Argos, where the queen fell in love with him, and finding herself alighted, accused him to her husband. The latter sent Bellerophon to Lycia with sealed letters, desiring that the bearer should be put to death. The Lycian king sent his guest, with this view, against a monster called the Chimæra, but receiving from Minerva a winged horse called Pegasus, Bellerophon overcame the monster; and after other trials, ultimately wedded the daughter of the Lycian monarch. From this story, all letters unfavourable to the bearer have been called '*Letters of Bellerophon*.'
- BELLES-LETTERS, or POLITE LITERATURE**, 689.
- Bellona**, sister and charioteer to Mars, the god of war.
- Benevolence**, sentiment of, in Phrenology, 344.
- Berenice**, a name borne by several Egyptian princesses, one of whom was noted for her beautiful hair, which was placed by her in the temple of Venus. Being lost, the locks were said by the court-astronomers to have been turned into a constellation.
- Bermudas or Somers' Islands**, 319.
- BIBLE, THE, HISTORY OF**, 385-394.
- Biblia Pauperum**, in history of printing, 705.
- Bibliography** (Gr. *biblion*, a book, and *grapho*, I write), literally the science of books. It is customary to speak of intellectual bibliography and material bibliography; the former implying the knowledge required to describe and arrange books according to the subjects of which they treat, and the latter a knowledge of the external peculiarities of books, their editions, &c.; but such a division is rather arbitrary than real, bibliography as a science comprehending all that appertains to the '*history of the book*,' from the earliest to the latest times.
- Bibliology** (Gr. *biblion*, a book, and *logos*, discourse), a description or account of books; used synonymously with bibliography; the science which treats of books.
- Bill of lading**. See commercial terms, 501.
- Billiards**, game of, 663.
- Bills of Exchange**, 505.
- Bills of mortality**. See Mortality.
- Birds**, design in the structure of, 375.
- Birmingham**, description and account of, 219.
- Births**, statistics of, 546.
- Bishop**, origin of the term and office, 396.
- Black letter**, the old English or modern Gothic letter, introduced into England about the end of the fourteenth century.
- Blacking**, for shoes, &c. how to make, 779.
- Bleaching**, in domestic economy, 779.
- Boadicæa** (or *Bondices*), queen of the Icenians, a tribe of South Britons, who took up arms to avenge the outrages of the Romans, but, in spite of her undaunted conduct in the field, was vanquished by them, and poisoned herself.
- Bœotia**, a district of Greece, now forming part of Livadia, and lying between Phocis and Attica. Partly from an idea that the atmosphere of the region was peculiarly thick, the inhabitants gained a reputation for stupidity, which has yet adhered to their name. Yet Pindar, Plutarch, and others of the brightest spirits of Greece, were Bœotians.
- Bolivia**, republic of, described, 309.
- Bombay**, description and account of, 271.
- Boodhism**, account of, 405.
- Boreas**, a title of the north wind.
- Borgha**, in Archeology, 679.
- Bosphorus**, the early name for the Strait of Constantinople.
- Bourgeois**, a variety of type, in Printing, 709.
- Bowls**, games with, 653.
- Brain**, the, phrenologically considered, 357.
- Brass and copper vessels**, how to clean, 772.
- Brazil**, empire of, described, 311.
- Breath**, fetid, how to remove, 783.
- Brevier**, a variety of type, in Printing, 709.
- Briareus**, a famous giant, with fifty heads and a hundred hands, son of the Heaven and Earth.
- Bristol**, description of, 220.
- BRITAIN, HISTORY OF**, 129-176; constitution of, 177-192; resources of, 177-192; conquest of by the Romans, 129; conquest of by the Saxons, 129; conquest of by the Normans, 130; government of, 177; laws, 179; religion, 180; education, 181; finances of, 183; army and navy, 184; agriculture, manufactures, and commerce of, 185; public works, &c. 188; colonial possessions, 189; population of, 191; social statistics of, 191.
- Britain, New**, in North America, 292.
- British constitution**, character of, 42.
- Broker**, a somewhat indefinite term in commerce and mercantile law for one who contracts for the sale or disposal of goods belonging to other parties. Thus there are bill-brokers, stockbrokers, insurance-brokers, shipbrokers, pawnbrokers, and brokers who sell or appraise household furniture for rent. Brokerage is the term applied to a broker's remuneration, or per-centage.
- Brutus** (Lucius Junius), a noble Roman, who, in the days of the last king of Rome, feigned himself an idiot to insure his safety, but threw off the mask, and overturned the royal authority, when Lucretia fell a victim to the brutality of the son of Tarquin. When the sons of Brutus afterwards conspired to restore the Tarquins, he himself, as consul, was called upon to act as judge, and his high-minded victory over parental feeling has made his name immortal.—Brutus (Marcus Junius), descendant of the preceding, who emulated his virtues and his fame. When the power of Julius Cæsar became dangerous to the liberties of Rome, Marcus Brutus, though one of his warmest personal friends, rose against him, and united with Cassius and others in stabbing him in the Capitol. Cæsar, as he received the last blow, uttered to him who dealt it the memorable words, '*Et tu Brute!*'—('Thou, too, Brutus!') The friends of Cæsar were avenged at Philippi, where the chief conspirators fell; and Plutarch tells that Brutus was forewarned of the event by the spirit of Cæsar, which appeared in his tent, and said, '*I will meet thee again at Philippi*'—words often used to convey an indication of coming evil.
- Bucéphalus**, a horse tamed by Alexander the Great in youth, and which became so renowned for bearing him in the field of battle, as to give a common name to all spirited animals of its species.

- Budget**, a *vidimus*, or statement of the income and expenditure of a nation; usually applied to the annual parliamentary statement of the Chancellor of the Exchequer.
- Bugs**, how to kill, 774.
- Bull**, papal (Lat. *bullæ*), an ordinance or decree of the pope, equivalent to a proclamation, edict, or order of any secular prince.
- Bunions**, how to remove, 784.
- Burning**, escapes from, 775.
- Cadences or Closes**, in Music, 760.
- Cadet** (Fr.), a pupil in a military academy, whose object is to qualify himself as an officer. The chief military institutions in this country are Sandhurst for the British line; Woolwich for the artillery and engineers; and Addiscombe for the Indian army, both line and artillery.
- Cadmus**, a prince of Phœnicia, who generally receives the credit of inventing letters, or at least of introducing them into Greece. Though some writers ascribe the erection of Thebes to Amphion's music, others term Cadmus its founder. Ere he could do so, he killed a dragon which had devoured his companions; and from the teeth of this monster, when sown in the earth, a band of armed men sprung up. These fought among themselves, till only five were left to assist Cadmus in building the city. The sowing of the teeth and its consequences are often alluded to, and form an apt comparison when the germs of strife are planted in any instance, 82.
- Caduceus**, a rod entwined at one end by serpents, and which served as the rod of power and office of the herald-god Mercury, 87.
- Cæsar**, an illustrious name in history, first given as a surname to the Julian family of Rome. Caius Julius Cæsar, who gained for the family supreme power, was born in the year 100 B. C., and early distinguished himself by his eloquence, his captivating manners, and generous habits of life, 108-110.—Cæsar (Octavius, afterwards named Augustus), nephew of Julius Cæsar, and his successor in power, 109-111. The title of Cæsar is specially given to the first twelve emperors (commencing with the dictator, Julius Cæsar) who sat on the Roman throne. It was also assumed by later Roman emperors; and both the *kaisars* of Germany and the *czars* of Russia owe their designation to the same source.
- Cairns**, in Archæology, 679.
- Calcutta**, description and account of, 271.
- CALENDAR**, KEY TO THE, 433-448.
- Caligula**, the fourth of the twelve Cæsars, who derived his name from his habitually wearing the *caligæ* or military boot of the age, and made himself noted as a cruel and senseless tyrant. From mere wantonness he made his horse high priest and consul of Rome; and he spilt blood without cause and without remorse. He died a violent death, 111.
- Calliopé**, one of the Muses, 87.
- Calotype** or Talbotype, art of, 734.
- Calvinists**, the followers of Calvin, the second great reformer of the sixteenth century, and founder of the church of Geneva, 400.
- Calypso**, a beautiful goddess, who, according to Homer, dwelt on an island of the earth, and who received Ulysses hospitably as he wandered home from Troy.
- Camera-obscura** for photography, 733.
- Camilla**, queen of the Volsci, who fought against Æneas, and is described as having been so swift of foot that she could fly over a field of corn without bending the blades.
- Campus Martius**, a plain near Rome, used for the military exercises of the youth of the city.
- Canada**, description and account of, 293.
- Candlemas-day**, origin of, 434.
- Canon**, in musical composition, 764.
- Cape Colony**, description and account of, 279.
- Capital**, in Political Economy, 496; in Commerce, 500.
- Capitolium**, the citadel of ancient Rome, founded on the Tarpeian Rock, and containing also a temple, from which Jupiter was named Capitolinus. The Capitol was a noble structure, occupying four acres of ground, and accessible by a hundred steps. The Romans held it in peculiar veneration, and it was the scene of all their triumphal processions. By the cackling of geese the Romans were once roused to the protection of their Capitol, and this is often alluded to when slight means serve great ends.
- Cards**, various games with, 666-671.
- Carpets**, purchasing, 769; cleaning, 771.
- Carriers**, laws relating to, 801.
- Carthage**, a great maritime and republican city of Africa, founded about 900 years B. C. by the Phœnician princess Dido, and long the rival of Rome. Carthage existed for upwards of 700 years, and possessed during its palmy days a great part of Africa on the Mediterranean, as well as Spain, Sicily, and Sardinia. Its generals, and particularly Hannibal, pressed Rome so severely, that Cato, one of the wisest of the Romans, pronounced its destruction indispensable. His words, '*Delenda est Carthago*' ('Carthage must be destroyed'), have become proverbial. The power of the African republic was at last overthrown by Scipio Africanus, and the city ruined by fire. The Romans, in their hate, used to call the Carthaginians all that was treacherous; and from one of the names of the latter people, *Punica fides* (Punic faith) was made by their foes a lasting synonyme for 'faithlessness,' 102-106.
- Cartouche**, example of, in Archæology, 675.
- Cassandra**, a Trojan princess, who is said to have received the gift of prophecy from Apollo; but having afterwards slighted the god, was doomed by him to have all her predictions disbelieved. When she foretold the fall of Troy, accordingly, she was deemed insane. An unheeded prognosticator of evil is hence termed a Cassandra.
- Castalia**, a Parthian fount, sacred to the Muses, and a fertile theme of poetical allusions.
- Castor**, son of Leda, whom the enamoured god Jupiter is said to have wooed in the form of a swan. Leda bore at once two sons and two daughters—Castor, Pollux, Clytemnestra, and Helena, of whom the second and fourth were deemed children of Jupiter, and the other two of the husband of Leda. Pollux, on being elevated to a star, exhibited his love for Castor by seeking for the latter a share of his immortality, and it was granted to them to live six months alternately.
- Cathedrals and cathedral cities** of England, 224.
- Catholic Church**, the Roman, 399.
- Catiline** (Sergius), a noble Roman of great talents, but infamous character and habits. To gratify his ambition, avarice, and revenge, he rebelled against his country, but was overcome and slain in battle. The name of Catiline is used to express all that is evil in the character of a conspirator and liberticide, 108.
- Cato**, a name borne by several illustrious Romans. Cato, surnamed the Censor, was famous for his valour, temperance, wisdom, and eloquence. He studied and acquired the Greek tongue at the age of eighty. Fragments of his compositions yet exist.—Cato, surnamed Uticensis, was the great-grandson of the Censor, and made himself celebrated by his patriotic resistance to the usurpations of Julius Cæsar, to avoid falling into whose hands he ultimately stabbed himself, after reading Plato on the Soul's Immortality, 108.
- Catullus**, a Roman poet, whose pieces have much sweetness and feeling, though occasionally marked by immorality.
- Caucasian variety** of mankind, physical and mental characteristics of, 1; history of, 68.
- Causality**, faculty of, in Phrenology, 350.
- Cause and effect**, in Logic, 359.
- Cautiousness**, in Phrenology, 344.
- Caxton**, William, his connection with the introduction of printing in Britain, 707.

Celtæ or Celts, in Archæology, 677, 681.  
 Celtic family, characteristics of, 3.  
 Censors, two important Roman magistrates, who had the care of the manners and morals of the people.  
 Centaurs, a monstrous people of Thessaly, described as having the head, chest, and arms of men placed on the trunks of horses. A band of them being invited to a wedding-feast of the Lapithæ, a quarrel ensued, and a fearful battle took place, in which Hercules and Theseus peculiarly distinguished themselves in combating and defeating the Centaurs. Many sculptors, from the Greeks to the moderns, have used the chisel on this subject, which is indeed rich in the picturesque. The first use of horses for riding seems to have originated the fable of the Centaurs, but Pliny actually states that he saw one embalmed!  
 Central America, states of, described, 304.  
 Cephalus and Procris, a wedded pair, who, having each tried the other's fidelity by disguises, found that human nature is frail, and became content and happy. But Procris, uncured of jealousy, followed her husband one day to the chase, and was accidentally slain by him. The story of these lovers is often told and alluded to by the classical poets.  
 Cerberus, a dog with three heads, guardian of the infernal gate. Watchdogs, nay, guardian bipeds, frequently receive this name.  
 Ceres, the goddess of corn and harvests, daughter of Saturn and Vesta. She was worshipped everywhere for her bounties, having taught Triptolemus of Eleusis all the arts of agriculture, and sent him to disseminate them over the earth. At Eleusis, she also established the famous rites called the Eleusinian Mysteries, 87.  
 Chaos, the rude, shapeless mass of matter composing, according to the ancients, the yet unformed universe.  
 Chapel, in Printing, 715.  
 Charge-d'affaires (Fr.), in diplomacy, 45.  
 Charlemagne, his career, 115-118.  
 Charon, the ferryman who wafted the dead over the river Styx into the regions below. As the boatman demanded a 'consideration' for his services, it was customary for the ancients to place a small coin between the tongues of the dead.  
 Charybdis, a deep whirlpool in the Sicilian sea, opposite to the rock Scylla. The combined dangers of both led to the well-known saying—'*Incidis in Scyllam, cupiens vitare Charybdim*'—('Shunning Charybdis, you on Scylla strike'), which is familiarly applied in the same sense as the Scottish proverb, 'Out of the frying-pan into the fire.'  
 Chemistry, logic of the science, 367.  
 Chess, game of, 657-661; ancient chessmen, 686.  
 Chester, city, description and account of, 221.  
 Chevron, a term in heraldry, 47.  
 Chilblains, how to remove, 784.  
 Chili, description and account of, 309.  
 Chimæra, a fabled monster killed by Bellerophon, which had a triple head, composed of those of a goat, a lion, and a dragon, and which breathed flame. Any monstrous thing of fancy is now termed a chimæra.  
 Chimney on fire, how to extinguish, 775; smoky, how to cure, 777.  
 Chinese language, 32; history, manners, religion, literature, &c. 67.  
 Chivalry, institution of, 121  
 Chords, classification of, in Music, 745; progression of, 746; derived from the dominant, 751.  
 CHRISTIANITY, HISTORY OF, 394-400.  
 Christmas-day, festival of, 447.  
 Chronicle (Gr. *chronos*, time), a historical register of events in the order of time.  
 Church of England, 180; of Ireland, 180; of Scotland, 181; the statistics, &c. of.  
 Churches, the Roman Catholic, the Eastern, Protestant-Episcopalian, Presbyterian, &c. 399-400.  
 Cicero (Marcus Tullius), an orator of Rome, whose speeches against Catiline, Antony, and others, re-

main imperishable monuments of his powers. His eloquent denunciations saved Rome from the tender mercies of Catiline, and he was termed by the people *the father of his country*. After serving the state in the highest situations at home and abroad, and suffering exile for his attacks on the bad, he took the side of Pompey against Cæsar; but the latter, on becoming victor, treated Cicero with much respect. However, when Cæsar was slain, Antony, the bitter foe of the orator, acquired a fatal degree of power. At length Antony despatched assassins on the track of Cicero, and soon after his bleeding head was brought to Rome, where the wife of the master-murderer tore out the once persuasive tongue in remorseless spite.  
 Cicerone (Ital.), an individual who acts as a guide or pointer out of interesting objects to travellers.  
 Cimmerian, a local epithet for the natives of the district now called the Crimea, and some parts of which were thought to be so dark, that 'Cimmerian gloom' has become a proverbial phrase.  
 Cincinnatus, an illustrious Roman, who was taken from the plough, which he left with regret, to serve and save his endangered country. His task fulfilled, he again contentedly retired to his farm.  
 Circe, a witch of semi-divine origin, whose irresistible enchantments drew many into her power, only to be changed, after a short career of voluptuousness, into filthy swine. Circe is evidently an emblem of debasing pleasure.  
 Circle, properties of the, in Geometry, 610.  
 Circumcision, festival of, 438.  
 Circus, the place where shows were exhibited at Rome.  
 Cities, historically and socially considered, 38.  
 Civil society, construction and constitution of, 38.  
 Civility, duty of, 456.  
 Clarinet, musical instrument, 766.  
 Classic (Lat. *classis*, a class). The highest class among the Romans were denominated, by way of pre-eminence, *classici*; hence the application of the term to authors of the highest or first class, whose works are regarded as models or authorities. A writer is therefore said to be *classical* if public opinion has placed his productions in the first class; and a painting is said to be *classic* when its arrangement is such that all the parts or accessories are suitable to the general design.  
 Cleanliness, duties regarding, 450.  
 Cleopatra, a name borne by several princesses of Egypt, and rendered particularly famous by one whose surpassing beauty enslaved Mark Antony, and led to his ruinous contention with Cæsar Augustus. When Antony fell, Cleopatra applied an asp to her breast, and died from its venomous bite, 110.  
 Clients and Patrons, in Roman History, 98.  
 Climax (Gr. *climax*, gradation). In rhetoric, an ascent from the least important object or proposition to that which is calculated to make the greatest impression on the mind of the hearer or reader. Anticlimax is the term employed when the ideas sink in succession: nearly the same as bathos.  
 Clio, the Muse who presided over history, 87.  
 Cloacina, a goddess to whom the Romans assigned the care of all the refuse of their city: see also Cloacæ, Vol. I., 476.  
 Closes, or Cadences, in Music, 760.  
 Cloth, incombustible, 780.  
 Clotho, one of the Fates, who held the distaff from which was spun the thread of life, 87.  
 Clyde, scenery of the, 232.  
 Clytemnestra, wife and murderer of Agamemnon, and the victim of her own son's revenge.  
 Cockroaches, how to destroy, 774.  
 Codrus, an Athenian king, who, prompted by an oracle, gave up his life to save his country, 85.  
 Colosseum, a gigantic amphitheatre at Rome. See vignette to No. 57.  
 Colonial possessions of Britain, statistics of, 189.  
 Colossus, a brazen image placed with its feet on the

- two moles of the harbour of Rhodes, and of such magnitude, that ships passed easily between its legs. The term colossal has become firmly established in modern languages.
- Combative, in Phrenology, 341.
- Comitiæ, public assemblies of Rome, 98.
- COMMERCE, 497-503.
- Commercial statistics of Britain, 185-187.
- Commons, constitution of the House of, 177.
- Company, see commercial terms, 499.
- Comparison, faculty of, in Phrenology, 350.
- Composing, in letterpress-printing, 710.
- Composition, law of in animated nature, 379.
- Concentrativeness, in Phrenology, 340.
- Concertina, a musical instrument, 768.
- Conjunction, in Grammar, 580.
- Connoisseur (Fr. *connaisseur*, to know), originally applied to one versed in the fine arts; but now employed indiscriminately to one well acquainted with any particular object or study.
- Conscientiousness, in Phrenology, 345.
- Consonants, various classes of, 19.
- Constantinople during the Middle Ages, 125.
- Constructiveness, in Phrenology, 342.
- Consul, the highest Roman magistrate. This office was held annually and conjunctly by two individuals, who conducted the wars of the state, presided over the senate, and held, in short, nearly absolute power.
- Consumption, nature and design of, in Political Economy, 494; different kinds of, 495.
- Contiguity, the law of, in metaphysics, 328.
- Contraband (Ital. *contra*, against; *bando*, a proclamation), in commerce, goods exported from, or imported into, a country against its laws; smuggled, in common language.
- Contralto (Ital.), in Music, 738.
- Corinth, a famous city of Greece, situated on the isthmus between the Gulfs of Ægina and Lepanto, and remarkable in classical times for its power and opulence. *Corinthian brass* is frequently alluded to, and is said to have been an alloy accidentally formed when the city was burned by the Romans in the second century, A.D. The common adage, '*Non cuius homini contingit adire Corinthum*'—('It is not every man's luck to visit Corinth'), is supposed by Suidas to refer to its difficulty of access by sea.
- Cork, city, description and account of, 251.
- Cornelia, a noble Roman lady, who, though her sons were put to death for their turbulence, was so proud of them that it was her boast to be simply named 'The mother of the Gracchi,' 104.
- Corno or French-horn, 767.
- Corno, or French-horn, 767.
- Cornopean or Cornet-à-piston, 767.
- Corns, how to remove, 784.
- Coronet, literally, a little crown, in heraldry, 47.
- Corsellis, first printer in England, 707.
- Corydon, a name in Virgil's pastorals, often applied to shepherds.
- Coryphæus (or Choryphæus), a title formerly given to the leaders of choral bands, and now frequently assigned to leading men of any description.
- Cosmetics, in personal economy, 784.
- Counterpoint, in musical composition, 762, 764.
- Counter-tenor, in musical composition, 738.
- Courtesy and respect, duty of, 457.
- Courts of law, English, 60; Scotch, 63.
- Covenant, the National, of Scotland, 141.
- Coventry, description of, 219.
- Cowry (Germ. *Kouri*), a small shell of the genus *Cypræa*, used in Africa, in India, and the Indian islands in lieu of coin in smaller payments: one hundred are equivalent to a penny, 503.
- Cream, cold, recipe for, 784.
- Credit, nature of, in Commerce, 500.
- Crete.—The island of Crete was chiefly renowned of old for its labyrinth, laws, luxury, and lies. The name of a Cretan, indeed, became a byword for falsehood.
- Cribbage, game of, 669.
- Cricket, practice and rules of, 651-653.
- Crime, statistics of, 559; in Britain, 192.
- Criticism (Gr. *krino*, I judge), in rhetoric, the art of judging with propriety concerning any object or combination of objects; usually limited to literature, philology, and the fine arts.
- Croesus, a king of Lydia, supposed to be the richest of mankind, and desirous of being thought the happiest. Solon, the Athenian philosopher, told him that wealth did not insure happiness, and that no man could be safely called happy before death. Croesus disliked this plain speaking, but when overcome by Cyrus, and led out to execution, he acknowledged aloud its truth. Cyrus, struck himself by the circumstance, pardoned him.
- Cromlechs, in Archæology, 683.
- Cromwell, his career, 144-147.
- Cross-hatching, in Engraving, 723.
- Crotchet, in musical time, 739.
- Crusades, the, 119-124.
- Cuirass (Fr. *cuir*, leather), a covering for the breast, originally made of leather, but now of quilted linen, woollen, steel-plate, or any other material.
- Cultivation, self, as a mental desire, 334.
- Cupid, god of Love, and son of Venus, queen of Beauty. He is represented as a winged boy, naked, and armed with a bow and arrows.
- Curiosity metaphysically considered, 334.
- Curling, game of, 649; laws for, 650.
- Currency of the United Kingdom, 188, 507.
- Customs, and customhouse, in Commerce, 502.
- Cutlery and other hardwares, in household economy, 770.
- Cybelé, a goddess worshipped with many mystic rites, and usually painted with a turreted crown, keys in her hand, and a lion-drawn chariot.
- Cyclops, a race of one-eyed giants, who acted as assistants to the smith-god Vulcan, and devoured human beings.
- Cymbals, in Music, 768.
- Cynic (Gr. *κύν*, a dog), a Greek sect of philosophers, so called from their snarling humour, and disregard of the conventional usages of society.
- Cyprus.—The island of Cyprus, from its luxurious fertility, was supposed to be the residence of the goddess of Beauty and Pleasure, and from this cause the epithet 'Cyprian' has acquired a licentious meaning.
- Cythera, an islet off the Morea, sacred to Venus, and from which she is often called Cytherea, or the Cytherean goddess.
- Czar or tsar (*Cæsar*), the title given to their monarch or emperor by several Slavonic tribes.
- Dædalus, an Athenian of great skill in the mechanical and fine arts, to whom some ascribe the invention of the wedge, the axe, the wimble, and the level. He is said also to have formed the many-pathed labyrinth of Crete, in which he himself was ultimately confined with his son Icarus. Not being able to get out of his own trap, he made wings for himself and Icarus, with which they flew away; but the too-daring youth rose so near the sun that the waxen fastenings of the wings melted, and he fell into the sea. Dædalus is the nominal prototype of all ingenious mechanics.
- Daguerreotype, art of, 733.
- Damocles, a courtier, who, having loudly flattered Dionysius of Sicily on the score of his wealth and fortunate greatness, was placed for a time, by way of trial, upon the tyrant's throne. Damocles gazed a while with delight on the splendour around him; but, looking up, he saw a sword suspended above his head by a single hair, and his fancied happiness vanished. This incident is often referred to in illustration of the perils and turmoils of greatness.
- Damon and Pythias, two friends of such constancy, that when the former of them was doomed to die, and sought for a respite, that he might go home and settle his affairs, the latter offered his life as a

INDEX, AND GLOSSARY OF TERMS.

Numa, a sovereign of Rome, proverbial for legislative skill, which he affected to owe to the counsels of a supernatural and secret visitant named Egeria.

Number, organ of, in Phrenology, 348.

Numeration, in Arithmetic, 594.

Nymphæ, a general term applied to all the minor goddesses of the land and sea, such as the Dryads, Naiads, and Nereids. The nymphs were held not to be immortal, but to live for several thousand years.

Oberon, king of the fairies, 420.

Oceans, geographical account of, 281.

Oceanides, sea-nymphs, daughters of Oceanus, and numbering several thousands. Their father Oceanus, like Cœlus the Heaven, and Terra the Earth, was one of the primitive divinities, and was totally different from Neptune, being the creation of a much earlier mythology.

Octavo, a printer and bookbinder's term, 711.

October, festival Calendar for, 443.

Odin, in Scandinavian mythology, 417.

Œdipus, a king of Thebes, son of Laius and Jocasta. Being exposed in youth, he had the misfortune to kill his father and marry his mother ere he discovered his parentage. These events made his story a sorrowful theme for the poets; but his name is now chiefly familiar in the sense of an expounder of riddles, because he solved the enigma proposed by a talking monster called the Sphinx, and put an end to its ravages.

Olympia, a town of Elis in the Peloponnesus, where the famous Olympic games were celebrated. These were of great antiquity, and comprised not only athletic exercises of every kind, chariot-racing, and the like, but also contentions in poetry, eloquence, and the fine arts. The celebration took place at the end of every four complete years, and hence it became the fixed practice to measure time by these intervals, called Olympiads, 86.

Olympus, a mountain of Thessaly, which, from its altitude, the ancients conceived to reach the heavens, and which they made the home of the gods.

Oneiromancy (Gr. *oneiros*, a dream, and *mantia*, divination), divination or foretelling of events by dreams; from the same source we have oneirology, the doctrine and theory of dreams.

Ophicleide, musical instrument, 767.

Opinions, duties regarding the forming of, 476.

Or (Lat. *aurum*, gold), a term in heraldry, 47.

Oratorio (Ital.), a sacred musical composition, consisting of airs, recitations, duets, trios, choruses, &c. the subject of which is generally taken from Scripture.

Orcus, a name of Pluto, frequently used to signify the nether regions.

Order, organ of, in Phrenology, 349.

Oreads, the goddess-nymphs of the mountains.

Orestes, the son of Agamemnon and Clytemnestra, and the avenger on the latter of his sire's murder. Pursued in consequence by the Furies, Orestes could find peace no where, though tenderly consoled and supported by Pylades, whose name and his own have become proverbial for bosom friendship. Orestes was at length purified from stain by bringing the Taurian statue of Diana to Greece.

Organ, musical instrument, 767.

Orgies (Gr.), frantic revels at the feast in honour of Bacchus, which was held during the night; hence the familiar term 'nocturnal orgies' for any midnight scenes of riot and dissipation.

Oriflamb or oriflamme, the ancient royal standard of the kings of France—

'And be your *oriflamme* to-day the helmet of Navarre.'

Orion, a gigantic personage, who, after various adventures on earth, had the honour of being elevated to a place among the constellations.

Orpheus, the most famous of the early poets and musicians of Greece, who, by his art, could not only 'charm the savage brest,' but cause mountains to

dance and streams to pause in their course. On the death of his wife Eurydice, he went to seek her, and so enchanted Pluto with his strains, that the god gave back his spouse to him, only stipulating that he should not look upon her till the earth was reached. But Orpheus turned to gaze, and Eurydice was lost.

Orris-root, the root of the *Iris Florentina*, used in perfumery. See the toilet.

Osiris, a great Egyptian deity.

Ossa, a lofty mount of Thessaly, said to have been moved by the giant Titans, when they sought to scale the heavens. Hence the well-known allusion to the piling of Pelion, another hill, on Ossa.

Ostracism, banishment from Athens, 90; also applied generally to exile, whether voluntary or compulsory.

Ovid, a poet of Rome, noted for the ease and elegance of his verse, but stained by immoralities of thought and diction.

Pactolus, a river of Lydia, the sands of which were said to be converted into gold when Midas dipt his hands in them.

Pæan, a hymn sung in honour of the Pythian Apollo.

PAGAN RELIGIONS—PAGANISM, 401-408.

Pain, metaphysically considered, 332, 352.

PAINTING, ART OF, 638-640.

Palestine, ancient history of, 75.

Palilogy (Gr. *palis*, again, and *logos*, a word), in rhetoric, the repetition of a word or part of a sentence for the sake of effect, as

—'The sleep—

Sleep that knits up the ravelled brow of care.'

Palinurus, a pilot who has given a name to his craft from his skill in guiding the bark of Æneas.

Palladium, a famous colossal statue of Pallas-Minerva, on which the city of Troy, in which it stood, depended for preservation. It was stolen by the Greeks. The importance of the statue to Troy has originated such phrases as the 'Palladium of our liberties,' applied to important privileges, statutes, and the like.

Palm-Sunday, festival of, 437.

Pan, the god of shepherds, huntsmen, and rustics generally, and son of Mercury. He was painted like the satyrs, having horns and the limbs of a goat. He invented the flute with seven reeds. Pan was worshipped very extensively, but particularly in Arcadia, where he had an oracular temple on Mount Lyceus, 87.

Panacea, the skilful daughter of the medicine-god Æsculapius, from whose name originated a word signifying a universal cure.

Pandora, the first woman, according to some ancient writers. Jupiter, wishing to punish the Titan Prometheus, caused Pandora to be made of clay, and each of the deities bestowed some personal gift on her. She was then sent with a closed box to Prometheus, but he suspected some artifice, and sent her away. His brother was less cautious, and wedded Pandora, from whose box, when opened, there issued all the ills that have since afflicted mankind. As a cure for these ills, Hope only remained upon earth.

Pantheism (Gr. *pan*, all; and *theos*, God). In metaphysical theology, this term is applied to the theory which identifies nature or the universe with God; pantheist, one who adopts the theory of Spinoza, that the universe, in its complicated but harmonious relations and developments, is God.

Pantheon, a temple of Rome, dedicated, as its name implies, to all the gods.

Paper-hangings, how to clean, 772.

Paphos (now Bafø), a city of Cyprus, from which Venus, to whom that isle was sacred, frequently receives the name of the Paphian goddess.

Paraguay, account of, 310.

Parallel lines, in Geometry, 612.

Parcæ, the powerful goddesses called the Fates, who were named Clotho, Lachesis, and Atropos. The

- decrees of the Fates were unchangeable even by the greatest of the gods, and they were worshipped with more true devoutness, perhaps, than any other supposed divinities, 87.
- Paris, son of Priam of Troy, exposed in infancy because his mother Hecuba dreamt that she had brought forth a fatal torch. Educated as a shepherd on Mount Ida, Paris was chosen to decide on the comparative beauty of Juno, Minerva, and Venus, when these deities were rivals for a golden apple, inscribed by the goddess Discord with the words, 'To be given to the fairest.' Paris decided for Venus, who so favoured him in consequence, that he persuaded Helen, the most beautiful woman of the age, to fly with him to Troy. But all the Greek princes joined in resenting the injury, and Paris proved, indeed, the fire-brand by which Troy was ruined. The judgment of Paris and the apple of Discord are the subjects of many classical allusions.
- Parliament, British, origin of, 131; constitution of, 177.
- Parnassus, a very lofty mountain of Greece, to which, as the supposed favourite seat of Apollo and the Muses, poets have looked in all times for inspiration.
- Parsing, in English Grammar, 580.
- Parthenon, a splendid temple of Minerva at Athens, adorned by the works of the sculptor Phidias. See Vol. I., p. 435.
- Passover, a solemn festival of the Jews in commemoration of their deliverance from the destroying angel on the night previous to their departure from Egypt, when the first-born of the Egyptians were put to death, and the houses of the Israelites *passed over*—they being marked with the blood of the paschal lamb.
- Patagonia, territory of, 318.
- Pathos, in literary compositions, 692.
- Patriarch, patriarchal society, 36.
- Patroclus, the bosom-friend of Achilles, slain by Hector before the walls of Troy.
- Patrons and clients, Roman, 98.
- Pawnbroking, benevolent, 540.
- Peace of mind, importance of, 463.
- Pedestrianism (Lat. *pes*, a foot), feats in, 644-647.
- Pegasus, a winged horse given by Minerva to Bellerophon when he went to combat the monster termed the Chimæra. Requiring a lofty flight, the poets frequently choose to imagine their motions aided by a Pegasus.
- Pelion, a Thessalian mount, on which Ossa was piled when the Titans sought to scale heaven.
- Peloponnesus, the ancient name for the Morea.
- Pennates, a class of inferior gods who presided over the inmost recesses of households.
- Penelope, wife of Ulysses, king of Ithaca, famous for her fidelity to her husband during his long absence, despite the assaults of numerous importunate suitors. To deceive these, she said that she would wed when a certain piece of tapestry was finished by her, but the work done by day the chaste matron undid by night. Hence the phrase of Penelope's Web, applied to cases where progress is similarly retarded.
- Peninsula (Lat. *penē*, almost, and *insula*, an island), a geographical term applied to any projecting portion of land connected with the mainland by a narrow neck or isthmus; applied *par excellencē* to Spain and Portugal as the grand peninsula of Europe.
- Peninsular war and campaigns, 169.
- Pentateuch, the, history of, 386.
- Penthesilea, a queen of the Amazons, proverbial for her boldness in war, and slain by Achilles before Troy.
- Pericles, a renowned warrior, statesman, and orator of Athens, 91.
- Peripatetic Sect.—The pupils of Aristotle, so named (from the Greek) because instructed by him while walking.
- Perseus, son of Danae by Jupiter; exposed in infancy with his mother in a small bark, but preserved to fulfil the decrees of Fate by accidentally killing his grand sire. Perseus became a renowned hero, slaying the Gorgon Medusa, among other feats, by the aid of Pluto's invisible helmet and Minerva's shield. He also relieved Andromeda, an Ethiopian princess, from a sea-monster, to which she was exposed in chains. After his death, Perseus received the honours of a demigod, and poets and painters have dwelt much on the supposed incidents of his career.
- Persians, the ancient, 79; Persian Empire, 79.
- Perspective Drawing, 627.
- Persuasion, in Rhetoric, 698.
- Perth, description and account of, 240.
- Peru, description and account of, 308.
- Petronius (Arbiter), a favourite of Nero, often named in connection with gaieties and revels, from his being the caterer for amusement (*arbiter elegantiarum*) to that prince.
- Phæton, son of the sun-god Phœbus-Apollo by the nymph Clymene. Taunted as of unknown birth by his youthful companions, Phæton is said to have visited the palace of the sun, and to have received from his sire a solemn promise that whatever he asked should be granted. The vain youth asked to drive the chariot of the sun for one day, and, bound by oath, Phœbus was reluctantly forced to comply. The issue was that the fiery steeds became unmanageable; and to prevent a universal conflagration, Jupiter struck Phæton to the earth with a thunderbolt. His death was so deeply mourned by his sisters, that in pity they were changed to poplars. Phæton is a byword for rash ambition.
- Phalaris, a cruel Sicilian tyrant, who caused a brazen bull to be made for the purposes of torture, and consigned to it the inventor Perillus as the first victim.
- Pharos, an islet in the bay of Alexandria, on which was a splendid lighthouse, deemed by the ancients one of the seven wonders of the world; sometimes used as a general term for a lighthouse.
- Pharsalia, a place in Greece where the republican liberties of Rome received the final blow from the hands of Julius Cæsar, his great opponent Pompey being there conquered by him.
- Phidias, the most illustrious of Greek sculptors.
- Philip, a famous Macedonian monarch, father of Alexander the Great. By his great valour and consummate address Philip enlarged his dominions, and gained a fatal ascendancy over the free republics of Greece. Trained in youth in the schools of Thebes, he polished and disciplined his rude subjects, and raised them from a secondary to a primary position among their neighbours. Philip was an ambitious and unprincipled man, though capable of generous and even noble actions. His barbarian-like indulgence in drinking has been made memorable by the words of a claimant for justice at his hands: 'I appeal from Philip drunk to Philip sober,' was the reproof, and he bore it calmly. From the denunciations of him by Demosthenes, such oratorical invectives have been called *Philippicæ*.
- Philology (Gr. *philō*, I love, and *logos*, a word or discourse), the science which treats of language in general; its history, progress, and development among the various nations of the globe, 17.
- Philomela, sister of Progne, who was wife to Tereus, king of Thrace. While bringing Philomela to see her sister, Tereus offered violence to her; and after cutting out her tongue to prevent discovery, confined her in a lonely castle. He then told Progne that her sister had died by the way, but the former detected the falsehood by means of a piece of tapestry wrought by Philomela. The infuriated wife of Tereus slew and served up to him his own son in a dish, on discovering which he would have slain her, but was on the spot changed into a hoopoe, while the son's remains became a pheasant, Progne a swallow, and Philomela a nightingale. The nightingale yet bears this name, and is supposed by the poets to wail her sad fate in the sounds 'Teru! Teru!'

## INDEX, AND GLOSSARY OF TERMS.

- Philoprogenitiveness**, in Phrenology, 340.
- Phoebe**, a name given to Diana in the character of the moon, 86.
- Phoenicians**, history of, 73; commerce of, 74.
- Phormium tenax**, or New Zealand flax, 287.
- Photogenic Drawing** or Photography, 732.
- PHOTOGRAPHY**, 732-736.
- PHRENOLOGY**, 337-352.
- Physiology**, logic of the science, 367.
- Pianoforte**, musical instrument, 768.
- Pica**, a variety of type, in Printing, 709.
- Piccolo**, musical instrument, 766.
- Picture-frames**, how to clean, 772.
- Pieria**, a spot in Thessaly, which gave the epithet Pierian to the Muses.
- Pindar**, a poet of Thebes in Bœotia, justly regarded as the prince of lyric poetry. His odes are without parallel for simplicity and fire.
- Pirithôus**, an ancient hero, betwixt whom and Theseus so strong a friendship existed, that the pair are quoted as models of that sentiment.
- Pittacus**, one of the Seven Wise Men of Greece.
- Pix** (Lat.), the little box or chest in which the consecrated host of the Roman Catholic Church is kept. A box kept at the British Mint, in which a small sample of the coins struck is deposited, in order to be assayed and compared with a standard preserved in the Exchequer. This operation, called 'trial of the pix,' is performed in presence of certain members of the Privy-Council, the officers of the Mint, and a jury of the Goldsmiths' Company.
- Planetary system**, design in, 369.
- Plants**, how to dry and preserve, 781.
- Plato**, a philosopher of Athenian descent, whose name stands at the head of his class among the Greeks. He was a disciple of Socrates, and founded the school of Academics. Plato laboured to construct a great system of metaphysics, morals, and policy, and displayed his own genius in eliciting many profound isolated truths; but, as a whole, his system is but a maze of ingenious conjecture. The phrase 'Platonic love,' indicating an affection seated merely in the mind, is derived from some principles evolved in his account of an imaginary and perfect republic.
- Pleides**, the seven daughters of Atlas, placed at their death among the constellations.
- Pliny**.—Two members of the Pliny family, uncle and nephew, have left brilliant names in Roman literature. The elder Pliny wrote many works, but his 'Natural History,' a production alike full of truths and absurdities, has alone been preserved; and of the younger Pliny, the 'Letters' are still extant. The uncle perished in an eruption of Vesuvius, A. D. 79.
- Plutarch**, a Greek historical biographer, whose valuable works have given a name to many compositions of the same class.
- Pluto**, one of the sons of Saturn, and king of the infernal regions. He married Proserpine, the daughter of Ceres, having borne her off from Sicily while gathering flowers—'herself a fairer flower.' Black bulls were most frequently sacrificed to Pluto, who is represented as a grim figure, with a two-pronged trident in his hand, and keys, to indicate his close wardship of the dead. He sat on a throne of sulphur, and around him were his gloomy courtiers, the Fates, the Furies, and other infernal powers. Dis, Aëes, Orcus, are names sometimes given to Pluto, 86.
- Plutus**, the god of riches among the ancients, painted as blind.
- Plymouth**, naval station of, 225.
- Poetry**, in Rhetoric, 701.
- Politeness**, good manners, 457.
- POLITICAL ECONOMY**, 481-496.
- Pollux**, son of Leda, and brother to Castor, raised to a place among the stars.
- Polygamy** (Gr. *polys*, many, *gamé*, marriage), 33.
- Polyhymnia**, the muse of singing and rhetoric, 87.
- Polynesia**, geographical account of, 288.
- Polyphemus**, a gigantic Cyclop, whose one eye Ulysses burnt out with a firebrand, on being captured by the monster. The story is told in the 'Odyssey.'
- Poly-synthetic** (Gr.), a term applied to the aboriginal American languages, from their excessive tendency to agglutinate syllables into long words, 32.
- Pomades**, recipes for, 784.
- Pomatum**, how to make, 784.
- Pomona**, a Roman deity, who had charge of gardens and fruit-trees. She had vowed to live single; but changing himself into an old woman, as the pretty fable runs, Vertumnus, the god of spring, induced her to change her purpose.
- Pompey**.—The family of Pompey was a famous one at Rome, but chiefly rendered eminent by one member, called Pompey the Great. The conquests of this Roman were of vast extent, and his triumphs numerous, while his character is described as noble in the extreme. But though Pompey married the daughter of Julius Cæsar to cement their friendship, two men of such aspiring minds could not co-exist in peace in Rome. They turned their arms against one another, and at Pharsalia Cæsar proved the conqueror. Pompey fled to Egypt, and was there basely and ungratefully murdered, 107-109.
- Poor**, arrangements for, in England, 517; in Scotland, 521; in Ireland, 523.
- POOR-LAWS**, 517-524.
- Pope**, origin of the term and office, 398.
- POPULATION**, theories respecting, 513-517.
- Portsmouth**, naval station of, 222.
- Portugal and Spain**, description of, 195.
- Potashes**, manufacture of, 779.
- Praxiteles**, a native of Cnidus, famous for his skill in statuary.
- Preposition**, in Grammar, 579.
- Presses**, printing, varieties of, 714-720; copperplate, 728; lithographic, 732.
- Priam**, king of Troy, an aged man when the Greek princes besieged and took his city.
- Priapus**, a son of Bacchus and Venus, whose statues, set up in gardens, were of a very offensive nature.
- Pride** and self-respect, 459.
- Prince Edward's Island**, account of, 296.
- PRINTING, LETTERPRESS**, 705-720; origin and history of, 705-711; process of, 711-720. Plate Printing, 728; Lithographic Printing, 732.
- Priscianus**, a grammarian of the Greek Empire, whose name is often quoted in reference to correctness of language.
- Procrustes**, a robber chief of Attica, who was wont to bind travellers down to a bed, and to cut off a portion of their bodies, or to rack these out, if they chanced in either way not to fit the couch. He was killed by Theseus. The bed of Procrustes is a familiar allusion.
- Production**, in Political Economy, 496.
- Profanity**, crime of, 416.
- Progression**, arithmetical, 597; geometrical, 599.
- Prometheus**, one of the Titanic race, famed for his knowledge and address, and capable of deceiving Jupiter himself. To punish a fraud exercised upon him, that god took away fire from mankind, but Prometheus clomb the heavens and regained the element by theft. Jupiter, still more provoked, sent down Pandora with a box of ills, but Prometheus was too cautious to accept the gift. The supreme deity, however, chastised him by chaining him to Mount Caucasus, and sent a vulture to feed perpetually on his liver, which still remained undiminished. Hercules at length set the sufferer free. The stealing of the fire is supposed to refer to the discovery of its use; and Prometheus, whose story is often referred to, is called the inventor of many useful arts.
- Pronoun**, in Grammar, 578.
- Propertius**, one of the secondary Roman poets, author of many beautiful though not perfectly moral compositions.

- Prophets, the books of the, 383.  
 Proportion, or Rule of Three, 600.  
 Propositions and assertions, in Logic, 356.  
 Proserpine, the daughter of Ceres, and wife of Pluto, permitted to spend half the year in heaven at her mother's intertreaties. The changes of the moon are supposed to be indicated here. Proserpine was universally worshipped, sometimes under the name of Libitina, Hecate, and Libera.  
 Proteus, a sea deity, who possessed the gift of prophecy, but was difficult of access, and unless properly chained, had the power of assuming different shapes to elude his interrogators. Proteus affords a favourite similitude to express a change of form or purpose.  
 Provost, chief municipal magistrate in Scotland, functions of, 45.  
 Prussia, geographical description of, 207.  
 Psaltery, a stringed instrument, 768.  
 Psyche, a beautiful nymph, whom Cupid married and long lived with in a state of bliss. Venus put her to death, but Jupiter in pity made her afterwards immortal. As Psyche means the soul, this story is thought to present a personification of it; and to indicate the light ethereality of the soul, Psyche is painted with the wings of a butterfly.  
 Ptolemy.—The Ptolemies were a race of sovereigns, descended from a general of Alexander the Great who obtained the throne of Egypt.  
 Punctuation, in Grammar, 590.  
 Punica Fides.—The Romans in their enmity called the Carthaginian or Punic people extremely treacherous, and hence sprung the phrase *Punica fides* (Punic faith), to express utter faithlessness.  
 Pygmalion, a sculptor of Cyprus, who, having made a beautiful ivory statue of a female, fell in love with his own work, and by his prayers moved Venus to animate it. This fable is the theme of frequent allusion.  
 Pylades, a prince of Phocis, bound so closely in the bands of friendship with Orestes, that they are cited as exemplars of that feeling in its strongest form.  
 Pyramids of Egypt, 674; vignette to No. 55.  
 Pyramus, a youth of Babylon, attached to Thisbe, whom, from the hostility of their parents, he could only converse with through a chink in the wall betwixt their habitations. The lovers, however, appointed to meet at the tomb of Ninus. Thisbe arriving first, was frightened away by a lioness, which, with bloody jaws, tore a scarf dropped in her flight. Pyramus saw this article, and believing Thisbe dead, slew himself. The distracted maiden, on her return, followed him to the tomb.  
 Pyrrha, wife of Deucalion, and saved with him from the great Thessalian deluge. By throwing stones behind her she is fabled to have re-peopled the earth with women, as Deucalion supplied it with men.  
 Pythagoras, a celebrated philosopher of Samos, who, amid many useful doctrines, taught the curious one of the transmigration of souls, and even said that he remembered what bodies he had occupied before. He made his pupils keep silence for many years. The greatness of his real talents is shown by his assertion, that the planets move round the sun as a centre—an idea laughed at in his own time, but since established as a certainty.  
 Pythia (Pythoness), the priestess of Apollo at Delphi, who, inspired by vapours from the earth, delivered, amid convulsive writhings, the oracles of the deity. See Delphic oracle, 88.  
 Python, a serpent killed by Apollo, from which his priestess received her name, as he himself was called the Pythian god.  
 Quadrilateral or four-sided figures, in Geometry, 613.  
 Quadrilles, various, 672.  
 Quartett (Lat. *quartus*, four), in Music, 765.  
 Quarto, a printer and bookbinder's term, 711.  
 Quaver, semi, and demisemi, in Music, 739.  
 Quiddity, an obsolete scholastic term for essence; quiddit, a subtlety.  
 Quintett (Lat. *quintus*, five), in Music, 765.  
 Quoits, game of, 655.  
 Rack, an ancient instrument of torture, 687.  
 Racket, game of, 655.  
 Railways of Great Britain and Ireland, 188.  
 Rank and condition, duties regarding, 477.  
 Ranks and titles, 48.  
 Ratiocination or argumentative inference, in Logic, 858.  
 Ratios, in Arithmetic, 599.  
 Rats, how to get rid of, 774.  
 Razors and razor-pastes, 782.  
 Recreations and amusements, duties regarding, 477.  
 RECREATIONS, OUT-OF-DOOR, 647-656.  
 Reels, Scotch, 672.  
 Reflex actions, 322.  
 Reformation, the, in Britain, 135.  
 Regulus, a Roman consul, who, in warring with Carthage, was taken prisoner, and afterwards sent home to negotiate a peace. Aware of the reduced state of their enemy, Regulus advised the Romans not to agree to a cessation of hostilities. The noble prisoner thus sealed his own doom, as he was bound, if peace was not obtained, to return to Carthage. He did so, and underwent, after cruel tortures, the horrible death of being shut up in a barrel pierced on all sides with sharp spikes. His devotion to his country and his promise have gained him an undying name; see History of Rome.  
 Religious obligations, 479.  
 Rent or price of land, in Political Economy, 493.  
 Reptiles, design in the structure of, 375.  
 Republics, republican governments, 42.  
 Revolutions, in Civil Government, 43.  
 Rhadamanthus, brother of Minos, and so famous for his equity on earth, as to have been appointed one of the judges of the dead.  
 RHETORIC AND BELLES LETTRES, 689-704.  
 Rhythm or measure, in Music, 739.  
 Richard Cœur de Lion, 131.  
 Roads of Great Britain and Ireland, 188.  
 Rogation Sunday, origin of, 439.  
 Roman antiquities in Britain, 685.  
 Roman Catholic Church, 399.  
 ROME, HISTORY OF, 97-112.  
 Romulus and Remus, the two brothers who founded Rome, were fabled by their proud descendants to be the sons of Mars by a princess of Italy. They were exposed in infancy, but were saved and suckled by a she-wolf. The twins, on reaching manhood, resolved to found a city; but, for a trifling offence, Remus was slain by his brother. Romulus, however, with a band of fugitives and criminals, founded Rome; and as the neighbouring tribes despised his followers, he carried off mates for them from among the women of the Sabine nation. This abduction was often adverted to by the descendants of its authors. Romulus reigned thirty-nine years, and was then carried up to heaven, according to a story invented, most probably, to conceal his assassination. He received divine honours after his death, 98.  
 Roscius, a Roman actor of such celebrity, that every distinguished follower of that profession has received his name.  
 Roses, war of the, in English history, 133.  
 Rosicrucians, account of the, 432.  
 Rubicon, now Rugone, a small stream of Italy, which, after long hesitation, Julius Cæsar crossed, thus throwing off allegiance to the Roman senate, and affording a lasting simile for the taking of any decisive and hazardous step.  
 Running, as a gymnastic exercise, 644.  
 Russia, geographical description of, 207.  
 Sabines, a primitive Italian people, from among whom Romulus carried off wives for his followers on founding Rome.

INDEX, AND GLOSSARY OF TERMS.

- Sackbut or Trombone, 767.  
 Sadler, his theory of population, 515.  
 Sallust, a Roman historian, whose works, though not lengthened, are justly valued for their style and accuracy.  
 Sappho, a famous poetess of Lesbos, whose scanty fragments indicate extraordinary powers, and who was so tortured by love as to throw herself into the sea.  
 Saracens, empire of, 115.  
 Sardanapalus, the last of the Assyrian monarchs, noted for his luxury and effeminacy. His officers having conspired against him, and besieged him in Nineveh, he set fire to his palace, and was consumed in the flames, with all his slaves, concubines, and treasures, 77.  
 Saturn, son of the heaven and earth, and supreme ruler of the earth till he was dethroned by his son Jupiter. Saturn afterwards fled to Italy, and so cultivated there the arts of peace and simple industry, that his reign was called the Golden Age, 86.  
 Saturnalia, festivals held in honour of Saturn, and intended to commemorate the freedom and equality which prevailed in the Golden Age, when Saturn was king. From the privileges enjoyed during these holidays by the poor man and the slave, any revels where a free and levelling spirit is displayed have been called Saturnalia.  
 Satyrs, minor deities of the country, shaped like goats inferiorly, and having horns on their head and long hair over the body, 87.  
 Savings' banks, 529-533.  
 Sax-horn, musical instrument, 767.  
 Scale, the major, in Music, 737; the minor, 742; intervals of, 742.  
 Scales, construction of, in Geometry, 616.  
 Scandinavia. See Norway and Sweden, 206.  
 Scandinavian superstitions, 417.  
 Schoeffer, inventor of letter-founding, 706.  
 Sciences, logic of the, 364.  
 Scipio, the patronymic of an illustrious family of Rome, one member of whom, surnamed Africanus from the feat, was the conqueror of Hannibal at Zama. He was equally famous for his private virtues as for his military successes; and 'the continence of a Scipio,' a common phrase, had its origin in the refusal of Africanus to see a beautiful princess who had fallen into his hands, lest the frailty of human nature should tempt him to take any advantage of his power over her fate.  
 SCOTLAND, HISTORY OF—see History of Great Britain and Ireland, 129-176; description of, 225-240; superficial features, 225; geology, 225; hydrography, 226; climate, 227; botany and zoology, 227; population, 227; national industry, 228; remarkable scenery, 228; antiquities, 235; chief towns and ports, 236.  
 Scriptures, the authenticity of, 390.  
 SCULPTURE, 638-640.  
 Scylla, a rock off Sicily, famous as dangerous to mariners, in combination with the whirlpool Charybdis. The ancients called the rock a monster, into which the nymph Scylla had been changed by Circe.  
 Seasons, effects of on mortality, 551.  
 Second-sight, superstition of, 429.  
 Secretiveness, in Phrenology, 341.  
 Self, duty of trusting to one's, 473.  
 Self-esteem, sentiment of, in Phrenology, 342.  
 Self-help, duty of, 473.  
 Self-love, duty of, 451.  
 Self-respect, duty of, 459.  
 Semele, daughter of Cadmus, and mother of Bacchus by Jupiter, destroyed by her vain wish to behold her lover in all the insupportable blaze of his divinity.  
 Semiramis, a queen of Assyria, celebrated for her masculine strength of character, her warlike successes, and the magnificent buildings which she constructed in Babylon.  
 Semitic or Syro-Arabian race, in Ethnology, comprehends the Syrian and Arabian families of mankind, 2.  
 Sennefelder, inventor of Lithography, 730.  
 Sensations and organs of sense, 323.  
 September, festival Calendar for, 443.  
 Sequestration, law relating to, in Scotland, 502.  
 Serapis, a deity of the ancient Egyptians.  
 Serfs, serfdom, in feudal law, 56.  
 Serpent, musical instrument, 767.  
 Servants, in domestic economy, 771.  
 Servants and masters, respective duties of, 472.  
 Sesostrius, an early king, renowned for the extent of his conquests and the mildness of his sway.  
 Sestet, in Music, 765.  
 Shaving and shaving-pastes, 732.  
 Sheriff, jurisdiction and functions of, 45.  
 Shinty, hockey, or hurling, game of, 655.  
 Shrove-Tuesday, festival of, 434.  
 Sibyls, women inspired by the gods with the spirit of prophecy. The most famous of them was the Cumaean Sibyl, who is said to have resided at Cumæ in Italy, and to have obtained from Apollo the privilege of living for as many years as there were grains in a handful of sand. But she forgot to ask for youth also, and grew old and decrepit. It is stated that the Sibyl sold three of nine volumes of prophecies to the monarch Tarquin, and that these were preserved and consulted by the Romans with great reverence, until they were destroyed by fire. A book of Sibylline verses is extant, but scholars universally deem it spurious and modern. Every gypsy fortune-teller is familiarly termed a Sibyl.  
 Sight, as a sense, 326.  
 Sight, second, superstition of, 429.  
 Silenus, a son of Pan, and attendant of Bacchus, usually painted as a jolly intoxicated old man riding on an ass, and crowned with flowers.  
 Silks, how to keep and clean, 773.  
 Silver-plate, how to keep and clean, 773.  
 Similarity, the law of, in Metaphysics, 329; the emotion of, 333.  
 Sincerity and insincerity, duties regarding, 456.  
 Sinon, a Greek, whose frauds before Troy have made his name a byword.  
 Sirens.—Three sea-nymphs who lived on a small island near Sicily, and so charmed the passing voyager with their melodious voices, that he forgot all else, and died of starvation while listening. Ulysses, in order to hear them safely, had the ears of his crew stuffed, and himself tied to the mast of his ship. He was enchanted with the music, but the crew would not obey his commands to stop, and thus he listened and yet lived. The disappointed Sirens threw themselves into the sea. Fine female singers are styled Sirens in common speech.  
 Sisyphus, a crafty prince of the heroic times of Greece, who, for some uncertain offence to the gods, was doomed, in the infernal regions, to roll a huge stone up a hill, whence it re-descended immediately, rendering his punishment perpetual. The fruitless toil of Sisyphus is often the theme of allusion and comparison.  
 Size, organ of, in Phrenology, 348.  
 Skating, as an art and recreation, 648.  
 Sketching, in Drawing, 630.  
 Slander, crime of, 460.  
 Slavery, socially considered, 37.  
 Smell, as a sense, 324.  
 Smuggling or contraband trading, 502.  
 SOCIAL ECONOMICS OF THE INDUSTRIOUS ORDERS, 529-544.  
 Sociability, emotions of, 332.  
 SOCIETY, CONSTITUTION OF, 33-39.  
 Sociology, or the science of society, 368.  
 Socrates, the wisest and best character, perhaps, of antiquity. He was born and lived in Athens, where, in an unpretending way, he taught men to love virtue and cultivate knowledge. His opinions and actions, as recorded by his pupils Plato and Xenophon, have filled posterity with admiration for him from whom they came. Socrates was at length

- accused by the ungrateful Athenians of offences against religion, and died, according to his sentence, by drinking a cup of hemlock presented to him. His last moments, spent among his weeping friends, brought out his character in even a nobler light than it had before appeared in.
- Sol-fa-ing**, in musical practice, 742.
- Solon**, one of the seven wise men of Greece, celebrated for the equity of the laws dictated by him to the Athenians. His fame for wisdom has caused men of similar repute to be called Solons.
- Somnus**, the god of Sleep, and son of Night.
- Sophocles**, a tragic poet of Greece, who composed in a grave and lofty style.
- Soprano** (Ital. *sopra*, above), the upper or treble part in musical composition, 738.
- Spain and Portugal**, description of, 195.
- Spain under the Moors**, 119.
- Sparta**, history of, 89.
- Spectral illusions phrenologically treated**, 350.
- Spectres, spectral illusions**, 427.
- Speculation, game with cards**, 671.
- Spermaceti ointment, how to make**, 784.
- Sphinx**, a monster with the head and chest of a woman, a dog's body, a serpent's tail, and the wings of a bird, sent by Juno to devastate Bœotia. An oracle told that the Sphinx would destroy herself on one of her enigmas being explained, and Œdipus, on being asked by her what animal walked on four legs at morn, two at noon, and three in the evening, correctly answered 'man,' referring to infancy, manhood, and old age. The Sphinx then killed herself against a rock.
- Spruce-beer, recipe for making**, 780.
- Spurzheim, Dr, and Phrenology**, 357.
- St Agnes's Day, festival of**, 433.
- St Andrew's Day, festival of**, 446.
- St Crispian, festival of**, 443.
- St Christopher's or St Kitt's, island of**, 318.
- St David's Day, origin of**, 436.
- St Domingo, West India island, description of**, 320.
- St George's Day, in the Romish Calendar**, 439.
- St Lucia, West India Island**, 317.
- St Patrick's Day, origin of**, 436.
- St Swithin's Day, in the Romish Calendar**, 442.
- St Valentine's Day, origin of**, 435.
- St Vincent and its dependencies, West Indies**, 316.
- Stagyræ**, the birthplace of Aristotle; whence he was called the Stagyræite.
- Starching, how to practise**, 774.
- STATISTICS, POPULAR**, 545-560.
- Statute Law, in England**, 59.
- Steel-engraving, art and practice of**, 726.
- Steel-plate engraving, process of**, 728.
- Stentor**, a Greek, whose voice, according to Homer, equalled those of fifty men combined. 'Stentorian' is an established synonyme for excessively loud enunciation.
- Stereotyping, nature and process of**, 712.
- Stippling, a species of engraving**, 727.
- Stocks—Stock-Exchange—Stockjobbing**, 509.
- Stoics**, a sect of philosophers founded by Zeno, who professed so grave and stern a morality, that their designation has been applied to men who exhibit great powers of self-restraint and endurance.
- Stonehenge, temple of**, 215, 683.
- Stones, standing, in Archæology**, 688.
- Stuarts, the, reigns of**, 139-156.
- Style, in composition**, 689.
- Styx**, a cold and venomous river of the infernal regions, famous on account of the estimation in which it was held by the gods, who swore by it, and held such oaths inviolable.
- Subjects, public duties as**, 465.
- Subtraction, in Arithmetic**, 595; in Algebra, 605.
- SURFACES, 417-432.**
- Surds, or irrational quantities, in Algebra**, 606.
- Surveying of land**, 622.
- Suspensions, in Music**, 752.
- Swan River, British settlement of**, 284.
- Sweden, description of**, 206.
- Swimming as an art and recreation**, 647.
- Switzerland, description of**, 197.
- Sybaris**, a town on the bay of Tarentum in Italy, the inhabitants of which were so effeminate, that 'a Sybarite' has become a phrase applied to any person of such a character.
- Sympathy, in Metaphysics**, 335; in Phrenology, 352.
- Syntax, in English Grammar**, 537.
- Syria, ancient history of**, 73.
- Tacitus**, a Roman annalist of the Empire, whose writings have been deemed models of excellence in historical literature.
- Tailpieces, in Wood-Engraving**, 722.
- Talbotype or Calotype, art of**, 734.
- Tantalus, who, for murdering his own son, and serving him up to Jupiter to try his divine insight, was condemned to remain up to the neck in water, which ever fled from his lips as he sought to slake his perpetual thirst; hence the word 'tantalise,' now firmly fixed in various modern languages.**
- Tariff. See commercial terms**, 502.
- Tarpeia**, a woman who is said to have given name to the Tarpeian Rock on which stood the Capitol, and from which great malefactors were hurled by the Romans.
- Tarquinius, 99.**—From the son of the last Tarquin of Rome, forcible despoilers of female honour have gained a name appropriate to their actions.
- Tartarus**, the most familiar name of the infernal regions. Though taken often for the whole, Tartarus properly expressed the last abode of the wicked, as Elysium indicated that of the good.
- Taste, as a sense**, 324; faculty of, 352.
- Taxes, British, revenue arising from**, 183.
- Taxidermy, art of**, 781.
- Teeth, the, how to preserve and clean**, 783.
- Telemachus, son of Ulysses, who showed his filial piety by travelling in quest of his father, when the latter wandered from place to place on his way from Troy. Minerva accompanied the young prince under the form of an old man named Mentor; whence a common term for a counsellor and guide.**
- Tempé**, a vale of Thessaly, described by the poets as the most delightful spot on the earth, and used as a by-name for all similar scenes of natural beauty.
- Temperance drinks**, 780.
- Tennis, game of**, 655.
- Tenor or Tenóre (Ital.)**, the mean or middle part in musical composition, being the ordinary compass of the human voice when neither raised to a treble nor lowered to a bass, 738.
- Tenoroon, musical instrument**, 766.
- Terpsichoré**, the Muse of dancing, 87.
- Terror, emotion of**, 331.
- Testament, the Old, history of**, 385; the New, 388.
- Thales**, one of the seven wise men of Greece, peculiarly famous for his skill in astronomy.
- Thalia**, the Muse who presided over comic poetry, pastorals, and festival celebrations, 87.
- Themis**, a goddess whom Homer calls the presiding guardian of justice and civil law, and whom modern lawyers nominally acknowledge as their patroness. She is painted holding a sword and scales.
- Themistocles**, a famous Athenian commander, who conquered the Persians at the great naval fight of Salamis. Several anecdotes of him are often quoted. 'Strike, but hear me!' were words used by him to an angry adversary.
- Theocritus**, a native of Syracuse, styled the father of pastoral poetry.
- THERIOLOGY, NATURAL**, 369-384.
- Thermopylæ, famous battle of**, 91.
- Theseus**, an Athenian prince of the heroic age, renowned for his great deeds. In youth he went to Crete as one of the tributary band to be sacrificed in the Labyrinth to the Minotaur, but he slew the mon-

## INDEX, AND GLOSSARY OF TERMS.

- ster, and escaped by the help of the Clue of Ariadne. He afterwards deserted Ariadne. The share of Theseus in the battle of the Lapithæ, his friendship for Pirithous, proverbial for its closeness, and a visit to Tartarus, are among the principal other features in his story.
- Thespis, an ancient Greek poet, from whom, as the supposed inventor of tragedy, springs the phrase of the Thespian art, applied to the drama.
- Thetis, a sea-deity, who, by marriage with the mortal Peleus, became the mother of Achilles.
- Thiabé, a maiden of Babylon, beloved by Pyramus.
- Thor, the Scandinavian god of war, 418.
- Thucydides, a historian of Athens, highly esteemed for his fidelity and the merits of his style.
- Thule, an island in the northern parts of the German Ocean, termed by the Romans *Ultima Thule*, as the ultimate point of the earth in that direction. Some have thought it Greenland, and some Iceland; but the probability is, that the name was really applied to the Shetland Isles.
- Tiberius (Cæsar), successor of Augustus, and only less proverbial for cruelty than his successors Nero and Domitian.
- Tibullus, a poet of Rome, whose graceful and chaste compositions have gained for him a first place among elegiac bards.
- Time, duties regarding the use of, 451.
- Time, in Music, 739.
- Time, organ of, in Phrenology, 349.
- Timotheus, a poet and musician who followed the fortunes of Alexander, and is celebrated by Dryden as 'raising a mortal to the skies'—that is, flattering his master as a divinity.
- Tinting, in Drawing, 634.
- Tiresias, a famous Theban, struck blind, as the story runs, by Juno, but gifted with prophecy by Jupiter, and consulted during his life by all Greece.
- Tisiphone, one of the three Furies, 87.
- Titan.—The gigantic family of the Titans, descended from the Heaven and Earth, warred against Jupiter, and tossed mountains at him in their fury, but were subdued, and condemned to heavy punishments.
- Titania, queen of the fairies; 420.
- Titles and ranks, 48.
- Tobago, West India island, 316.
- Tone and semitone, in Music, 738.
- Torques, in Archæology, 684.
- Touch, as a sense, 325.
- Towers, round, in Archæology, 680.
- Trajan, a Roman emperor, whose many virtues are chiefly sullied by his cruelty to the primitive Christians of Rome. Trajan's Pillar at Rome is a work of great celebrity.
- Transition, enharmonic, in Music, 759.
- Trap-ball, game of, 655.
- Triangles, in Geometry, 612.
- Trigonometry, 622.
- Trinidad, island, account of, 316.
- Trio, in Music, 765.
- Triptolemus, a native of Eleusis, whom Ceres sought to make immortal by laying him upon flames to purge away the grossness of humanity; but his mother, through curiosity, peeped upon the proceedings, and, terrified at the sight, frustrated the design. In compensation, Ceres taught Triptolemus the art of agriculture, and gave him the honour of its dissemination over the earth.
- Triton, a leading sea-god, represented as half man half dolphin; and always seen blowing a horn.
- Trombone or Sackbut, musical instrument, 767.
- Trosachs, scenery of, 228.
- Trumpet, musical instrument, 767.
- Truth and falsehood, duties regarding, 455.
- Tumuli, in Archæology, 679.
- Tune, organ of, in Phrenology, 349.
- Turkey in Europe, description of, 199; in Asia, 258.
- Turks during the Middle Ages, 125.
- Tusculum, the country-seat of Cicero, from which similar retreats of renowned men are sometimes called Tusculan villas.
- Types, used in printing, 709.
- Tyrteus, a Greek poet, usually held the type of martial verse-writers.
- Ulysses, king of Ithaca, usually deemed the wisest of the Greeks who went to Troy. After the close of the siege of that city, during which he carried off its Palladium, and performed many feats of address and valour, he underwent many years of adventure, described in the 'Odyssey,' ere he reached his home. There he found his means wasted by suitors for his wife Penelope; but the tried warrior soon slew or dispersed them all, and resumed his throne in peace.
- United States, general account of, 298-304.
- Universities of Great Britain and Ireland, 181; university towns, 222.
- Urania, the Muse who presided over astronomy, 87.
- Utopia, Utopian communities, 34.
- Van Diemen's Land, colony of, 285.
- Vanity, duty regarding, 460.
- Vassals, vassalage in feudal law, 54.
- Vaulting, in Gymnastics, 642.
- Vegetable Physiology, design in, 381.
- Vendue. See commercial terms, 602.
- Veneration, in Metaphysics, 352; in Phrenology, 345.
- Venezuela, Republic of, described, 307.
- Ventilation, duties regarding, 451.
- Ventilation and fumigation, 776.
- Venus, the goddess of Love and Beauty, and mother of Cupid. Her parentage is not settled; but she sprung directly, it is said, from the froth of the sea, and was immediately received among the deities. The character given to Venus is one befitting only the goddess of licentious pleasure. Her power to charm is stated to have depended on her *castus* or zone, and she was usually represented sitting in a chariot drawn by doves. From various favourite spots she is called by the names of the Cytherean, Cyprian, and Paphian goddess, as well as by other names, 87.
- Verb, in Grammar, 579; inflection of, 583.
- Vermin, how to destroy, 774.
- Vertumnus, the god of Spring among the Romans.
- Vesta, usually termed the mother of the deities, and patroness of the virgins called Vestal, who, like modern sisterhoods of nuns, retired from the world to live in sacred establishments. Any departure from chastity was fearfully punished in them, and to seduce a Vestal Virgin was deemed a horrible crime in men. A fire was kept burning continually in the vestal establishments, its extinction being dreaded as an omen of heavy calamity. The phrases of 'Vestal Virgins' and 'vestal flames' are familiarly used in the sense here indicated.
- Violin, viola, and violoncello, in Music, 765.
- Virgin islands, West Indies, 318.
- Virginia, daughter of the tribune Virginius, having arrested the licentious eye of Appius Claudius, then in power, he endeavoured to get possession of her by proving her to be his slave; but her father defeated his nearly successful design by stabbing her with his own hands, to preserve her honour.
- Voice, the human, as fitted for articulate sounds, 18.
- Voices, in choral harmony, 765.
- Vowels, and vowel sounds, in Language, 18.
- Vulcan, son of Juno, and god of Fire, supposed to work, with his assistants the Cyclops, in the interior of Mount Ætna. Though lame and deformed, he was the husband of the goddess of Beauty, and father of Cupid. He acted as armourer to the gods, and sometimes wrought for men, as in the case of Achilles. The worship of Vulcan was well established, 87.
- Vulgarity, what it is, 458.
- Wages, in Political Economy, 489.
- Wales, New South, account of, 263.
- Walhalla, or Valhalla, in Scandinavian mythology

CHAMBERS'S INFORMATION FOR THE PEOPLE.

- the great hall for the reception of the spirits of the brave, 418.  
 Walking, in Gymnastics, 644-647.  
 Walls, how to keep and clean, 772.  
 Wassail bowl, origin of the term, 433.  
 Water, how to manage in household economy; how to purify; how to filter; how to test, 779.  
 Weight, organ of, in Phrenology, 348.  
 Weights and measures, British, 597.  
 Wellington, military successes of, 170-173.  
 Whist, game of, 667.  
 Whitsunday, term and festival of, 441.  
 Wife and husband, respective relations of, 470.  
 Wight, Isle of, described, 215.  
 Wilkes, Mr John, 161.  
 Will, duty of making a, 473.  
 Will, the human, 336.  
 Windows, how to keep and clean, 772.  
 Wit, in Metaphysics, 333; in Phrenology, 347; in literary compositions, 692.  
 Witchcraft, account of, 421-427.  
 Wonder, organ of, in Phrenology, 346.  
 Wood-engraving, practice of as an art, 721-724; as a profession, 725.  
 Words, formation of, 18.
- Xanthus, the ancient capital of Lydia, whence the Xanthian marbles now in the British Museum.  
 Xantippé, wife of Socrates, and so great a shrew as to have given a name to all ladies similarly gifted.  
 Xenophon, an illustrious writer and soldier of Athens, who went to Persia to assist Cyrus to obtain the throne of that country. When Cyrus was defeated, the auxiliary Greeks made that retreat homewards so often adverted to as the Retreat of the Ten Thousand. Xenophon latterly was their leader.  
 Xylography (Gr. *xylon*, wood, and *graphain*, to draw), an affected term for the art of wood-engraving; hence also xylograph, 721.
- Yankee, a familiar epithet for a native of the United States of America; thought to be a corrupt pronunciation, by the native Indians, of the French word *Anglais*.  
 York, House of, in English history, 133; city of, 224.  
 Youth, duties of, 449.  
 Yucatan, state of, described, 304.  
 Yule (from the same root as the Greek word *helios*, the sun), the name given in Scotland to Christmas; originally the great annual feast among northern nations at the time of the winter solstice, in honour of the sun.
- Zealand, New, settlements of, 286.  
 Zemindar, a Hindoostanee term for a feudatory or landholder who governs a district of country, and collects taxes, either directly or through others who farm them from him.  
 Zendavesta, the sacred book of the Parsees, ascribed to Zoroaster, and held as the sole rule of faith and practice; Zend, the term applied to the language in which the book is written.  
 Zincography, a species of engraving, 732.  
 Zoophytes, design in the structure of, 373.  
 Zoroaster, a famous Persian sage, who is said to have founded or reformed the religion of the Magi.

THE END.

## INDEX, AND GLOSSARY OF TERMS.

- security for the return of the other. Damon returned, even to his friend's regret. The scene betwixt them was so moving that it led to a pardon.—Damon is a common name for a swain, being much used in the old pastorals.
- Danaë**, the daughter of a king of Argos, was shut up in a tower because it was foretold that a son of hers should kill his grandfather. The god Jupiter, however, introduced himself in the form of a golden shower, and Danaë bore to him Perseus, with whom she was exposed at sea in a slight bark, and who afterwards accidentally killed his grandfather with a quoit.
- Danaides**, the fifty daughters of King Danaus, who, to prevent the fulfilment of an oracle of fatal import, caused them to murder their husbands. All obeyed but one; and, for the crime, they were condemned perpetually to the fruitless task of filling a sieve with water in the infernal regions.
- Dancing**, as an amusement, 671.
- Daphné**, a nymph, who, when flying from the enamoured pursuit of Apollo, was converted into the laurel-tree.
- Daric**, a Persian gold coin of about 130 grains; so called from Darius, the name of several of the Persian kings: there were also silver Darics.
- Deacon** (Gr. *deaconos*, a servant), one of the orders of the Christian church, to whom originally the administration of charity was committed; an assistant or servant to the priest or minister, 396.
- Deaths**, statistics of, 549.
- Debenture** (Lat. *debeo*, I owe), in Commerce, 502.
- December**, festival Calendar for, 447.
- Definitions**, importance of, in Logic, 358.
- Delegate** (Lat. *delego*, I choose from), one chosen, and sent by another to act as his representative; a deputy.
- Delphi** (now Castri), a town of Phocis, situated on the side of Mount Parnassus. The place was especially sacred to Apollo, both as the god of Poetry and Divination, and here stood the most famous of the Greek temples and oracles, 88.
- Delphin**.—In bibliography, a term applied to the edition of the Latin classics, prepared and commented upon by thirty-nine of the most famous scholars of the day, at the suggestion of Louis XIV., king of France, for the use of his young son the dauphin (in *usum Delphini*), under the direction of his governor Montausier, and his preceptors Bossuet and Huet.
- Democracy** (Gr. *demos*, the people, and *kratio*, I govern).—That form of government in which the whole or majority of the adult population have a voice in the election of their rulers or representatives.
- Democritus**, a personage called the Laughing Philosopher, from his deeming it better to smile than to weep at the follies of mankind.
- Demonology**. See Superstitions, 417–432.
- Demosthenes**, the greatest of the ancient orators.—An Athenian by birth, he was early seized with an ardent desire to excel in speaking; and though he had many natural disadvantages to contend with, he overcame them all. He cured a habit of stammering by placing pebbles in his mouth; he inured himself to the turbulence of a popular auditory by speaking on the sea-shore during storms; and he removed the distortions of his visage by delivery before a mirror. He shut himself up, moreover, to indulge in study; and over the midnight lamp were composed those sublime orations which yet remain without parallel, and by which he wielded at will the fierce democracy of Athens. His greatest efforts, when he had raised himself to power, were directed against Philip of Macedon; and from the title given to his harangues on this subject, similar attacks are yet commonly termed Philippics. The Macedonians ultimately triumphed, however, and Demosthenes escaped from his enemies by taking poison in the sixtieth year of his age.
- Denmark**, description of, 205.
- Depilatories** (Lat. *pilus*, the hair), composition of, 784.
- Derby**, town of, 219; Derbyshire scenery, 214.
- Derivation of words**, in Grammar, 586.
- Dervise** (Persian, *poor*), a term applied to certain Asiatic fanatics, who, like the monks of Christendom, either live in a body solitarily as hermits, or wander about as mendicants.
- Desires of the human mind**, 334.
- Despotisms**, despotic government, 41.
- Destructiveness**, in Phrenology, 341.
- Deucalion**, a prince of Thessaly, who, with his wife Pyrrha, escaped, by means of a ship, from a great deluge said to have occurred in their time. The vessel rested on Parnassus, and Deucalion, directed by an oracle how to repeople the earth, threw stones over his shoulder, which instantly became men. Pyrrha did the same, and women were formed.
- Diana**, sister of Apollo, goddess of hunting, and in heaven called Luna, or the Moon. She was represented in the garb of a quivered huntress followed by dogs, and was a renowned patroness of maiden chastity, though she is said to have fallen in love with Endymion, a young man of Latmos, as he lay asleep, and even to have wedded him. She had eighty nymphs who attended her in the chase. The most famous temple of Diana was that at Ephesus, called one of the seven earthly wonders, and set fire to by one who sought thereby to gain an immortal name. Diana is often called Cynthia, or Delia, from the place of her birth; and in the character of the moon, is usually termed Phoebe, 87.
- Dido**, a Phœnician princess, who founded Carthage, and while it existed, was worshipped in that city. Æneas, after wooing Dido, deserted her, and her memory has become associated with the idea of a forlorn woman.
- Digit** (Gr. *digitos*, a finger), in mensuration, a finger's breadth =  $\frac{1}{2}$  of an inch; in arithmetic, the numerals under 10; in astronomy, the twelfth part of the diameter of the sun or moon, employed in measuring the extent of an eclipse.
- Dilletante** (Ital.), an admirer of the fine arts; one who delights to promote the sciences or the fine arts.
- Diogenes**, the type of all sour, snarling philosophers. He was of the Cynic sect, and so despised luxury as to live in a tub. Many of his sayings are frequently quoted; as, for example, his answer to Alexander the Great, when that prince asked him what he could do to oblige him. 'Stand away from betwixt me and the sun,' said Diogenes.
- Dionysius** (the elder), tyrant of Sicily, who, amongst other characteristic deeds, constructed a cave commonly called 'The Ear of Dionysius,' which was of such a form that every word uttered by his prisoners in an adjoining prison could be heard by him.—Dionysius, son and successor of the preceding, and so apt an imitator of his cruel practices, that he was finally driven from his throne, and, to earn his bread, was compelled to teach a school at Corinth, whence fallen despots are often compared to him.
- Diploma** (Gr.), a document on paper or parchment, conferring power, authority, privilege, or honour. Surgeons, clergymen, and other professional parties, receive diplomas from their respective faculties.
- Diplomacy**, from the same root, refers to the customs, rules, privileges, and forms of negotiation between state and state, as observed by their respective agents.
- Diplomacy**, international, nature of, 45.
- Diseases**, statistics of, 550.
- Dispensary**, the Provident, 542.
- Distemper**, in ordinary language, a diseased or morbid state of an animal body; an undue or unnatural temper of mind. In painting, the mixing of colours with something besides oil or water.
- Distribution**, in Political Economy, 489.
- Division**, in Arithmetic, 596; in Algebra, 605.
- Dodona**, a town of Epirus, and the site of an oracle of Jupiter, whose responses were frequently delivered by or among the sacred oaks of the neighbourhood.

Domestic relations and duties, 469.  
 Dominica, island of, 317.  
 Domitian, a Roman emperor, proverbial for his cruelty.  
 Draco, a lawgiver of Athens, whose statutes were so severe, that it was said they were written in blood.  
 Harsh edicts are often compared to them.  
 Drama, the nature of, 708.  
 Draughts, game of, 661.  
 DRAWING, 625-638.  
 Dreams, superstitious belief in, 430.  
 Druidical temples, 215, 683.  
 Dryades, nymphs fabled to preside over the woods, 87.  
 Dublin, description and account of, 248.  
 Duenna (Span.), the name given to the chief lady-in-waiting upon the queen of Spain; generally familiarly applied to ladies who attend others in a capacity somewhat between a governess and companion.  
 Dulcimer (Lat. *dulce*, sweet), 768.  
 Dundee, description and account of, 239.  
 Duns, in Archaeology, 679.  
 DUTIES OF LIFE, PRIVATE, 449-464; PUBLIC AND SOCIAL, 465-480.  
 Earl, a British title of nobility, 48.  
 Earth, design in the structure of, 373.  
 Earthenware and china, in house-furnishing, 770; how to mend, 780.  
 Easel, the frame on which painters place their canvas.  
 Easter, in the Romish calendar, 439.  
 Echo, a nymph whose powers of speech, as a punishment for prating, were limited to the answering of questions. Falling afterwards in love with Narcissus, that youth's cruelty caused her to pine away, and she was changed to a stone, which still retains the power of speech.  
 ECONOMICS, SOCIAL, 529-544.  
 ECONOMY, POLITICAL, 481-496.  
 Ecuador or Equator, republic of, 308.  
 Edinburgh, description and account of, 236.  
 EDUCATION, AS A SCIENCE, 561-576; statistics of, 557; physical education, 561; moral, 562; intellectual, 568; industrial, 575; mechanism for education, 573; in England, 181; in Ireland, 181; in Scotland, 182.  
 Egeria, a nymph or deity, from whom Numa, king of Rome, pretended to receive counsel in secret on affairs of state.  
 Egypt and Egyptians, ancient, 71; modern, 275; antiquities, 673; pyramids, 674; hieroglyphics, 676.  
 Electors, our duties as, 467.  
 Eleusis, a city of Attica, the chief scene of the celebration of the Eleusinian Mysteries, 87.  
 Elizabeth, government and character of, 137.  
 Elysium, the happy seat of the departed spirits of the good, according to the Greeks and Romans, 88.  
 Emotions, of the human mind, 331.  
 Empedocles, a man of superior talents, who, wishing to be deemed a god, leapt into the crater of *Ætna*, thinking that he might so conceal his having been subject to death like common mortals. But his sandal was thrown up, and frustrated his insane ambition.  
 Emporium (Lat.), originally and properly the town in which the trade and commerce of a district centres; now applied to any place of merchandise. In pathology, the common sensory of the brain.  
 Emulation, duties regarding, 462.  
 Endymion, a youth of Latmos, beloved of the moon; in frequent use by the poets.  
 ENGLAND, HISTORY OF, see History of Great Britain and Ireland, 129-176; description of, 209-224; superficial features, 209; geology, 209; hydrography, 210; climate, 211; botany and zoology, 210; population, 212; national industry, 215; government, 213; scenery, 214; antiquities, 215; cities and towns, 216; church of, 180.  
 ENGRAVING, 721-731; on wood, 721; on steel and copper, 726; on gems and seals, 730.  
 Enharmonic transition, in Music, 759.  
 Envy, crime of, 462.

Epaminondas, a Theban chief, one of the most noble characters in Grecian history. A great and victorious soldier, he was even more conspicuous for virtue, wisdom, temperance, and patriotism.  
 Epic poetry, nature of, 702.  
 Epicurus, a celebrated philosopher of Attican descent, whose name has most unfairly become a synonyme for a sensualist of a gross kind. His philosophy was certainly based on the maxim that 'Pleasure is the highest good;' but Epicurus well knew, and ever taught, that moderation in the gratification of the senses is the sole means of attaining to true and lasting pleasure; and that a 'happy life' rests fundamentally on health of body and tranquillity of mind, possessions never to be won or preserved by excessive sensual indulgence. What propriety is there in a word of such etymology as the word 'epicure,' when the daily diet of the man whose name is so abused consisted of 'barley-cake and water from the spring!'  
 Epigram.—This term (Gr. *epigramma*) originally merely signified an inscription, and from this use the poetry so called derived its prevailing character. The Greek epigram served alike for mottoes, mementos, panegyrics, or epitaphs; now the epigram is expected to possess a certain smartness of manner and sharpness of point and wit, 691.  
 Epiphany, festival of, 433.  
 Equations, in Algebra, 607.  
 Equity, law of, in England, 58.  
 Erato, the Muse who presided over amorous verse.  
 Erëbus, an infernal deity, whose name is often used to signify the supposed place of his abode.  
 Erotic (Gr. *erōs*, the principle of love), a term applied to certain kinds of amatory songs or poems.  
 Esoteric (Gr. private), an epithet applied to the private instructions and doctrines of Pythagoras—*esoteric* being the term applied to such as were openly professed and taught.  
 Etching on copper, 726; on steel, 728; on glass, 729; on stone, 732.  
 ETHICS—MORAL PHILOSOPHY, 383.  
 Ethiopic or African variety of mankind, physical and mental characteristics of, 4; history of, 65.  
 ETHNOLOGY, 1-16.  
 Etymology, in English Grammar, 577.  
 Euclid, analysis of his 'Elements,' 617-624.  
 Euripides, a Greek poet, whose tragedies are marked by great tenderness and elegance.  
 Europa, a beautiful woman, to whom the enamoured Jupiter appeared in the form of a bull, and when she thoughtlessly mounted on the back of the supposed animal, carried her off. She gave name, it is further fabled, to the European continent.  
 EUROPE, GENERAL DESCRIPTION OF, 193-208.  
 Eurydice, wife of the poet and musician Orpheus. When she died from the bite of a serpent, Orpheus was so deeply grieved that he ventured to seek her among the shades; and having, by his music, drawn 'iron tears down Pluto's cheek,' was permitted by the infernal chief to take his wife back to earth, on condition that he did not turn to look on her till his arrival there. He violated the condition, and lost her for ever.  
 Evangelists, the four, 388.  
 Eventuality, organ of, in Phrenology, 349.  
 Evils, our duty regarding, 474.  
 Exchange, in Political Economy, 487.  
 Excise duties, in Commerce, 502.  
 Exoteric. See Esoteric.  
 Exports and imports of Britain, 187.  
 Extravaganza (Ital.): in music, any composition remarkable for its incoherence and wildness.  
 Fabius, the name of a noble Roman house, the most illustrious member of which was Quintus Fabius Maximus. The alarming successes of the Carthaginian, Hannibal, who defeated in succession all who came against him, received a notable check when

## INDEX, AND GLOSSARY OF TERMS.

- Fabius** took the command of the Roman army. His policy was not to fight, but to wear out Hannibal, then in a hostile country; and from this circumstance Fabius received at the time the name of *Cunctator*, 'The Delayer or Hesitator.' Ever since that age, every cautious commander has been called a follower of the Fabian policy.
- Fairies**, account of the, 420.
- Falkland Islands**, settlement of, 313.
- Fallacies**, in Logic, 363.
- Falsehood and truth**, duties regarding, 455.
- Falsetto** (Ital.): a musical term, signifying a false voice or artificial manner of singing, produced by tightening the ligaments of the glottis, and thus extending the vocal compass about an octave higher. The natural voice, or voice from the chest, is termed *vox di petto*.
- Farøe Islands**. See Denmark, 205.
- Fathers**, the Christian, 397.
- Faunalia**. See Lupercalia.
- Fauns**.—The Fauns were minor rural deities, painted as having the form of goats from the middle downwards, with the horns and ears of the same animals.
- Faust or Faustus**, his connection with the invention of printing, 705-706.
- February**, festival Calendar for, 434.
- Feet**, the, in personal economy, 784.
- Female sex**, honour to, 457.
- Fetishiam**, account of, 401.
- Feudal system**, origin of, 116.
- Fiddle or violin**, in Music, 765.
- Fief** (Fr.), in feudal law the name for an estate in lands held off a superior, 54.
- Fife**, musical instrument, 766.
- Filters**, for water, 778.
- Fire**, escapes from, 775; how to light, 776.
- Firmness**, sentiment of, in Phrenology, 345.
- Firms**. See commercial terms, 499.
- Fishes**, design in the structure of, 375.
- Fitness**, emotion of, in Metaphysics, 333.
- Flageolet**, musical instrument, 766.
- Flies**, how to destroy, in Household Economy, 775.
- Floors**, wooden, how to clean, 771.
- Flora**, a goddess of the Roman Pantheon, who presided over flowers, gardens, orchards, and vineyards, and was usually painted as crowned with flowers, and holding the horn of plenty. She married Zephyrus, the god of the west wind, and received from him the privilege of immortal youth.
- Florin** (Fr.), a name given to different silver coins current in several continental countries, especially in Germany and Austria; the name also given to the two-shilling piece recently coined in Britain. In Austria, the florin is equal to 2s. 0½d.; in Holland and Western Germany, 1s. 8d.; in Poland, 6d.; and the Rhenish gold florin is equal to 6s. 11d.
- Flowers**, how to preserve fresh, 782.
- Flute**, musical instrument, 766.
- Folio** (Lat.), a printer and bookbinder's term, 711.
- Food**, duties regarding, 460.
- Foot-ball**, game of, 655.
- Form**, organ of, in Phrenology, 347.
- Forta**, venerated, in Archeology, 679.
- Forum**, the market-place, and also the seat of a pre-terorian court of justice in the Roman cities. The word is now applied to courts of justice, whence the phrase of 'forensic' or legal oratory.
- Fount**, an assortment of types, in Printing, 709.
- Fractions**, in Arithmetic, 599; in Algebra, 606.
- France**, description of, 193.
- French-horn or Corno**, in Music, 767.
- Friendly societies**, 533-536.
- Fugue**, in musical composition, 764.
- Fumigation and ventilation**, 776.
- Funds**, minor economic, 544.
- Furies**, the three Furies, named *Alecto*, *Megera*, and *Tisiphone*. These sisters were supposed to be the ministers of Divine vengeance, punishing mortals on earth both with external evils and the stings of con-
- science, and inflicting continued torments on the bad in the infernal regions, 87.
- Furniture and house-furnishing**, 769; how to clean, 773.
- Galatea**, a sea-nymph, in love with Acis, whom Polyphemus the Cyclop killed through jealousy.
- Gall**, founder of phrenology, 337.
- Ganymedes**, a beautiful Phrygian youth, carried away by Jupiter to be the cup-bearer of the gods in place of Hêbé. An eagle conveyed him, and he is usually pictured on the back of that bird.
- Gauls**, invasion of Rome by, 99.
- Gentility**, what it is, 458.
- GEOMETRY, PLANE**, 609-624; solid, 620; spherical, 622; logic of, 336.
- Germanic family**, characteristics of, 2.
- Germany**, geographical description of, 202.
- Geryon**, a monstrous being with three heads, slain by Hercules.
- Ginger-beer**, recipe for, 780.
- Gladiatorii Ludi**.—Gladiatorial sports, so called from *gladius* (a sword), were exhibitions at which slaves, captives, and trained fighters, butchered one another for the amusement of the people of Rome.
- Glasgow**, description and account of, 237.
- Glass and crystal**, in house-furnishing, 770; how to cut, 780.
- Glyphography**, art of, 729.
- Gnome** (Gr. *gnomon*, an interpreter): an imaginary being, supposed to inhabit the inner parts of the earth. The Gnomes are represented as of small stature, and are supposed to be the guardians of mines, caverns, &c.
- Golf**, ancient game of, 653.
- Good-Friday**, festival of, 437.
- Gordius**, a Phrygian peasant, who, when his countrymen were told by the oracle to enthrone the first man whom they met going to the temple of Jupiter in a car, had the good fortune to be found in that situation. Immediately afterwards, he consecrated his car in the temple, tying the yoke to the draught with such art that it could not be unloosed. Then the report spread that the oracle had decreed the empire of Asia to him who should untie the Gordian Knot. Coming to the place, Alexander the Great made short work of the difficulty by cutting the cord with his sword, and thereupon he claimed to be the foretold ruler of Asia.
- Gorgon**, a name specially applied to Medusa, one of three sisters who had wings of gold, and but one eye for use among the three. The 'Gorgon's head,' or 'Medusa's head,' is frequently alluded to as significant of an object of terror, because it was encircled with snakes, and turned the beholder to stone.
- GOVERNMENT, VARIOUS FORMS OF**, 40-46.
- Gracchus**, the name of a noble family of republican Rome, two members of which made themselves noted for their revolutionary measures, 104.
- GRAMMAR, UNIVERSAL**, 21-25; **ENGLISH**, 577-592.
- Grates**, for houses, 769.
- Gratitude and ingratitude**, duties regarding, 460.
- Grease spots**, how to remove, 774.
- GREECE, ANCIENT HISTORY OF**, 81-96; mythology of, 81; religious rites of, 86; literature and fine arts of, 95, 96; Modern Greece, description of, 200.
- Greenland**, general description of, 297.
- Grenada**, new republic of, 308; island of, 316.
- Guiana**, territory of, described, 812.
- Guillotine**, instrument of execution, 687.
- Guitar**, musical instrument, 768.
- Gules** (red), a term in heraldry, 47.
- Gunpowder plot**, in English history, 141, 446.
- Gutenberg**, the father of printing, 705.
- GYMNASTIC EXERCISES**, 641-647.
- Habeas-Corpus Act**, 149.
- Habeas Corpus**, in Law, 62.
- Habits**, duties respecting the formation of, 453.
- Habits**, metaphysically considered, 334, 352.

Hair, how to keep and preserve, 784.

Hair-dyes, 784.

Halcyoné, a princess who grieved so deeply for the loss of her spouse at sea, that she was sent to that element out of pity, changed into a kingfisher. Being favoured with seven calm days for brooding, the phrase of 'Halcyon days' came to denote a time of peaceful happiness.

Hallowe'en—All-Hallow eve, festival of, 444.

Hamadryades, rural nymphs, who are said to preside over trees.

Handsel-Monday, first Monday of the year, 448.

Hannibal, a famous Carthaginian, who, when a boy, was made by his father to vow eternal enmity to Rome. He fulfilled in due time the oath, proving the most dangerous foe ever known to the Romans. So great was the promise of his early days, that before the age of twenty-six he received the command-in-chief of all the armies of his country. In this situation he determined upon the bold step of crossing the Alps, and carrying war into the heart of Italy. His passage has ever been viewed as a wonderful military feat, and was partly accomplished, historians say, by his kindling large fires, and pouring vinegar on the heated rocks, which caused them to rend or crumble in pieces. Once in Italy, he defeated, one after another, all the commanders sent against him from Rome, and for sixteen years held that city in continuous alarm. At length the Romans sent a force to menace Carthage, and Hannibal was hastily recalled, only to be wholly vanquished near his native city by Scipio Africanus. A brief peace was granted afterwards to Carthage; but mistrustful of his enemies, Hannibal fled to Syria, and subsequently to Bithynia, where, his person being demanded by the Romans, he ended his life by taking poison, 182 B.C. The youthful vow and acts of Hannibal meet with frequent notice in literature, 102.

Happiness, attainment of, 464.

Hardware and cutlery, in domestic economy, 770.

Harmonium, musical instrument, 768.

Harmony, in Metaphysics, 333.

Harmony, nature of, in Music, 737, 744.

Harp, stringed musical instrument, 768.

Harpichord, musical instrument, 768.

Hautboy or Oboe, musical instrument, 766.

Health, duties regarding, 450.

Hearing, as a sense, 325.

Hèbè, daughter of Jupiter and Juno, and the goddess of youth, for which, in its beautiful forms, her name is a synonyme. She was the first cup-bearer of the gods.

Hebrides or Western Islands of Scotland, 235.

Hecate, the goddess supposed to preside over enchantments.

Hector, the most valiant of the sons of King Priam of Troy, ultimately killed by Achilles. His name is applied to brave men, and not unfrequently to boastful ones, though Homer assigns none but truly great qualities to the Trojan prince.

Hejira or Hegira, era of, 411.

Helena, the most beautiful woman of her age, and whose abduction from her husband, Menelaus, king of Sparta, by the Trojan prince Paris, caused the siege and fall of Troy, all the Greek princes having united to effect her recovery. Helen was one of the children of Leda by Jupiter. She was ultimately restored to Menelaus.

Helicon, a mountain of Bœotia, sacred to the Muses, who had a temple there.

Heliogabalus, a Roman emperor, so extravagantly devoted to the pleasures of the table, that his name has become a synonyme for a glutton.

Heliography or sun-drawing, 732.

Helots, a menial caste at Sparta, whose name has become significant of the most abject slavery, 90.

HERALDRY, 46-48.

Hercules, the most famous personage of the heroic age

of Greece. He is the type of physical power in painting and sculpture, and is always drawn with a mighty club in his hand, 82.

Hero, a fair priestess of Venus, who, when her lover Leander perished in swimming across the Hellespont, threw herself into the sea. She is often painted with a torch in her hand, as a guide to the bold but unfortunate swimmer.

Herodotus, a famed historian of Greece, generally styled the 'father of history.'

Hesiod, a very early Bœotian poet of superior powers.

Hesperides, three celebrated nymphs, who, with a dragon for a watchdog, were intrusted with the care of Juno's golden apples, placed in a garden in the neighbourhood, it was said, of Mount Atlas. Hercules, in one of his labours, carried off some of this much-prized fruit. This story of the apples of the Hesperides is often used, by way of comparison, to signify things of difficult access and great rarity and price.

Hieroglyphics, Egyptian, 675.

Hindooism, account of, 70, 268, and 403.

Hindoostan or India, Ancient, history of, 69; castes and population of, 69; antiquities of, 677; Vedas, the, or ancient sacred books of the Hindoos, 70—Modern, description and account of, 261-272; territorial division, 262; civil history, 263; revenue system of British India, 265; native populations, 267; religion, 268; products, 269; chief cities, 271.

Hippocrates, a physician of the isle of Cos, whose existing writings prove him to have made wonderful advances, for his time, in the art of medicine, and whose name is yet often alluded to.

Hippocrene, a fountain on Mount Helicon, the waters of which are said to have given inspiration to poets, because the hill was sacred to the Muses.

HISTORY OF ANCIENT NATIONS, 65-80; OF GREECE, 81-96; OF ROME, 97-112; OF THE MIDDLE AGES, 113-128; OF GREAT BRITAIN AND IRELAND, 129-176.

History, as a literary art, 695.

Hockey or shinty, game of, 655.

Hogmanay, in Scotland, last day of the year, 448.

Holland, geographical description of, 203.

Holograph (Gr. *holos*, whole, and *grapho*, I write), a law-term for a will entirely written by the hand of the testator.

Homer, the greatest of the poets of Greece, born, according to the most probable accounts, in the isle of Chios. His name signifies 'The Blind,' and he is said not only to have suffered under this calamity, but to have been a mendicant, or at least a wanderer dependent on his minstrelsy for daily bread. The combination of all the highest poetical qualities in the writings of Homer, from terrible sublimity to the tenderest pathos, has been a fruitful source of astonishment to succeeding times, the rudeness of the age in which he lived being considered. The 'Iliad' and the 'Odyssey' are his great works.

Honduras or Belize, account of, 297.

Hope, faculty of, in Phrenology, 346.

Horace, a Roman poet, whose lyrics and satires abound in maxims which are often and deservedly quoted.

Hortus siccus, how to form, 781.

House, choice and furnishing of, 769; order and management, 770; cleaning, 771; ventilation, &c. 776.

HOUSEHOLD HINTS, 769-784.

Housekeeping, economy of, 770.

Hull, sea-port, description of, 221.

Humour, in style, 692.

Hurling or shinty, game of, 655.

Husband and wife, relation of, 470.

Hybla, a mount of Sicily, famous for its fragrant thyme and its honey.

Hydra, a many-headed monster killed by Hercules, to which an unruly rabble is often compared.

Hygeia, the goddess of health, daughter of Æsculapius.

Hymen (or *Hymenæus*), the god of marriage, whose favour was solemnly invoked with song and sacrifice by all entering on the wedded state.

INDEX, AND GLOSSARY OF TERMS.

Iambics, verses composed of short and long syllables alternately.

Icárus, son of Dædalus, who, in flying from Crete with his sire, soared so near the sun as to melt the joints of the wings made by his father, and thereby fell into the sea.

Iceland, description of, 215.

Iconoclastm (Gr. *eikon*, an image, and *klasma*, a breaking), the act of breaking or destroying images or statues; Iconoclast, one who destroys images.

Iconography, a description of statues and similar monuments of ancient art.

Ida, a mountain near Troy, where Paris assigned to Venus the prize of beauty over Juno and Minerva.

Idealism, in metaphysics, the system or theory that makes everything to consist in ideas, and denies the existence of material bodies; also the designation of many and different systems of philosophy, which only agree in the common principle from which they originate. This principle is the opposite of the ideal and the real—that is, of ideas and things; the contrariety of mind and body, or of spirit and matter. An Idealist is one who holds the doctrines of idealism.

Ideality, organ of, in Phrenology, 346.

Idiom, a mode of speaking peculiar to a language or dialect; hence we speak Latinisms, Gallicisms, Scotticisms, &c.

Ilissus, a river and river-god of Attica, remarkable as the subject of a noble extant piece of Greek statuary.

Ilium, a name for Troy; whence the term *Iliad*.

Illusions, spectral, 427.

Imbroglío (Ital.): in literature, the plot of a romance or drama, when much perplexed or complicated, is said to be an *imbroglío*.

Imitation, in Metaphysics, 335; in Phrenology, 347; in musical composition, 764.

Imports and exports of Britain, 187.

Imprint, in letterpress-printing, the designation of the place where, by whom, and when, a book is published. Among the early printers it was inserted at the end of the book, and was styled a *colophon*.

Incombustible cloth, how to make, 780.

INDIES, EAST. See Hindoostan, 261-272.

INDIES, WEST, general account of, 313-320.

Individuality, in Phrenology, 347.

Indorse (Lat. *in*, and *dorsum*, the back), to write on the back of a paper or written instrument; hence to assign or transfer a bill, for example, by indorsement. Indorsee, the person to whom a bill or note is indorsed, or assigned by indorsement.

Induction, in Logic, 359.

Industry, nature of, in Political Economy, 498.

Infancy, management of, 449.

Inflection of words, in Grammar, 581.

Inhabitiveness, in Phrenology, 340.

Ink-stains, how to remove, 773-774.

Inks, sympathetic, 780; indelible, 781; common, 781.

Insects, design in the structure of, 374; how to preserve, 781.

Insignia (Lat.), a term applied to badges, or distinguished marks of office or honour.

Instincts of the human mind, 327.

Intellect, the human, 328.

Intemperance, habit of, 454.

Interest, in Arithmetic, 601; in Political Economy, 492.

Interjection, in Grammar, 580.

International duties, 477.

Inverness, description and account of, 240.

Invoice. See commercial terms, 501.

Involution and evolution, in Algebra, 606.

Io, a beautiful woman, with whom Jupiter fell in love, and whom he changed into a heifer, to preserve her from the jealousy of Juno. The suspicious Juno begged the heifer, and set Argus of the hundred eyes to watch it; but Mercury, to oblige the superior deity, killed the keeper, and set free the metamorphosed lady.

Ionian islands, description of, 201.

Iphigenia, daughter of Agamemnon. That chief, while

at Aulis, on his way to Troy, was detained by contrary winds, and was told that only by the sacrifice of his daughter to Diana could the Greek fleet proceed in its course. He reluctantly consented; but when Iphigenia was brought to the altar, she suddenly disappeared, and a goat was seen in her place. Diana carried her off, says the story, to be a priestess at Taurica.

IRELAND, HISTORY OF. See History of Great Britain and Ireland, 129-176; description of, 241-256; superficial features, 241; geology, 241; hydrography, 242; climate, 243; botany and zoology, 243; population, 243; national industry, 244; commerce, 245; government and administration, 246; antiquities, 246; province of Leinster specially described, 247; Munster, 250; Ulster, 252; Connaught, 255.

Iris, the messenger of the queen of heaven, and the goddess of the rainbow, the appearance of which was held to indicate a mission of Iris to earth.

Isis, a celebrated female deity of the Egyptians, wedded to her brother Osiris.

Isthmia, solemn triennial games of the Greeks, which derived their name from being celebrated on the Isthmus of Corinth. Combats, races, and athletic sports of every kind, were among the exhibitions, and the poets also contended there for the prize of the bays.

Italian republics, nature of the, 124.

Italy, description of, 198.

Ithaca, a small islet, now called Thiaki, in the Ionian sea, famous as the kingdom of Ulysses.

Ixion, a king of Thessaly, who rendered himself so odious on earth by the murder of his father-in-law, that Jupiter, in misplaced compassion, took him up to heaven. There, however, Ixion behaved so insolently, that Jupiter struck him down to the infernal regions, and ordered him to be tied with serpents to a wheel, which, revolving for ever, rendered his punishment eternal.

Jamaica, island of, described, 315.

January, festival Calendar for, 433.

Janus, one of the primitive kings of Italy, placed after his decease, on account of his equity, among the gods. He was the guardian of gates, and was represented with two heads, probably to indicate the watchfulness required in such custodians. January was named from this deified personage.

Jason, the leader of the Argonauts, with whom he went to Colchis on the Euxine Sea to regain the golden fleece. The king of Colchis promised its restoration if Jason could tame certain flame-breathing bulls, slay a dragon, and perform other difficult feats. Aided by Medea, the king's daughter, an adept in all the arts of enchantment, the chief of the Argonauts accomplished these tasks, and won the fleece; after which he departed secretly, carrying Medea with him as his wife, according to his solemn engagement. Returning home, he found his father Æson too infirm to partake of his triumph; but the art of Medea restored the old man to youth. Jason subsequently became unfaithful to Medea, and, roused to madness, she slew her own children before their father's face.

Jesuit, one belonging to the society of Jesus, founded by Ignatius Loyola, a Spaniard, in 1534.

Jews, the ancient, 75.

Judgment, metaphysically considered, 352.

Jugurtha, an illegitimate nephew of Micipsa, king of Numidia, who slew his cousins, and seized their throne. The historian Sallust has made his name proverbial for cunning, daring, and cruelty.

Julian, an emperor of Rome in the fourth century A. D., usually named 'The Apostate,' from his having deserted Christianity for Paganism, after being trained up to the former faith. He was, notwithstanding, a man of many virtues, and also of superior talents, as his acts, as well as some of his extant writings, sufficiently indicate.

July, festival Calendar for, 441.

June, festival Calendar for, 441.

Juno, sister and wife of Jupiter, and queen of the mythological heaven of Greece and Rome. Her beauty was of a grand and stately kind, and not feminine enough to fix the affections of her husband, whom she annoyed with her jealousies. Her most famous acts consist of persecutions of his mortal mistresses. She was almost universally worshipped, and had splendid temples at Argos, Olympia, Samos, Carthage, and Rome. Her favour was peculiarly implored by women, on account of her being the patroness of marriage and childbirth; and she was also the assigner of power and riches, 86.

Jupiter, son of Saturn and Ops, king of heaven, and ruler of all the gods. Saturn habitually devoured his own children; but Ops deceived him at the birth of Jupiter with a stone, and the child was saved. On reaching the age of one year, he warred with the giant-gods called Titans; and after conquering them, and besides dethroning his father, became the supreme deity and sole wielder of the dreadful thunder. It would be fruitless to go over the actions ascribed to Jupiter, which consist chiefly of low and often ridiculous amours. He was usually represented as a being of majestic countenance, seated on a throne, with a messenger-eagle at his feet, and a thunder-bolt and sceptre in his hands. His chief temples were at Dodona in Greece, and Ammon in Libya, and he had numerous names, corresponding to the site of these or to some of his actions; as *Jupiter Capitolinus* (the Capitoline Jove), and *Jupiter Tonans* (Jupiter the Thunderer), 86.

Jurors, duties of, 468.

Jury, trial by, 62.

Juvenal, an able and unsparing satirist of Rome in the early times of the empire.

KEY TO THE CALENDAR, 433-448.

Keys, diversity of, in Music, 740.

Knives, table, how to clean, 772.

Koran, or record of the Mohammedan faith, 412.

Krishna, in Hindoo mythology, one of the incarnations of the god Vishnu.

La Plata, or Argentine Republic, 310.

Labour, division of, 484; productiveness of, 485; price of, 489; duties respecting, 452.

Labyrinth, any place with so many windings as to render escape from it difficult. The most famous of the several labyrinths mentioned by old writers was the Cretan one, built to confine a monster called the *Minotaur*.

Lachesis, one of the Fates, who spun the thread of life, 87.

Lachrymatory (*Lat. lacryma*, a tear), a small glass vessel or phial found in ancient Roman sepulchres, in which it has been supposed that the tears of the friends of the deceased were dropped, and preserved with the ashes contained in the urn.

Laconia, a Peloponnesian district, of which Lacedæmon was the capital. The people of the region spoke little, and hence the application of the epithet *Laconic* to concise talking or writing.

Lais, a Corinthian courtesan of such beauty and notoriety, that her name has become a synonyme for others in her position.

Lamaism, account of, 408.

Lammas, term and festival of, 442.

Lancaster, House of, in English history, 133.

Land, rent or price of, in Political Economy, 493.

Landamman (*Ger.*), the title given in Switzerland to the chief magistrate of a canton; applied also to the president of the Swiss republic.

LANGUAGE, 17-32.

Language, organ of, in Phrenology, 349.

Languages of the globe, classification of, 29-32.

Laocoon, a Trojan prince, priest of Apollo, who, having offended Neptune, was strangled, with several of his

sons, by two enormous serpents which issued from the sea. This fable has been rendered immortal by an ancient sculptor, whose work on the subject is yet preserved.

Lapitheæ, a family or tribe descended from Apollo, famous for having gained, with the aid of Hercules, a dreadful battle against the Centaurs.

Lares, minor deities, supposed by the Romans to preside over households, and represented by small images, which the possessor always took with him on a change of residence.

Largo (*Ital.*), in music, a slow movement, one degree quicker than *adagio*; *larghetto*, less slow than *largo*.

Latinus, king of the Italian aborigines, who gave his name to the Roman language.

Lefona, mother of Apollo and Diana by Jupiter, and worshipped in many temples.

Lavender-water, how to make, 784.

LAW, HISTORY AND NATURE OF, 49-64; Roman or civil law, 49; canon law, 53; feudal law, 53; law of England, 56; law of Scotland, 62; French codes, 63.

Leander, a youth of Abydos, who, being in love with Hero of Sestos, was wont nightly to swim across the Hellespont to meet her, but was at last drowned in a storm.

Leaping, in Gymnastics, 642.

Lease (*Fr. laisser*), a law term for the conveyance of lands or tenements (usually on consideration of rent or other annual recompense), made for life, for years, or at will; but always for a *less* time than the lessor has in the premises; for if it were for the *whole* interest, it would be more properly an *assignment* than a *lease*. The lessor is he who grants the lease; the lessee the person to whom it is given.

Leda, wife of Tyndarus of Sparta, visited by the enamoured Jupiter in the form of a swan, and mother of Helen, Clytemnestra, Castor, and Pollux.

Leeds, description of, 218.

Leith, description and account of, 237.

Lemonade, recipe for making, 780.

Leonidas, a renowned Spartan, who, when the Persians invaded Greece with several millions of men, took post at the Pass of Thermopylæ with no more than 300 men, and, self-devoted to death, defended it for three days, until he and all his companions perished, after making fearful havoc among the enemy, 91.

Lethe, an infernal river, whose waters made those who drank it forgetful of all the past. Lethe is a poetical synonyme for oblivion.

Letterpress-Printing, 705-720.

Letters, formation of, 18.

Levée (*Fr.*), 1. The time of rising; 2. The ceremonial visits which distinguished persons receive in the morning, or at their rising. In this country, the word is chiefly applied to the stated public occasions on which the sovereign receives visits from such as are entitled, by rank or fortune, to that honour.

Lexicon (*Gr.*), a dictionary or book containing an alphabetical arrangement of the words of a language, with the meaning of each; lexicology, the science of so arranging and treating words; lexicography, the art of writing or compiling a dictionary; and lexicographer, one who writes or compiles such a work.

Libation (*Lat.*), the act of pouring a liquor—usually wine, water, or milk—on sacrificial occasions; also, the liquor so poured out. In familiar language, the liquor drank on festive occasions; synonymous with potations.

Lieutenant (*Fr.*), an officer who supplies the place of a superior in his absence. In the army, the second commissioned officer in a company; in the navy, the officer next in rank to a captain.

Life, duties of, private, 449-464; public and social, 465-480.

LIFE-ASSURANCE, 524-528.

Light and shade, in Drawing, 634.

Lignography (*lignum*, wood, and *grapho*, I draw), an affected term for wood-engraving; hence also *ligno-graph* for woodcut, 721.

## INDEX, AND GLOSSARY OF TERMS.

- Line-engraving, process of, 726.  
 Literary art, in Rhetoric, 701.  
 Lithograph (Gr. *lithos*, a stone, and *grapho*, I engrave), an engraving on a precious stone or gem.  
 Литография, art and practice of, 730.  
 Liverpool, description and account of, 220.  
 Livy, one of the most illustrious of the Roman historians.  
 Lloyd's List—a well-known periodical publication, which contains a full account of shipping intelligence. It derives its name from Lloyd's Coffee-house, so long celebrated as the resort of all classes connected with the mercantile or shipping interest; and its importance in supplying full, trustworthy, and early maritime information, cannot be easily overrated. For an ample account of the origin, rise, and present condition of this establishment, see 'Chambers's Edinburgh Journal,' No. 111, New Series.  
 Loan societies, 536-538.  
 Locality, organ of, in Phrenology, 348.  
 Logarithms, 603.  
 Logging-stones, in England, 215.  
 Logic, 353-368.  
 London, description and account of, 216.  
 Loo, game with cards, 671.  
 Lords, constitution of the House of, 177.  
 Lozenge (Fr.), in geometry, a figure with four equal sides, having two acute and two obtuse angles; in heraldry, a figure on which is represented the armorial-bearings of maidens and widows; in confectionary and medicine, small cakes, so called from their original form, to be chewed or held in the mouth till dissolved.  
 Lucifers, how to make, 781.  
 Lucretia, a young and noble Roman matron, who fell a victim to the licentious passion of the son of Tarquin, king of Rome. After her dishonour, she summoned to her presence her husband and relatives, and, disclosing her injuries to them, took away with her own hands the life which she could no longer endure. Junius Brutus took up the bleeding knife which she had used, and swore upon it to avenge her death, an oath amply fulfilled.  
 Lucretius, a Roman poet, whose work on the 'Nature of Things' (*Natura Rerum*) forms one of the best expositions of the heathen philosophy.  
 Ludicrous, emotion of the, 333-346.  
 Lupercalia (Lat. *lupes*, a wolf, and *arcere*, to defend from), Roman festivals in honour of Pan or Faunus, celebrated on the third day after the ides of February, and repeated on the nones of December, under the name of Faunalia, when the worshippers were clothed with goatskins. These feasts were abolished by Pope Gelasius in 496, on account of the many disorders they occasioned.  
 Lute, a stringed instrument, 768.  
 Lyceum, a name originally given to the place where Aristotle taught, and since applied to establishments in some respects similar.  
 Lycurgus, a celebrated lawgiver of Sparta, whose maxims all tended to make men live simply and plainly, 89.  
 Lydians, the ancient, 79.  
 Lyre, a stringed instrument, 768.  
 Lyric poetry, nature of, 702.  
 Mab, in northern mythology the queen of the fairies, 421.  
 Madness, attacks of, how to proceed in cases of, 776.  
 Madras, description and account of, 271.  
 Mæander, a river of Asia Minor, so notable for its windings as to have originated the word *meander*, bearing that meaning.  
 Mæcenas, prime-minister to Augustus Cæsar, and so highly famed for his countenance of Virgil, Horace, and other men of letters, that a literary patron has since been commonly named a Mæcenas.  
 Mæonides, a name applied to Homer, and from him, in the plural, to the Muses.  
 Magna Charta, or great charter, 131.  
 Maia, mother of Mercury, by Jupiter.  
 Malay variety of mankind, physical and mental characteristics of, 5.  
 Malaysia, geographical description of, 281.  
 Malthus, his theory of population, 513.  
 Mammalia, design in the structure of, 377.  
 MAN, PHYSICAL HISTORY OF, 1-16.  
 Man, relation between and external nature, 371.  
 Manchester, description and account of, 217.  
 Mânés, a term applied by the ancients to the souls of the dead.  
 Mankind, distribution of, 6; differences in anatomical structure, 7; physical character, 10; mental character, 14; permanency of types, 16.  
 Manners, good—politeness, 457.  
 Manufactures, British, statistics of, 185-186.  
 Marathon, a plain of Attica, where Miltiades the Athenian, with comparatively a mere handful of men, routed the vast army of the Persians, 91.  
 Marble hearths and chimney-pieces, how to clean, 771.  
 March, festival Calendar for, 437.  
 Marius, a Roman of celebrity, who, from the rank of a peasant, raised himself by his talents to the highest offices of the state. Reduced at one time to the greatest danger and distress, he fled to Africa, and, himself then a ruin, he sat down on the ruins of Carthage. Again obtaining power, Marius glutted his vengeance by the most inhuman massacres, and died amid the blood he had spilt, 105.  
 Marlborough, his campaigns, 155.  
 Marriage, social nature of, 33; duties connected with, 469.  
 Marriages, statistics of, 546.  
 Mars, the god of war, son of Jupiter and Juno. He was represented as an armed figure in a chariot, driven by Bellona, and drawn by two horses, which the poets named Terror and Flight.  
 Mary, queen of Scots, 136-138.  
 Masters and servants, duties of, 472; relations of, 771.  
 Mausolus, king of Caria, so dearly beloved by his wife, that at his death she drank up his ashes, and erected to him a monument so splendid as to be deemed one of the seven wonders of the world; hence the modern word *mausoleum*.  
 May, festival Calendar for, 440.  
 Mayor, chief municipal magistrate in England and Ireland, functions of, 45.  
 Measure or rhythm, in Music, 739.  
 Measures and weights, British, 597.  
 Medea, princess of Colchis, and wife of Jason, celebrated for her magical arts, her restoration of the youth of Æson, and her murder, when infuriated by jealousy, of the children born by her to her husband.  
 Medea, history of, 79.  
 Medusa, one of the Gorgons, whose frightful snake-encircled head turned the beholders to stone. She was slain by Perseus, who placed her head on Minerva's shield, thence rendered unendurable by mortal eyes.  
 Meetings, public, conduct at, 466.  
 Mehemet Ali, late pasha of Egypt, notice of his life and doings, 277.  
 Meleager, an ancient hero, celebrated for slaying the monstrous Calydonian boar.  
 Melody, in composition, 691; in Music, 737, 743.  
 Melpomené, the Muse who presided over tragedy.  
 Memnon, an aboriginal Ethiopian or Egyptian king, to whose memory the people of Thebes raised a colossal statue of black marble, which had the wonderful power of emitting musical sounds when struck by the rays of the rising and setting sun. Most writers ascribe this phenomenon, which is often adverted to, to the jugglery of the priests; but some modern travellers, who have visited the yet extant ruins of the statue, have fancied that it emits sounds even at this day.  
 Menelaus, king of Sparta, the abduction of whose wife Helen by Paris caused the Trojan war.

- Mensuration, in Arithmetic, 602; in Geometry, 615.
- Mentor, a name which Minerva assumed when she became the guide of Telemachus in his wanderings; hence arises a familiar title for a counsellor.
- Mercury, otherwise called Hermes, son of Jupiter and Maia, and herald of the gods. He presided over oratory, commerce, and thieving, and conducted the spirits of men to the infernal regions, 86.
- Metaphor, in literary compositions, 691.
- METAPHYSICS, 321-336; logic of, 368.
- Metonymy, in Rhetoric, 692.
- Mexico, description and account of, 304.
- Mezzotinto, a species of engraving, 727.
- Mice, how to destroy, 774.
- Michaelmas-day, term and festival, 443.
- Midas, a Phrygian king, who, having done a favour to Bacchus, was requested by the god to ask what reward he chose, and, out of foolish avarice, requested that all he touched might become gold. As his very food was converted into that metal, he soon besought the withdrawal of the gift, and was freed from it by bathing in the river Pactolus, the sands of which were turned to gold. For subsequently preferring the music of Pan to that of Apollo, the latter gave Midas the ears of an ass.
- MIDDLE AGES, HISTORY OF, 113-128.
- Milo, an athlete of old, famous for his great strength. He could carry a large ox, kill it with a blow of his fist, and finally eat it up in one day.
- Miltiades, the illustrious Athenian who commanded at Marathon, and afterwards died in prison, a sad monument of human ingratitude.
- MIND, THE HUMAN, 321-336.
- Minerals, how to keep, 781.
- Minerva, goddess of wisdom, war, and the arts and sciences, who sprung completely armed from Jupiter's brain, according to the fable, without a mother. She is described as one of the most chaste and respectable of all the deities; and though swayed at times by passions far from divine, was a great benefactress of mankind, who owed to her most of the liberal arts. The name of Pallas was as often given to her as Minerva; and from being the patron deity of Athens, she was also called Athena, 87.
- Minim, in musical time, 739.
- Minion, a variety of type, in Printing, 709.
- Minos, a famous king and lawgiver of Crete, who, for his equity, was appointed one of the judges of the spirits of men after his decease. A monster called the Minotaur was shut up in the labyrinth of Dædalus; and Minos, severe though just, gave it the captive youth of Athens to devour, till Theseus slew it.
- Misfortunes, our duty regarding, 474.
- Mithridates, a name borne by several kings of Pontus, one of whom, a man of supereminent talents, had such a knowledge of pharmaceutical herbs that he could counteract the effect of the most deadly poisons; hence the use of the word *mithridate* as a synonyme for an antidote to such drugs.
- Mnemosyné, the goddess of Memory, and mother of the nine Muses by Jupiter.
- Modulation, in Music, 754.
- MOHAMMEDANISM—MOHAMMED, 408-416; also 115.
- Momus, the god of fun and pleasantry, jester-general and satirist of the mythological heaven.
- Monarchy, monarchical governments, 41.
- MONEY, origin and nature of, 503; coined money, 504; paper money, 505; in Political Economy, 491.
- Mongolian variety of mankind, physical and mental characteristics of, 4; history of, 67.
- Monogamy (Gr. *monos*, one, and *gamé*, marriage), marriage with one wife, 33.
- Montserrat, British West India Island, 317.
- Moot or moot-hills, in Scotland, 235.
- Moral Philosophy—Ethics, 383.
- Morpheus, son and minister of Somnus, the god of Sleep. He visited mortals in dreams.
- Mortality, bills of—accounts of the number of births and burials within a given district for every week, month, quarter, or year. See POPULAR STATISTICS, 545-557.
- Mortality, effects of seasons on, 551; effects of wealth and civilisation on, 552; effects of increased wealth and knowledge on, 555.
- Mortality, rates of, in Life-Assurance, 525.
- Multiplication, in Arithmetic, 595; in Algebra, 605.
- Mummies, Egyptian, 72.
- Muse, the nine Muses, daughters of Jupiter and Mnemosyné. Apollo was their patron, and the conductor of their orchestra. From certain spots consecrated to them, the poets call them the Pierian, Castalian, and Anonian maids, 87.
- Music, 737-768.
- Muslin dress, how to clean, 774.
- Myrmidons, an attached band of Thesalians who accompanied Achilles to the war of Troy. Eager followers of any description are familiarly called by this title, as 'the *myrmidons* of the law.'
- Naiads, certain minor goddesses who presided over springs, fountains, and rivers, 87.
- Nails, how to clean the, 783.
- Napoleon, wars with, 168-172.
- Narcissus, a beautiful youth, who pined away and finally killed himself through love for his own image, as reflected in a fountain. He was said to have been changed into the flower which bears his name.
- Navy and army of Britain, 184.
- Negro (Lat. *niger*, black) family, in Ethnology, 4; in History, 65.
- Neighbours, our duties as, 468.
- Nemesis, the goddess of vengeance, implacable to the bad, but kind to the virtuous.
- Neptune, god of the sea, which element was assigned to him when Jupiter and Pluto, the two other chief deities, assumed the sway of the other portions of the universe. Neptune was represented in a chariot of sea-shell, drawn by horses with wings, and in his hand he held a trident, the emblem of his authority, 86.
- Nereus, a minor deity of the sea, represented as an old man with a long beard, attended by fifty sportive maids, his daughters, who were called Nereids, and were worshipped by the ancients.
- Nero, a Roman emperor, proverbially infamous for his crimes and vices. Originally a youth of promise, Nero was quickly changed in character by the unbounded rule, too much for a mortal to possess, which was then attached to the imperial throne. He assassinated his own mother, and, for the mere luxury of the sight, set fire to the city of Rome. His employment during the fatal conflagration is shown by the sentence, 'Nero fiddled while Rome was burning.' He died by his own hands, to escape the fury of his outraged countrymen.
- Nestor, king of Pylos, who, at a very advanced age, went to the Trojan war; and is so highly lauded by Homer for his eloquence, that posterity have adopted his name as a synonyme for a wise and venerable old man.
- New Britain, in North America, 292.
- New Brunswick, description and account of, 296.
- New Grenada, republic of, 308.
- New South Wales, account of, 283.
- New Zealand, settlements of, 286.
- Newcastle-on-Tyne, description and account of, 221.
- Newfoundland, general account of, 297.
- Nice, Council of, 397; creed, 397.
- Niello (Ital.), a species of engraving, 726.
- Nile, the, description and account of, 276.
- Niveveh, ancient city of, 77.
- Nomades, Nomadic society, 36.
- Normans, conquer Britain, 130; their early kings, 131.
- Norway, geographical description of, 206.
- Notation, in Arithmetic, 593.
- Noun, in Grammar, 577; inflection of, 581.
- Nova Scotia, description and account of, 295.
- November, festival Calendar for, 444.
